In Memoriam
Reuben Hersh (1927–2020)
Sometimes being kind is more important than being right
Yuri Manin (1937–2023)
Good proofs are proofs that make us wiser
Chandler Davis (1926–2022)
The mathematics tells truth about the world
We are its ventriloquist, yet
some words it won't let us put in its mouth
&
C and K
for their unwavering support through the vicissitudes of the years. . .

Preface

This book is the outcome of co-operation between the communities of mathematicians, philosophers, and historians of mathematics. I would like to thank the editorial advisory board consisting of eminent scholars working in the aforementioned communities for being a part of this project. Next, I am grateful to the section editors for shaping their respective sections and the authors who contributed to these sections. Finally, I would like to mention specific individuals without whom this book would have been difficult to accomplish logistically. These individuals are Thomas Hempfling (Springer/Birkhaüser), Sarah Annette Goob, and Ruth LeFevre (Palgrave).

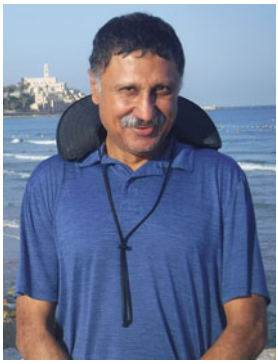
About the Editor



Bharath Sriraman is a Professor of Mathematics at the University of Montana-Missoula working in the areas of cognition, creativity, mathematics, and philosophy. In 2016, he was named the University of Montana Distinguished Scholar. Prof. Sriraman has held 40+ visiting professorships at institutions in Norway, Iceland, Sweden, Germany, Turkey, Iran, Malaysia, South Korea, Canada, South Africa, Colombia, and Argentina, which include two US Fulbright awards. To date, Prof. Sriraman has published more than 330 journal articles, book chapters, proceedings papers, and reference work entries, and served as the Editor of 33 volumes, in his areas of interest. He is the founder and Editor-in-Chief of *The Mathematics Enthusiast*, an independent, peer-reviewed, open-access international journal. In addition to editing and curating the *Handbook of the History and Philosophy of Mathematical Practice*, he previously served as the Editor-in-Chief of the *Handbook of the Mathematics of the Arts and Sciences* (Springer, 2021). In keeping with the adage *Omne Trium Perfectum*, his third Major Springer Reference Works Project is the Handbook of Visual, Experimental and Computational Mathematics: Bridges Through Data in preparation for release in 2027. In his spare time, he is an amateur arborist.

From Origins to the Natural Historians/Philosophers

Bharath Sriraman

Introduction to the Handbook of the History and Philosophy of Mathematical Practice

Bharath Sriraman

Abstract

This Handbook offers a comprehensive survey of the story of mathematics and its practices. It is neither her story, nor his story, but story. In order to do so, the 100+ chapters spanning 3200+ pages in four volumes examine our collective mathematical practices over time and ways in which this shaped its history and philosophy. "Mathematical practice" is left as an undefined term in order to allow the reader to conceptualize it in whatever way they choose to. The book was inspired by conversations with three eminent souls Reuben Hersh, Yuri Manin, and Chandler Davis and is dedicated to them in memoriam.

Keywords

Origins · Natural history · Natural philosophy · Mathematicians reflections · Influences in twentieth- and twenty-first-century mathematical practice · Probability · Constructing the reals · Paradoxes and foundations · Euclidean and non-Euclidean geometry · Logic · Proof · Ontology · Pluralism · Experimental mathematics · Views from other domains · New perspectives · Semiology of mathematical practice · Reuben Hersh · Yuri Manin · Chandler Davis

1 Introduction

It is apropos that the introduction to this Handbook and its completion occurs in Old Jaffa. Reuben Hersh's progenitor landed on these shores to escape the clutches of Pilsudski's army in Poland more than a century ago, to emigrate yet again to America in 1920. This Handbook is dedicated in memoriam to three individuals, namely, Reuben Hersh, Yuri Manin, and Chandler Davis. Reuben played an important role when I was conceptualizing it and offered his generous help. I was asked "Why are you doing this?" My reply was a cheeky "Deeds not words" (Emmeline Pankhurst's words), to elicit loud laughter from Vera John-Steiner who remarked ". . .which will require many, many words!" Keeping with another thing, I learned from Reuben and Vera, "Be pithy but draw in the reader," I will be as succinct as possible. Yuri Manin and Chandler Davis also offered valuable advice in crafting this book. Yuri's advice was to draw in the collective knowledge of the community that engages in mathematical practice to have something that makes us wiser, like a good proof. Chandler's tremendous gift with words (prose and poetry) in addition to his convictions helped me to get to the finish line. Alas, all the individuals mentioned here are no longer with us. It is my hope that this book channels their spirit and courage.

This Handbook offers a comprehensive survey of the story of mathematics. It is neither her story, nor his story, but story. In order to do so, it seemed wiser to examine our collective practices over time and ways in which this shaped its history and philosophy. What is "mathematical practice" then? It is an undefined term as far as I am concerned. The contents of the book will perhaps aid the reader in conceptualizing it in whatever way they choose to.

The book has been organized in four volumes consisting of 14 sections in all, and 100+ chapters. Each volume is self-contained and offers a different starting and ending point in the telling of the story of mathematical practice(s). Volume 1 consists of sections: (a) From Origins to the Natural Historians/Philosophers; and (b) Mathematician's Reflections on Practice and Working Philosophy of Mathematics. Volume 2 contains (c) Influences in Twentieth and Twenty-First-Century Mathematical Practice; (d) Practical, Historical and Philosophical Instances of Probability, and (e) Constructing the Reals: Paradoxes and Foundations. Taken as a whole, the first two volumes offer more or less a complete story of mathematical practice including reflections from those who had to practice mathematics in highly unusual sociopolitical conditions in the twentieth century. Volumes 3 and 4 become more technical in their rendition and cover the following topics (f) Practices in Euclidean and Non-Euclidean Geometry; (g) Logic; (h) Proof; (i) Ontology; (j) Pluralism; (k) Experimental Mathematics (not in a strictly Borweinian sense); (l) Views from Other Domains; (m) New Perspectives; and finally (n) Semiology of Mathematical Practice.

Taken as a whole, this Handbook has been a labor of love, and I hope it is of some value to all those who engage in mathematical practice.

Abstract

In this chapter, the authors engage in a dialogue on what constitutes mathematical practice from pre-Socratic Greeks onto the advent of natural philosophy. The conversation occurred through dialogues between the authors over the period 2016–2019. A coda with relevant content from the Origins section is provided.

1 A Conversation

H = Hersh; S = Sriraman

S: What would be a good starting point for the opening section on Origins? We could start with the Pythagoreans?

H: Pre-Socratic might be a better way to characterize it. Poor Pythagoras has been turned into an academic industry. Have you seen the book on Ancient Loons?

S: The one by Davis? I was supposed to do a review of it, but it seemed too esoteric in my opinion. The book was very anecdotal since it reported on email conversations between Pingree and Davis, a bit like what we have been doing for over a decade. There is a chapter on Pythagoras in it and parts of the book are euphemistic in my opinion.

H: Is Carlo (Cellucci) doing a chapter in the opening section?

S: We agreed on a topic related to what mathematical objects really are. It seemed related to the book he is currently writing and fitting to be in the opening section of the book.

H: Do you know at which point he starts tracing the history of mathematical objects?

S: Apparently Herodotus writes of an Egyptian King asking the nature of mathematical objects. I don't think there is too much emphasis on ontology per se. There will also be a chapter from Ulf Persson on Platonism.

H: He (Ulf) visited me many years ago. He has had an interesting career. Is he going to get into metaphysics? We had some conversations about Platonism as well if I remember correctly.

S: I have given free rein in the sense that there is a lot of misappropriation of the expression "Platonism" – it seems it is used differently by philosophers as opposed to things written about the psychology of mathematics and those doing mathematics education. One could also say Poor Plato. Ulf wants to get into the physics or science of things. From what I understand in our email exchanges, he wants to compare mathematical objects to atoms – if one believes in the existence of the latter, does that have any implications for believing in the former?

H: My use of Platonism is quite clear – you can call it mathematical Platonism as it pertains to the practice of mathematics. People get too hung up with the ontology of things which I have come to now think of as nonsensical. I found a thesis from someone called Rittberg that was recent. I haven't had the energy to read it yet. You may want to look at it and invite him.

S: I will read it. Have you changed your view about pluralism as you wrote in the Festschrift? I recall the paragraph about the Bourbaki where you wrote that formalism was a kind of a front to hide behind when they were confronted with paradoxes.

H: . . .and Realism is what they really believed in. One would think they were schizophrenic. I talked about this as being a sort of duality. Accepting our mental models of objects as real and getting agreement with other mathematicians suggest a sort of sociocultural realism. This is not Platonic realism per se,

although one can argue for consistency of these two views or compatibility. Pluralism is not really a philosophical position. Tell me about the full handbook.

S: My goal is to split it up into sections starting with Origins. Believe it or not, I promised Springer about 100 chapters! I am getting mathematicians, historians, and philosophers involved, so it is supposed to be a handbook on the history and philosophy of mathematical practice. You did read the proposal I sent to Springer; there are sections on ontology, logic, pluralism, semiology, experimental mathematics, proof, and new perspectives in addition to sections on constructing the reals, reflections from mathematicians, views from other domains, and maybe probability.

H: It was very well written. I am glad you are focusing on practice; people still do not understand or know what mathematicians do. You have to bear in mind that philosophers typically theorize about mathematics; they are not really interested in the activity of doing mathematics or the mathematics, although some have started to theorize about mathematical practices. The former results in models which as we know people argue about back and forth – take a position, the latter in more nuanced – mathematical practice is about the activity of doing mathematics. Maybe this will renew an interest in the messy part of doing mathematics. I am unsure whether philosophers will delve into this.

S: There might be a schism in what historians will write as opposed to what philosophers will write. I am not too worried. Creating the links will be for the astute reader. I also asked Yuri and Chandler for help with finding interested authors. Do you have any suggestions in terms of significant shifts in practice? I am thinking of breaking it down into historical periods, but the danger in doing this is that it would seem the development of practice as being linear and not indicating jumps when something significant comes along like a change in notation.

H: Such as?

S: If you consider the Arithmetica in its original notational form which was rhetoric, syncopated, and symbolic with use of the Greek alphabet and special symbols, and see the modern treatment of arithmetic of algebraic curves, one sees a significant shift in the practice of Diophantine arithmetic. Now the study of elliptical curves is a specialty on to itself. I am also hoping to clear up the misappropriation of both Plato and Pythagoras. I don't think mathematics had the same status as philosophy for Plato and like anything else people write all sorts of thing without reading the original texts. I know people from Stelios' circle – real Greeks who might step up to the plate.

H: Negrepontis? Good – the more diverse the people you find in terms of expertise, the better the book will be. Did you know there was a beautiful book that was published in the Dolciani series by Isabella Bashmakova that goes along what you were saying about practices in Diophantine arithmetic. I don't often use the adjective "beautiful," but in this case, it applies. Have you thought of writing a chapter on Descartes, or perhaps Leibniz?

S: I already have an author writing a chapter on Leibniz' binary arithmetic. My main idea is to indicate shifts in practice by tracing it forward to the period of

natural philosophy and perhaps even further. I mean a lot of so-called mathematical practices were inspired by problems in astronomy and later physics. There are also other ways to unfold practice as in how Euclidean geometry inspired a lot of new practices involving proportionality such as the logarithm. Napier's original axioms built off of Euclid in the notion of progressions or comparing arithmetic and geometric progressions with notation and arithmetic that is completely different from what modern books suggest. Or even the development of algebra, although this has been done a lot in books that give a historical approach to the study of abstract algebra.

H: You may want a separate section just on geometry? There are significant shifts in practice in its history. There are plenty of books on the topic. How will you develop this topic?

S: Yes, I am teasing out the practices in Euclidean geometry in a different section focused on practices in Euclidean/non-Euclidean geometry. My intention is to get someone who knows the work of Menelaus to write about practices in spherical geometry that predated the fashionable Gauss/Lobachevsky/Bolyai triage, which overshadows it. It also offers a chance for people to learn about the Arab contributions to mathematical practices, since they had translated Menelaus' Spherica.

H: If you are going the natural philosophy route, the choices are limitless in terms of cherry picking which or what practices changed. You should make it clear that these were your choices. You know I probably won't be around to see the book in print.

S: Please don't say that. Regardless, the book will be dedicated to you posthumously. However, if you believed in Gilgul like your distant ancestors, you might see it in a different form. . .

2 Coda

Reuben Hersh passed away on January 3, 2020. We planned on writing this introductory chapter together once all the chapters for the Origins section had materialized. In the 3 years since his passing, the Origins section developed into the *largest* section of the handbook with mathematical practices described over two millennia, from the Pythagoreans onto the work of René Thom in the twentieth century.

Cellucci's chapter on the nature of mathematical objects opens the section on Origins. It considers mathematical objects as

> "independently existing entities, or abstractions, or logical objects, or simplifications, or mental constructions, or structures, or fictions, or idealizations of sensible things, or idealizations of operations."

Persson's chapter examines misconceptions in the use of Platonism. In particular, it takes "exception to the post-Plato development of Plato's Platonism, the so-called Neo-platonism, which is an exalted version of Plato's thought but shorn off its irony." Persson writes,

> ". . .it constitutes a literal reading of Plato's metaphor positing a separate abode for forms and interpreting the immortality of the "soul" in personal terms. Those religious ideas are but a distraction irrelevant to the issue of mathematical Platonism, but unfortunately providing easy fodder for contemporary attacks and dismissals of it."

While Cellucci argues for mathematical objects as hypotheses introduced to solve mathematical problems by the analytic method, Persson uses Physics as an example of a human activity and compares mathematical practice in many ways analogous as a collective feat of human imagination. In both of these chapters, mathematical objects are not conferred any special ontological status.

Plotnitsky's chapter clears up the misappropriation of the terms "Pythagorean" and "Platonism" by explaining clearly what Pythagorean thinking entailed in terms of the logos and the alogon. By delving into original sources to distinguish between Pythagorean thinking and Platonist thinking, the intended meaning of the status of mathematics for Plato becomes clear. Plotnisky writes:

> While Plato conceived of the ultimate architecture of the ideal realm on the *mathematical* model, he distinguished the philosophical thinking he aimed at from *mathematics*, at least the mathematics as practiced by mathematicians of his time. Plato thought that only philosophy, and specifically dialectic, could achieve, for humans, the maximally close proximity to the ultimate architecture of (ideal) reality. He expressed doubts that mathematics as a technical discipline, or at least mathematicians could do so, given their (Pythagorean) attitude, too tolerant of the presence of the alogon with the logos of mathematics, however, circumvented this presence may be.

The different chapters of the Origins section examine in depth:

(a) The spirit of the Pythagoreans that lingers in algebra and geometry
(b) Different meanings and the metaphysical aspects of Platonism
(c) How definitions, concepts, and heuristics develop in mathematical practice
(d) The influence of natural philosophy in the contributions of Descartes, Fermat, Leibniz, and Euler; and last but not least
(e) Evolving notions of measurement, abstraction, and consistency in mathematics

Taken as a whole, the Origins section provides a substantial glimpse into the changing nature of mathematical practices over the course of 2500 years. It culminates with a chapter on René Thom, in which one learns of his connection with the work of Aristotle and to those of Leibniz, Riemann, and others.

Abstract

This is a personal view of and commentary on Yuri Manin's relationship with mathematics, philosophy, literature, poetry, art, and culture. His life epitomized those of the great natural philosophers of yore.

1 Introduction

Yuri Manin passed away a few months ago. Such a loss, even if in principle is to be expected, always comes as a shock, and in Manin's case, it is a collective shock. He was an important editorial advisor of the present Handbook. Bharath Sriraman, the chief editor, asked me to write an article on Manin, and at the same time, he told me that it was Manin who had recommended me as coeditor. I am happy to render him this small tribute. It goes without saying that I would have preferred not to have to write it, and that, instead, Manin would have been able to see this Handbook.

I will not make the praise of Manin as a mathematician, because, first, it is well known that he was a first-order mathematician whose works on algebraic geometry, number theory, mathematical physics, complexity theory, computing, and probably other fields have had a crucial impact on the development of all these domains, and secondly, and most of all, it is difficult for me not to follow Jules Tannery's aphorism: "Il est des hommes auxquels on ne doit pas adresser d'éloges, si l'on ne suppose pas qu'ils ont le goût assez peu délicat pour goûter les louanges qui viennent d'en bas." (There are men whom we should not praise, unless we assume they have the rather indelicate taste for praises that come from below.) (Tannery 1912, p. 102). Instead, I would like to talk about some aspects of Manin's thinking and life that are less known to those who have only heard of his purely mathematical work.

Manin was thoroughly involved, besides mathematics, in philosophy, linguistics, psychology, sociology, history, literature, and poetry. In fact, mathematics, for him, was part of the vast field we call "culture," in which his thought was evolving in several directions at the same time. Even in his mathematical writings, he often addresses social, cultural, and philosophical issues. This chapter will be a quick review of some of Manin's relationships with all these domains, relationships that he lived on a daily basis. The word mathematics will only appear because it is part of the expression "philosophy of mathematics."

2 Tarkovsky

I will begin with a personal recollection: a conversation I had with Manin on July 21, 1994.[1] I was visiting the Max-Planck-Institut in Bonn for a few months. Manin had already joined this institute as a permanent professor,[2] and it was the first time I talked with him. A few days before, I was in Paris, and I had purchased there a book by Andrei Tarkovsky, his *Diary* of the years 1970–1986, in French translation, published by the *Cahiers du Cinéma* (Tarkovsky 1994). On that day of July 21, I had just finished reading it. Tarkovsky recounts in his diary his everyday life in

[1] I can tell the exact date because I keep a diary.

[2] In fact, Manin was hired as one of the directors. The Max Plank Institutes have no "permanent professors" but only directors. (I thank J.-P. Bourguignon for this clarification.)

Moscow, his troubles with censorship,[3] his exile in Italy, his illness, and the last days of his life, in Paris. One may also read there, among many other things, Tarkovsky's reflections on art and literature. Figures like Bergman, Bresson, Dostoevsky, Bach, Pushkin, Shakespeare, Solzhenitsyn, Rostropovich, etc. are present throughout the book. In the first pages, Tarkovsky mentions Manin.

On that day, at the 4 o'clock tea of the MPI, I met Manin. I asked him: "Do you know that Tarkovsky talks about you in his book?" He responded with a question: "Which Tarkovsky?" For a fraction of a second, I was puzzled by his question, but then I realized that Manin, like all educated Russians, knows that there are two Tarkovskys: Andrei, the filmmaker, and his father, the poet Arseni Tarkovsky, whose poems resonate throughout the film *The mirror*. I told him "the filmmaker," with a hand gesture, that of someone who is shooting a film. He was not aware of this. I had the book in my office. I fetched it and I showed him the spot. He was visibly moved. He leafed through the book, photocopied a few pages and asked me to buy one copy for him when I go back to France. I told him I would.

On the next day, I saw Manin anew, at tea time, and we talked again about Andrei Tarkovsky. He told me that he had met him twice: the first time, at Moscow University, where the latter had come to present his film *Andrei Rublev*, and the second time, at the home of Otar Iosseliani, who (I learned this from Manin) had studied mathematics before starting his career as a filmmaker. We also talked about Krzysztof Zanussi, who (I also learned this from Manin) prior to embarking on a career in cinema, studied physics. I told him that Tarkovsky mentions Zanussi in his memoirs, toward the end, when the latter lent him his apartment in Paris.

Here is what Tarkovsky writes in his diary on September 1, 1970:[4]

> Going through old papers I came across the transcript of a university debate on Rublev. God, what a level. Abysmal, pathetic. But there is one remarkable contribution by a maths professor called Manin, Lenin Prize winner,[5] who can hardly be more than thirty. I share his views. Not that one should say that about oneself. But it's exactly what I felt when I was making Andrei. And I'm grateful to Manin for that.

Here are now, according to the same diary, an excerpt of what Manin said on that occasion:

> Almost every speaker has asked why they have to be made to suffer all through the three hours of the film. I'll try to reply to that question. It is because the twentieth century has seen the rise of a kind of emotional inflation. When we read in a newspaper that two million

[3] From Tarkovsky's diary, one gets the impression that these troubles arose not because of an opposition to the authorities, but because of the spiritual themes that are present in his movies.

[4] For all these quotes from Tarkovsky's book, I am using the English translation which appeared in 1994 (Tarkovsky 1994).

[5] [My note] The Lenin prize was one of the most prestigious prizes (maybe the most prestigious one) of the Soviet Union. Manin received it in 1967. Among the other recipients, let me mention Andrei Sakharov, Sergei Prokofiev, Dmitry Shostakovich, Sviatoslav Richter, and, among the mathematicians, Vladimir Arnol'd and Andrei Kolmogorov.

> people have been butchered in Indonesia, it makes as much impression on us as an account of our hockey team winning a match. The same degree of impression! We fail to notice the monstrous discrepancy between these two events. The channels of our perception have been smoothed out to the point where we are no longer aware. However, I don't want to preach about this. It may be that without it life would be impossible. Only the point is that there are some artists who do make us feel the true measure of things. It is a burden which they carry throughout their lives, and we must be thankful to them.

Tarkovsky comments: "It was worth sitting through two hours of rubbish for the sake of that last sentence."

A few days later, I talked again with Manin about Tarkovsky's memoirs, and this time I wanted to ask him about Djouna, an astrologer-medium-paratherapist who practiced in Moscow, of whom Tarkovsky speaks all throughout his diary. She used to treat cancer and all other kinds of diseases by paramagnetism. Tarkovsky, who speaks of her as "an uneducated and capricious woman, a mountain woman," was being treated by her, and he used to advise his friends to do the same. At some point, she became ill, and Tarkovsky cared for her, using her own methods. Incidentally, when Tarkovsky arrived in Italy, he met another healer – "of Djouna's type," he writes – who predicted his future.

I was puzzled by all this and I asked Manin if he had heard of Djouna. He responded: "Of course! everyone in Moscow has heard of her." I told him that I was surprised by the fact that Tarkovsky was so close to her, and he said: "If you had known Moscow in the 70s and 80s, you would not be surprised." At that moment, I thought of Mikhail Bulgakov's *Master and Margarita*, with its supernatural, nonconformist, spiritistic side, where you meet witches, black magic, etc. All the Russian mathematicians I know have read it.[6] In fact, I understood later that I was wrong, that paramagnetism and hypnosis have nothing to do with magic, that they are part of science, of medicine.[7]

Manin talked, at several occasions, about Moscow in the 1960s–1980s, which hosted a cultural community consisting of small or larger circles, including mathematicians, artists and poets, a community one could find in Moscow and Leningrad and probably nowhere else in the world in terms of vigor and enthusiasm. In the speech he made at his reception ceremony as a foreign associate at the Paris Academy of Sciences (Manin 2006),[8] he recalls:

> Moscow of the 1960s–1980s, where I spent the most creative time of my life, was also boiling with humanities studies and quests for meaning of human culture, history, and psychology. I was happily participating in seminars and conferences organized by my

[6] I learned later on that Bulgakov was a medical doctor, just as Chekhov was. Incidentally, Bulgakov wrote a book titled *A country doctor's notebook*, in a very classical style (unlike *The master and Margarita*), which he thought of as a parallel to Chekhov's medical tales.

[7] I also know that the oncologist Léon Schwartzenberg, who was treating Manin and who, together with his partner Marina Vlady had become close to him during the last moments of his life, declared once that he could not do his treatment on Tarkovsky in an efficient manner because the latter refused to take the classical drugs.

[8] The passage is also included in the introduction of (Manin 2007).

> friends linguists and philologists, delivered talks and published amateurish papers on subjects ranging from the trickster figure in mythology to the epistemology of Lévi-Strauss.

Manin talks here about the period before he left to the West. From what I know, this form of culture is still bubbling today, in Moscow and Saint Petersburg, in the form he describes. As a matter of fact, Manin was among the Russian mathematicians living in the West who returned regularly to their home country.

Several years later, I thought about my conversation with him about Tarkovsky and magnetism, especially after I watched Tarkovsky's *Mirror*, a film that opens with a scene where a young stuttering child recovers his speech thanks to a therapy that mixes magnetism and hypnosis. I thought about Manin because I knew that language and linguistics were among his favorite research subjects all throughout his life, and that in his theory, hypnosis plays a fundamental role. For example, in his essay *The early development of speech and consciousness (Phylogeny)*, reprinted in (Manin 2007), he discusses works of several scientists on hypnosis and he describes a number of hypnosis experiments in which the researcher makes, as in Tarkovsky's *Mirror*, verbal suggestions and studies their effects on the patient's behavior. In the same essay, Manin reports on instances of auditory hallucinations, discussing the part played by consciousness in the behavior of an individual. He recalls that "hypnosis became possible only after development of speech" (p. 176 of the English version of (Manin 2007)). In the same essay, he writes:

> For many years I led a seminar in Moscow on psycholinguistics and evolution of mind and consciousness. Among its participants and contributors were linguists, ethnologists, neurobiologists, psychologists and psychiatrists. All of us had different backgrounds and different interests, and we tried to find common viewpoints and problems that might possibly be clarified by throwing together our diverging experiences.

I will say more about Manin's ideas on language and linguistics below.

Almost three decades after my first conversation with him, we talked again about Tarkovsky. It was during covid period. I am extracting from an email Yuri sent me on March 20, 2020, with the subject "Tarkovsky":

> [. . .] We have also stopped listening or reading news, although Xenia once a day browses some *Zeitung* in the Web. I am trying to be quiet and keep my feelings. My ultimate joke about all of it: after all, we have read Gogol, Kafka, etc. [. . .] Let's hope that this crazy time will soon pass. Yesterday my son from Palo Alto sent me an email with subject "Let us watch Tarkovsky", with the address [. . .]

Manin sent me the address of a website where one can watch free of charge all of Tarkovsky's movies and which I am happy to use until now. I then reminded him of our 1994 conversation about Tarkovsky's diary. In his answer, he gave me a few more details about his intervention in the debate that took place at the university, after the film projection:

> It was the first ever public screening of *Rublev*; it was at the Moscow University Club (a former Orthodox Church, now again). I was then a young math professor at the university, and I was

invited to attend it. After the screening, several persons from the public (I do not know who, probably, a party committee required it from them) delivered very critical speeches. I was very angry, ran to the podium and defended Tarkovsky and his creativity. I have long forgotten exactly what I said, but Andrei kept a rendering of my words in his diary.

3 Mathematics and Language

In his Kyoto ICM talk (1990) (Manin 1990), Manin presents mathematics as "a specialized dialect of natural language, and its functioning as a special case of speech." Language is complex, a complexity which is that of man. In several works, Manin considers mathematics, like language, a *metaphor*. He explains the meaning he gives to this crucial word by referring to a sentence in the book by J. P. Carse, *Finite and infinite games* (Carse 2013), according to which a metaphor is the "joining of like to unlike such that one can never become the other [. . .] At its root all language has the character of metaphor, because no matter what it intends to be about it remains language, and remains absolutely unlike whatever it is about."[9] Language is also an essential component of the talk Manin gave at his reception to the Paris Academy of Sciences (Manin 2006). He declares there: "Language and its functioning, both in contemporary mathematics and mathematical logic, and at its very early pre-historical stages about which we can only speculate, permanently fascinated me."[10] From this talk, we learn that it is in his effort to understand the linguistic dimension of mathematics that Manin was led to an extension of the notion of Kolmogorov complexity, to the initiation of the project of quantum computation, and to his contribution to the theory of error-correcting codes.

Since I mentioned the work of Kolmogorov, and since my article opens with references to Tarkovsky's *Diary*, let me report on the following. By the beginning of 1972, Tarkovsky's third feature-length film, *Solaris*, was finished, but it had still to pass several censorship committees. Tarkovsky gives a list of the observations, questions, corrections, and recommendations that he received from various bodies: the cultural department of the Central Committee, the ideology department of the same committee, etc. For instance, recommendation Nb. 5 says: "Cut out the concept of God"; Nb. 7 says: "Cut out the concept of Christianity"; and Nb. 8 says: "The conference. Cut out the foreign executives." The motive for Gibarian's suicide (not in Lem) ought to be that he is sacrificing himself for his friends and colleagues. Tarkovsky found most of the recommendations absurd. He writes: "I simply cannot work out what they meant, or rather, what was in their minds, when they gave me those corrections." Nb. 21 says: "Put in some quotations from Kolmogorov (about the finite nature of man)." It probably shows that either there was a mathematician in

[9] The joining of like to unlike was at the basis of the philosophies of Heraclitus, Anaximander, and the Pythagoreans.

[10] The passage is also included in the Introduction to his book *Mathematics as metaphor* (Manin 2007).

one of these committees, or that Kolmogorov's theories went deep in the collective body of the society.

Let us return to language.

The question of the relationship between mathematics and language is also addressed in the interview *Good proofs are proofs that make us wiser* (Aign and Schmidt 1998) in which Manin, answering a question about the cultural role of mathematics, sketches a wide historical perspective on language, showing how natural language, used for the purposes of science and the scientific description of nature, became progressively specialized, ending up with the language of mathematics:

> In my opinion, the basis of all human culture is language, and mathematics is a special kind of linguistic activity. Natural language is an extremely flexible tool of communicating essentials required for survival, of expressing one's emotions and enforcing one's will, of creating virtual worlds of poetry and religion, and of seduction and conviction. However, natural language is not very well fit for acquiring, organizing, and keeping our growing understanding of nature, which is the most characteristic trait of the modern civilization. Aristotle was arguably the last great mind that stretched this capability of language to its limits. With the advent of Galileo, Kepler, and Newton, the natural language in sciences was relegated to the role of a high-level mediator between the actual scientific knowledge encoded in astronomical tables, chemical formulas, equations of quantum field theory, databases of human genome on the one hand, and our brains on the other hand. Using the natural language in studying and teaching sciences, we bring with it our values and prejudices, poetical imagery, passion for power, and Trickster's skills, but nothing really essential for the content of the scientific discourse. Everything that is essential is carried out either by long lists of more or less well-structured data, or by mathematics. For this reason, I believe that mathematics is one of the most remarkable achievements of culture, and my lifelong preoccupation with mathematics in the capacity of researcher and teacher still leaves me with awe and admiration by the end of every working day. However, I do not believe that I can convincingly defend this conviction in the context of contemporary public debate on science and human values.

Manin's approach to language and linguistics involves ideas on psycholinguistics, social interactions, self-consciousness, the theory of development of the central nervous system, animal behavior, the human psychopathology of language, and others. I would like to mention here the relationship he makes between, on the one hand, the history of language and, on the other hand, that of the known cultures, from the prehistoric man who painted on cave walls, passing through the Greeks of the time of Homer, mentioning the Winebago Indians, the biblical world, Sanskrit culture, etc. until modern man. This historical parallel, which is part of Manin's aim to understand the process of language, its structural properties, and its evolution, is also an example of the notable analogies that he envisioned, and of which I will say a few more words in what follows.

4 Analogies 1: Cognitive Development, Internet, and Human Condition

An important analogy Manin makes in his theory of language is the comparison between the linguistic development of the child and the history of speech and language. Among the questions he addresses is the following: Since a child can

only learn to speak to the extent that he or she is immersed in a language environment, that is, being in contact with adults who speak with him and with each other, who was then the "adult" for the first men? Among the other problems he points out is the one of "gifted individuals" in the face of language skills: (Manin 2007, p. 171): "[Why,] despite the democratization of education, such national poets as Pushkin and Dante so far exceeded the average level of language abilities as to become the nation's language teachers for centuries? ".

Manin also talked about analogies between the history of languages and that of computers. In the article *Semantic spaces* (Manin and Marcolli 2016) which he wrote with Matilde Marcolli, the two authors discuss mathematical, and in particular geometric, constructions which help bridging, on the one hand, database, usually associated with computer processing and computer memory, and, on the other hand, natural language, which resides in the human brain and functions in human communication. Manin develops an analogous theory in an article titled *Cognitive Networks: Brains, Internet, and Civilizations* he wrote in collaboration with his son Dmitry (Manin and Manin 2017). In the same paper, the cognitive activity of the nervous system is discussed in analogy with the Internet: neurones and neural networks are compared with computers. The two Manins, with the aim of understanding the functioning of the cognitive activities of the brain, explore a comparison between certain neural networks and computers. The whole nervous system is compared with the Internet. Dissociative phenomena like multiple personalities, automatisms, fugues, and hypnosis are also mentioned in this "brain/Internet metaphor." The Saussurean trichotomy langue/langage/parole is involved in this study.[11]

Another analogy of the same kind, between something a priori special and something universal, appears right in the Introduction to his book *Mathematics as metaphor*, and it is about mathematics, presented as "a specimen and a metaphor of the human condition." Here, Manin makes the following comment: "This attitude is not as esoteric as it might sound, if only because through mathematics, as through poetry and philosophy, dozens of generations communicate to each other, often over the heads of their contemporaries, because in each generation the community of mathematicians is small and scattered all over the world."

I will say more on such analogies after a few remarks on computers and on Manin's ideas on history.

[11] The famous linguist Ferdinand de Saussure (1857–1913), considered as the founder of modern linguistics, in his *Cours de linguistique générale*, makes a distinction between the following three notions: *langue*, the result of a social convention transmitted by society to man and for which the latter does not play any important role, *langage*, as the capacity that allows human beings to communicate and interact with each other, and *parole*, as the personal use of language. Note that English makes no difference between "langue" and "langage."

5 Brain, Computers, and the Internet

Manin, in several works, mentions the brain/Internet metaphor regarding information transmission, and he introduces Kolmogorov complexity in this discussion. In his lecture *Kolmogorov complexity as a hidden factor of scientific discourse* (Manin 2012a), he explains the fact that the characteristic features of scientific theories, from epicycles to the standard model of particles, split into two distinct parts: the first one with relatively small Kolmogorov complexity (laws, basic equations, periodic tables, natural selection, etc.) and the second one with indefinitely large Kolmogorov complexity (examples include the initial and boundary conditions, phenotypes, population, etc.). More generally, in his works on this topic, he divided scientific theories into two parts, "Kolmogorov simple" and "Kolmogorov indefinitely complicated."

Manin has always highlighted the fact that computers have a non-negligible impact on pure mathematics, in that they allow us to do experiments. In the interview (Gelfand 2009), he declares that they gave to the ordinary mathematician a unique possibility of "doing large-scale experiments in mental reality." He says that thanks to computers, we are capable of doing things that only mathematicians of the stature of Euler and Gauss were capable of doing without computers. He declares: "By now, what Euler and Gauss could do, any mathematician can do, sitting at his desk. So if he doesn't have the imagination to distinguish some features of this Platonic reality, he can experiment."

In his paper *The early development of speech and consciousness (Phylogeny)*, which we already quoted, Manin states a metaphor which expands the beautiful expression "the smoke of centuries"[12]: "The sharpness of historical vision drops quickly with distance, and the milestones of subjective past conveniently fall on a logarithmic scale." I will talk about some of Manin's ideas on history in the next section.

6 History

Manin's vision on history is exemplified in his article *Time and periodicity from Ptolemy to Shrödinger: Paradigm shifts* vs. *continuity in history of mathematics* (Manin 2019), in which he discusses Kuhn's notion of *paradigm shift* applied to the history of mathematics. His argument involves examples from the ancient laws of planetary motion until those of elementary particle physics. He starts by quoting Thomas Kuhn who, in his influential book on philosophy of science, *The structure of scientific revolutions* (Kuhn 1962), defended the thesis that history of natural sciences can be divided into periods such that the passage between a period and

[12] Manin says that this expression is in Pushkin. Actually, I found it in Walter Scott's *Rob Roy* (1817), and also in a poem by Dovid Knut (1900–1955), a Russian-Jewish emigre of the first generation who published his poems in Paris in the 1920s.

the next one occurs through a revolution, that is, a radical change in the basic assumptions. Manin maintains that Kuhn's theory does not apply to pure mathematics, a domain, he says, which is different from the other sciences. He recalls that mathematics "has a position mediating, or bridging, daily life, common sense, philosophy, and physics." He asserts that only one part of mathematics is sensitive to the so-called revolutions or paradigm shifts, namely the part that is subject to the "reality tests,"[13] whereas the rest of mathematics, which we call "pure mathematics," experiences only a continuous development. He considers that the intergenerational continuity of that field has been neglected by historians. Placing himself from a point of view which is above the vision field of most professional historians of mathematics and science general, he focuses on the example of the mathematical theory of time and of periodicity. To explain what he means, he starts with Ptolemy's dynamical model of the solar system representing the visible motions, a system which involves complex combinations of circles, with epicycles and secondary epicycles. He then continues with the history of the numbers π and e, the appearance of Fourier sums and Fourier integrals, all the way to the attempts to explain the randomness that appears at the electron level by methods of probability, leading directly to the works of Heisenberg, Pauli, and Schrödinger on quantum mechanics, to Feynman integrals, and to the contemporary cosmological models. He declares that at the end, quantum interaction in quantum mechanics is essentially described by Fourier sums, series, and integrals in complex spaces equipped with Hermitian metrics replacing real Euclidean spaces with real metrics; thus, we are back to Euclid and Ptolemy,[14] and Manin's conclusion is that, in some sense, "quantum mechanics is a complexification of Ptolemy's epicycles."

Regarding continuity versus revolution in the history of mathematics, let me also mention a passage from an interview with M. Gelfand which carries the significant title *We do not choose mathematics as our profession, it chooses us* (Gelfand 2009). The passage comes as a response to the question "What will happen [in mathematics] in the next twenty years?". Manin declares:

> I don't foresee any revolutionary changes, because in my view there have been none in the last 300 years. Every time new and powerful intuitions arose, mathematics retained its character, in some strange way. This is also a theme of a lecture, one I've not given. I would like to show the development of the idea of the integers from the most remote times to Kolmogorov complexity, and all this can be done almost without appealing to new mathematics. One and the same idea persists. It changes a bit in one era or another, its verbal casing changes. But all the same it stays completely invariant and so lives on. Nothing is forgotten. And so I don't foresee anything extraordinary.

[13] Manin puts this expression in quotation marks, and it is not clear whether he intends the literal or the Freudian meaning of this expression; both may fit here (although, from what I know, Manin was not a strong supporter of Freud, maybe because of Freud's materialistic side).

[14] The first terms $\sum_{n=1}^{N} a_n e^{inx}$ of the Fourier series is a trigonometric polynomial which can be put in parallel with Ptolemy's superposition of periodic motions.

7 Analogies 2: Man and Cosmos

A brilliant element of Manin's argument in the paper *Time and periodicity from Ptolemy to Shrödinger: Paradigm shifts* vs. *continuity in history of mathematics* I just discussed involves a comparison between the evolution of knowledge on the scale of civilizations and on that of the development of cognition in the individual brain of a growing human being. This is part of the general pattern he expanded in several works, some of which I alluded to in Sect. 4 making parallels between historical developments, on the one hand, at the civilizational level, and, on the other hand, at the human level.

All these analogies remind me of a general metaphor relating the "cosmos" (or "macrocosmos") and the "microcosmos," which goes back to Ancient Greece (Anaximander, Plato, the Stoics, etc.), which was taken up by early Christian writers, according to which man is presented as a "microcosm" recapitulating in him the whole of "macrocosm."[15] Manin strongly felt this relation, as an analogy between the microcosmos and the macrocosmos. I think that this is an aspect of his thought which has never been emphasized, if ever it was noted. This reminds me of cosmism, a philosophical, scientific, literary, spiritual, and intellectual movement which was born in Russia in the nineteenth century and which attained its apogee at the beginning of the twentieth century. This movement claims an alliance, solidarity, and harmony between man and the whole creation.[16] Manin's ideas have a taste of cosmism even if they stay at the level of *metaphor*, or *theory*.[17] And if one does not like the term cosmism in Manin's work, one can talk at least about cosmology, as in the paper *Time and Periodicity from Ptolemy to Schrödinger* (Manin 2019) which I already mentioned. I also would like to mention here his talk at the 2014 Plenary Session of the Pontifical Academy of Sciences, titled *Big Bang, Blow Up, and Modular Curves: Algebraic Geometry in Cosmology* (Manin 2014),[18] in which he starts by quoting T. S. Eliot, "In my beginning is my end," and where he sets his goal as follows: "We are trying to explain how it could be that in my end (that is, in the universe's end) is my (that is, the universe's) beginning." Again, the analogy – here an identification – between man and the universe. Let me also quote another Russian

[15] To quote again Russian authors, I mention Sergei Bulgakov, who writes that man is a "microcosm, and his imprint therefore lies upon the entire world, the macrocosm," and that "by his body man belongs to the creaturely world, which, he, as microcosm, has in himself and unifies and generalizes," (Bulgakov 2008, pp. 173, 279), etc.

[16] The founder of cosmism is considered to be Nikolaï Fiodorov (1829–1903). The movement was developed especially in the first three decades of the twentieth century, before it was squashed brutally by Stalin. This movement inspired writers, philosophers, composers, theater directors, and artists, like Leo Tolstoi, Alexander Scriabin, Vassily Kandinsky, Casimir Malevic, Vladimir Soloviev, and Sergei Bulgakov.

[17] The word *theory* comes from the Greek word "theōria," which means "contemplation."

[18] The article is a joint work with Matilde Marcolli.

author, on the same topic, Pavel Florensky,[19] from his booklet *Hamlet* (Florensky 2006, pp. 24–25), talking about "development" as a result of either universal and supraindividual human reason, or of the individual human reason, which he calls "microcosm":

> [. . .] Motion and development come either from the universal, supra-individual human reason, or from the common, individual human reason. The latter is more easily observable given its reduced dimensions, and its more or less conscious construction, it is a microcosm. Nevertheless, the microcosm corresponds to the macrocosm, in this case the natural, spontaneous and irresistible dialectics of the universal human consciousness; there is a reciprocal correspondence between phylogeny and ontology, between the philosophical structure of the individual and the historical destinies of the world consciousness.

To return to Tarkovsky's universe, I would like to mention this scene from the *Sacrifice* in which the character, in the middle of a nuclear accident, knowing that he is ready to perish, instead of making, as one would expect, an evaluation of his life, makes an evaluation of existence in general. He strives for salvation in many forms, frightened by an eschatological feeling. He seeks help, but finds none, and is finally seized by this destructive eschatological feeling, not only for himself after his death, but also for the universe after its disappearance. I can also quote Andrei Tarkovsky again, from his book *Captured time* (Tarkovsky 2004): "There must be other possibilities of working with sound, which would allow us to be more precise, more faithful to the inner world that we try to recreate on the screen, and not only to the inner world of the artist but to what is inside the world itself, to what is essential to it and independent of us." Again a relation between the inner world of man and the world itself. Finally, I can quote a line from Arseni Tarkovsky's poem *Life, life* (1965): ". . . I tailored the age to fit me . . .."

In think that this feeling of the cosmos and of a strong bond between man and the universe, exemplified in Manin's writings, is a common feature of all Russian thought.

8 Proof and Truth, Mathematics and Tarkovsky Again

This section consists essentially of five quotes: two by Manin and three by Tarkovsky.

All of us have read (or heard of) Bourbaki's famous sentence, from the introduction to *Set Theory*, the opening treatise of the *Elements*: "Depuis les Grecs, qui dit

[19] The mathematician, theologian, physicist, philosopher, and historian of art Pavel Florensky (1882–1937) was dubbed the "Russian Leonardo" and the "Pascal of the Gulag." Solzhenitsyn said about him that he was "perhaps the most remarkable person devoured by the Gulag." The translation of his books and articles in French, English, Romanian, and other languages have taken an accelerated pace in the last two decades. I wrote an article on him for the present Handbook (Papadopoulos 2023).

mathématiques dit démonstration."[20] Manin belongs to those who go against the grain. In his Kyoto ICM talk, *Mathematics as metaphor* (Manin 1990), he writes:

> [. . .] What is relevant is the imbalance between various basic values which is produced by the emphasis on proof. Proof itself is a deviate of the notion of 'truth'. There are a lot of values beside truth, among them 'activities', 'beauty' and 'understanding', which are essential in high school teaching and later. Neglecting precisely these values, a teacher (or a university professor) tragically fails.

Let me complement this discussion about "truth" by some words of Tarkovsky, whose name I associate with that of Manin for reasons I explained at the beginning of my article. This is a quote, again from Tarkovsky's diary, in which he talks at the same time of truth, the cosmos, Euclid, and the infinite, topics which were all dear to Manin. He writes, on September 5, 1970:

> [. . .] Since [truth] is human, it is limited, rigidly confined, in human terms, within the framework of the human milieu. There is no conceivable link between what is human and the cosmos. And the same applies to truth. To attain greatness within our own limits—which are Euclidean and insignificant in juxtaposition with infinite—is to illustrate that we are merely human."

In the next section, I will say a few words about Manin as an artist, and in a later section I will quote one of his poems. Let me, before that, quote a passage, written in Manin's poetical style, about proof, as a conclusion of his paper *Foundations as superstructure* (Manin 2012b):

> One metaphor of proof is a route, which might be a desert track boring and unimpressive until one finally reaches the oasis of one's destination, or a foot path in green hills, exciting and energizing, opening great vistas of unexplored lands and seductive offshoots, leading far away even after the initial destination point has been reached.

Finally, let me conclude this section with two quotes on mathematics from Tarkovsky's *Diary.* On March 24, 1982, he writes:

> What is expressed in mathematics is not so much objective laws of the world as laws of the human psyche, laws of logic, of the human mind. It's really a kind of mental game, and yet the exact sciences, as they are called, command extraordinary respect—physics, astronomy, and so on. It's very odd, in fact I would say an amazing, paradoxical misconception.

On April 2 of the same year, he writes:

> Our reason cannot reach the other parameters or other dimensions which exist, and so it fantasizes about them in the form of mathematics and physics. Science involves the discovery not so much of objective laws of nature, as of the laws which govern the

[20] Since the Greeks, talking about mathematics means proving.

> functioning of our consciousness. A kind of music; image; symbol; sign. A mathematical symbol of truth, corresponding to our capacity for knowing it with our brains.

I am always surprised to see how much the filmmaker understood what mathematics is about, even though he never studied mathematics.

9 Painting, the Brain, and Reverse Perspective

I would like to mention an episode on painting recounted in the French version of Manin's book, published in 2021 (Manin 2007, pp. 426–427).[21] He talks there about a man whose full name he does not give, referring to him only by his initials, YM. In fact, before I read this text of Manin, I had already heard this story from him, as something that happened to him personally. In the book, the episode is part of a discussion regarding the asymmetry of the human brain, the tensions between its two hemispheres, and the main features of the division of its cognitive functions. The story is the following.

In 1973, Manin, 36 years old, who was already a professor at the Lomonosov State University in Moscow, was suddenly affected by a brain disease called *arachnoïdite*, an inflammation of the arachnoid – one of three membranes that surround and protect the spinal cord. This disease causes neurological disorders, and sometimes it attacks the back and the limbs. In Manin's case, the sickness was probably a result of a poorly treated flu. As a consequence, he underwent a treatment with antibiotics that lasted several months. He was not able to do mathematics anymore. One day, in the fourth month of his illness, while riding the subway home on the outskirts of Moscow, he felt a sudden urge to paint, although he had never painted before. He got off at the train stop, took the metro in the backwards direction, that is, toward the city center, and there he stopped at an artists' materials store. He bought brushes, tubes of oil paint, and blank canvases. Back home, he started to paint. For several months, painting became an important activity in his life, perhaps the only original activity. In the book (Manin 2007) (p. 427 of the French version), Manin lists a number of canvases he painted during that period.

In retrospect, after he had returned to normal activity, and after he had stopped drawing and painting, Manin examined his paintings, trying to understand the states through which he passed. Some of his drawings seemed strange to him, until he understood that they satisfy a theory developed by a specialist in functional cerebral asymmetry who works at the Institute of Biochemistry and Evolutionary Physiology of the Russian Academy of Sciences. This theory is reported on in an article on artistic activity and cerebral asymmetry (Nikolaenko 2003). The research is based on clinical observations of drawings made by patients with brain damage. The conclusion of this study is that someone who makes drawings and who is in the state in

[21] The episode is told in a chapter titled *Spontaneous Artistic Activity, Origin of logograms, and Mathematical Intuition*. This chapter is not contained in the English version of the book.

which Manin was during his illness – a state where the right hemisphere of his brain (or his "right brain") is predominant – tends to produce images that seem too close to the person looking at them, and this is why they are drawn in reverse perspective. In contrast, the left hemisphere, which (for the majority of human beings) is the verbal and logical hemisphere, tends to produce representations of space with the standard proportion scheme and with an ordinary perspective. The above story, which describes Manin's personal experience, is an illustration of this fact.

Manin explains at the beginning of his article that the asymmetry between the left and right hemispheres of the brain is not only a functional division, but the source of a dynamic competition between the two hemispheres which, when it occurs, leads to a back and forth motion around a certain balance of the brain. The point of his article is to say (again) that such an equilibrium can also be observed in the study of civilizations and their cultures, especially in periods of transition. He discusses the balance of the brain in the context of the origin of writing, its development and its transmission at the level of the cultural human heritage, and also in connection with the drawings that survive on the prehistoric caves in the South of France, representing animals and hunting scenes, compared to other forms of realistic representations, talking also about poetry, etc. At the same time, he addresses the case of history of mathematics, noting in particular the tension, in Euclid's *Elements*, between the use of the natural language to express the *logic* of the proofs, and that of the figures, which express the underlying *imagination*.

Returning to Manin's drawing experience, let me say that personally, I sometimes had to deal with colleagues who, while we were discussing in front of the blackboard, used to draw awkward pictures; for instance I noticed that some of them, when they draw a cube the perspective is always reversed, and I always wondered how that could be. I understood much later, when I read Manin's explanations on the brain and reverse perspective, that what I experienced was something that could be explained, and the drawing, here, is a tool that helps us exploring the neural mechanisms that are at the base of the aesthetic experience of the person who performed it.

There are other explanations. The manner we draw, in reverse or in Renaissance (call it "usual") perspective, is also a question of how we perceive the world, and I cannot help but mention here Byzantine iconography, of which Russian iconography is the full heir, whereby the drawing is usually done in reverse perspective. In this connection, I would like to quote again Pavel Florensky, from his essay *Reverse Perspective* (1920) (Florensky 2002, p. 219):

> The drawings of children, in their lack of perspective and especially their use of reverse perspective, vividly recall mediaeval drawings, despite the efforts of educators to instill in children the laws of linear perspective. It is only when they lose their spontaneous relationship to the world that children lose reverse perspective and submit to the schema with which they have been indoctrinated. This is how all children behave, independent of each other. This means that it is not mere chance, or a willful invention by one of them putting on Byzantine airs, but a representational method that derives from a characteristic perceptual synthesis of the world. Since the way children think is not weak thinking but a particular type of thinking which, moreover, is capable of unlimited degrees of perfection, including genius, and indeed is primarily akin to genius, it must be admitted that the use of reverse perspective

> to depict the world is also far from being an unsuccessful, ill-understood, imperfectly learned linear perspective, and is rather a distinctive grasp of the world that should be reckoned with as a mature and independent representational method.

After he recovered his original functioning of the brain, Manin stopped painting, and he came back to mathematics. He did not stop being an artist; mathematics was also, for him, an art. In his reception speech as foreign associate to the Paris Academy of Sciences (Manin 2006), he tells how he came back later to mathematical research, and in particular to his favorite field, algebraic geometry. About this field, he writes that he sees the set of solutions of systems of polynomial equations with several variables – an object that is at the heart of algebraic geometry – as "a geometric entity, a shape situated in a multidimensional space, stretching to infinity along some directions and capriciously closing upon itself at others. Variety and complexity of such forms is infinitely richer than anything one could glimpse at modern exhibitions of abstract art, but algebraic geometers managed to find patterns, discover connections and laws of this immense world."

Manin also talks about mathematics as an art while he gives his point of view on the heritage of Georg Cantor (another Russian-born mathematician). He writes, at the beginning of the paper (Manin 2004): "Georg Cantor's grand meta-narrative, Set Theory, created by him almost singlehandedly in the span of about fifteen years, resembles a piece of high art more than a scientific theory."

Let me also mention a passage in the interview (Gelfand 2009): "Once I was asked to deliver a lecture for the general public in an art museum, and I decided that the Banach–Tarski paradox is a great subject for the presentation *The Abstract Art of Mathematics*."

Let me mention, to close this subject, that on the dust cover of Manin's *Mathematics as metaphor*, published by the AMS, there is a picture of a house, with the inscription *Geomêtre* over the entrance door; the house is drawn in reverse perspective. I never asked him an explanation.

From visual art and abstract art, let us pass to poetry.

10 A Poem

Manin, in an article he wrote on Georg Cantor (Manin 2004), has, as an epigraph, the following citation from V. Tasić's (2001): "God is no geometer, rather an unpredictable poet."

Like God, Manin was a poet. In the French version of *Mathematics as metaphor* (Manin 2007, p. 536),[22] he wrote a poem related to his painting period. The title of the poem is *Je peins à l'huile*. I reproduce it here, in French:

[22] Manin was very happy of the fact that the French version of the book, which appeared in 2022, included the poems. The French translation of his book was done by Claire Vajou, but it is certain that the translation of his poems was done with his close collaboration, maybe by him alone (he was completely fluent in French).

La touche vient toucher la touche
comme la phalène — la page.
La touche vient toucher la touche
comme le canon glissant — la tempe.
La touche vient toucher la touche.
Le cerveau se languit sans langue.
L'hémisphère taiseux travaille
comme fait une avalanche —
le bruit arrive en retard . . .

It would be a redundancy to say that Manin was permanently reading poetry. We once talked about the Greek poet Constantine Cavafy, and he told me he has his works on his shelf, in several editions.

11 Platonism

We talked about mathematics as a language, but mathematics is also ideas, and Manin had his own idea about ideas. Let us hear again what he says, in his Reception speech at the Paris Academy of Sciences (Manin 2006):[23]

> [. . .] This Platonic feeling that even most abstruse mathematical ideas are somehow predestined to be in harmony with the physical world, always constituted for me one of the most irresistible attractions of our trade. Stéphane Mallarmé wanted to make us aware that poetry is made of words rather than ideas. To a certain degree, this is true about mathematics as well, but in a more profound sense, this is fundamentally wrong. (I suspect that this is wrong for poetry as well).

At several occasions, Manin expressed his "Platonic feeling" of preexisting mathematical notions. In the interview *Good proofs are proofs that make us wiser* (Aign and Schmidt 1998), he declares:

> I see the process of mathematical creation as a kind of recognizing a preexisting pattern. When you study something—topology, probability, number theory, whatever—first you acquire a general vision of the vast territory, then you focus on a part of it. Later you try to recognize "what is there?" and "what has already been seen by other people?". So you can read other papers and finally start discerning something nobody has seen before you.

In his interview with Gelfand (2009), he expresses the same idea, slightly differently:

> I must explain to you how I imagine mathematics. I am an emotional Platonist (not a rational one: there are no rational arguments in favor of Platonism). Somehow or other, for me mathematical research is a discovery, not an invention. I imagine for myself a great castle, or something like that, and you gradually start seeing its contours through the deep mist, and begin to investigate something. How you formulate what it is you've seen depends on your type of thinking and on the scale of what you have seen, and on the social circumstances around you, and so on.

[23] The passage is also reproduced in the Introduction of *Mathematics as metaphor* (Manin 2007).

Staying with Plato, let me mention Manin's book with I. Yu. Kobzarev, *Elementary Particles: Mathematics, Physics and Philosophy* (Kobzarev and Manin 1989), a philosophical dialogue, formally written in the style of Plato's dialogues. There are three characters: a theoretical physicist, an experimental physicist, and a philosopher, and the aim of the dialogue is to present the development of elementary particle physics, including its present state. However, unlike in Plato's dialogues, there is no "wise man" involved in this dialogue; such a figure is replaced by that of a scientist. Let me take this opportunity to quote Manin again, from *Mathematics as metaphor* (p. 197):

> The central figure of a philosophic dialogue is a wise man, whereas modernity generally and systematically replaces wisdom by training. Wisdom seems to be an inborn faculty slowly ripened by life experience; as such it is rarely met and even more rarely put to any use. Training is a democratic surrogate for wisdom which, in spite of all of its (mainly aesthetic) drawbacks, is superior in one respect: it produces professionals.

Let me also mention, since we are talking about Platonism, that the adjective "Platonic," which is systematically used in such a context (the mathematician discovering preexistent objects) indeed is part of Plato's teaching.[24] The term "Platonic" is nevertheless abusive, because the fact referred to is not sufficient to characterize Plato's view on mathematical objects.[25] In fact, Plato was absolutely against the idea that mathematical objects may be used to describe the real world: They can only describe immutable things, whereas the real world is permanently subject to movement and change. In contrast, Manin has always been interested in mathematics as a means of describing reality. Even in his work on algebraic geometry or number theory, he was resolute in thinking in terms of applications to theoretical thinking. Besides that, he taught us that mathematics is not only the language of nature, but it is also an adequate language for talking about art, literature, and the deep human psyche. More lyrically, he writes that mathematics is a "novel about Nature and Humankind" and he adds that his wish is "to restore a certain balance between the technological and the humanitarian sides of mathematics" (Manin 2007, p. 28).

[24] The idea that abstract mathematical objects exist independently of us and our knowledge of them is one of the basic teachings of Plato, who also considered that knowledge (which, for him, is, to a large extent, mathematical), is simply recollection (*anamnesis*) of innate knowledge, about preexisting things. The standard reference for this theory of *anamnesis* is Plato's *Meno* 81e1–82b8. It is worth noting that in this passage, Plato, to illustrate his idea, brings in Socrates helping a slave boy recollecting a specific knowledge, which, in fact, is a mathematical knowledge: how to construct a square whose area is twice that of another given square. S. Negrepontis explained to me that the method Socrates uses for this recollection turns out to be anthyphaeretic division. Finally, let me recall that "Platonism," as a belief in preexisiting objects (outside our thought), is contrary to the intuitionistic trend in mathematics (mostly represented, in the modern period, by Brouwer), which holds that mathematical objects exist only when we can construct them.

[25] As Plotnitsky rightly points out in his essay *Continuity and discontinuity in, and between, mathematics and physics* (Plotnitsky 2023): "mathematical Platonism (which is a twentieth-century conception) should not be confused with Plato's own philosophy." In fact, the term "Platonic" is often used and misused. A Japanese friend told me that in Japan, this word is used exclusively (as a Japanese word) as an adjective for a love relation, to say that it is purely mental.

It has often been said (by mathematicians) that there are two kinds of mathematicians: those who build theories and those who solve problems. If this is true, then what we recalled in this article says that Manin belongs definitely to the first category. But I think that this distinction is rather secondary, and even irrelevant, in Manin's case. For him, mathematics was a language, and he was interested in language much more than in mathematics. According to Aristotle, language is what distinguishes man from the rest of the animals, as we have been reminded above. I would like to quote, closer to us, Emmanuel Levinas: "[. . .] l'Infini se passe dans le Dire [. . .]."[26]

I started this chapter with a personal recollection, and I will also finish it with a personal recollection.

12 In Guise of a Conclusion

While I was writing this chapter, I often regretted not having had more conversations with Manin about all of this. In one of our last contacts, an email dated September 14, 2022, answering an invitation I made for him and Xenia to visit us in Strasbourg, he wrote me that he was tired and that he did not travel anymore. I regret not having had the reflex to tell him: "In this case I will come to see you in Bonn."

Abstract

A traditional question in the philosophy of mathematics is to give an answer to the question: What is the nature of mathematical objects? This chapter considers the main answers that have been given to this question, specifically those according to which mathematical objects are independently existing entities, or abstractions, or logical objects, or simplifications, or mental constructions, or structures, or fictions, or idealizations of sensible things, or idealizations of operations. The

1 Introduction

A traditional question in the philosophy of mathematics is to give an answer to the question: What is the nature of mathematical objects?

This question originated in antiquity. Herodotus says that Egypt's king Sesostris (twentieth century BCE) "made a division of the soil of Egypt among the inhabitants, assigning square parcels of land of equal size to all, and obtaining his chief revenue from the rent which the holders were required to pay him year by year" (Herodotus, *Historiae*, II, 109.7–10). If any man was robbed of a part of his land by the inundations of the Nile, "he would come to the king and tell him what had happened; then the king would send inspectors to measure how much land he had lost, so that thereafter it should pay in proportion to the tax originally imposed. Thus discovered" in Egypt, "geometry then passed into Greece" (ibid., II, 109.11–14).

Passing into Greece, however, mathematics changed nature, it became an abstract discipline, detached from its empirical origin. Specifically, "Pythagoras transformed the study of geometry into a liberal discipline, tracing its first principles and studying its problems from a purely abstract and theoretical viewpoint" (Proclus, *In primum Euclidis Elementorum librum commentarii*, 65.15–19).

The change in nature of mathematics, in particular, concerned mathematical objects. Because of its concrete nature, Egyptian mathematics was about such things as parcels of land, thus about physical things, knowable by the senses. Conversely, because of its abstract nature, Greek mathematics was about non-physical things, not knowable by the senses.

Plato assumed that these non-physical things were things existing independently of the mind, which could be known only by intuition.

Indeed, Plato says that, although mathematicians "use visible figures and make their claims about them," they "are not thinking of them but of those ideas of which they are likeness. They pursue their inquiry for the sake of the square itself and the diagonal itself, and not for the sake of the diagonal they draw, and similarly with the others" (Plato, *Respublica*, VI, 510 d 5–e 1). Mathematicians use the visible figures they draw "only as images, but what they really seek is to get sight of those ideas, which can be seen only by the mind" (ibid., VI, 510 e 3–511 a 1). In fact, "there

really exist these ideas in themselves, that we cannot perceive with the senses but only with intuition" (Plato, *Timaeus*, 51 d 4–5). They have a kind of reality that "is always the same, ungenerated and imperishable," it "is not visible nor perceptible by any sense," and is such that "only intuition has been granted to contemplate it" (ibid., 52 a 1–4).

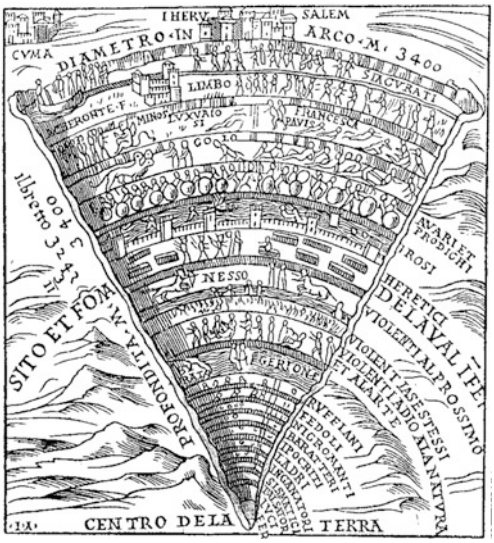
Since antiquity, the question "What is the nature of mathematical objects?" has received several answers. This chapter discusses the main ones and shows their shortcomings. Then, it considers an alternative answer, according to which mathematical objects are hypotheses introduced to solve mathematical problems by the analytic method.

2 Mathematical Objects As Independently Existing Entities

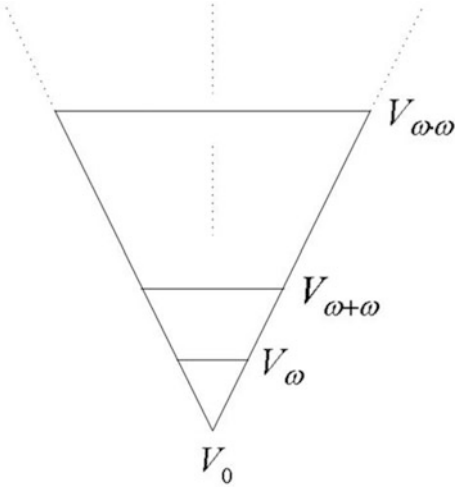
An answer to the question "What is the nature of mathematical objects?" is that they are independently existing entities. As we have just seen, this conception of mathematical objects has been first formulated by Plato, therefore it goes under the name "mathematical platonism," which was coined by Bernays (1935). Such conception has a large following between mathematicians because, as Dieudonné says, "each mathematician" has "the feeling" that "he is working with something real," namely, with independently existing entities, and this feeling "is very convenient" (Dieudonné 1970, 145).

Although the conception that mathematical objects are independently existing entities has been first formulated by Plato, it, however, is best known in Gödel's formulation.

Gödel says that mathematics "describes a non-sensual reality, which exists independently both of the acts and of the dispositions of the human mind and is only perceived, and probably perceived very incompletely, by the human mind" (Gödel 1986–2002, III, 323). Such non-sensual reality consists of sets, and precisely of "the objects of transfinite set theory" (ibid., II, 267). These objects do "not belong to the physical world," and "even their indirect connection with physical experience is very loose" (ibid.). They "exist objectively and independently of our mental acts and decisions" (ibid., III, 311). A set can be conceived as "something obtainable from" the empty set $\varnothing$ "by iterated application of the operation 'set of'," where iterated application "is meant to include transfinite iteration" (ibid., II, 259 and footnote 13). If by the operation 'set of' it is meant the power set operation $\mathrm{P}(X)$ that collects all the subsets of a set X into one set, then a set can be conceived as a member of the hierarchy defined by: $V_0 = \varnothing$; (ii) $V_{\alpha+1} = \mathrm{P}(V_\alpha)$ for any ordinal α; (iii) $V_\lambda = \bigcup_{\alpha<\lambda} V_\alpha$, for any limit ordinal λ. Such hierarchy is commonly represented in a way that is reminiscent of the current representations of Dante's *Inferno*.



For, it is represented as follows.



But, "despite their remoteness from sense experience, we do have something like a perception also of the objects of set theory," namely, "mathematical intuition" (ibid., II, 268). This is a superior faculty, which is not "derived from subconscious induction or Darwinian adaptation" (ibid., III, 354).

Mathematical intuition "is sufficiently clear to produce the axioms of set theory and an open series of extensions of them" (ibid., II, 268). It gives insights both "for obtaining unambiguous answers to the questions of transfinite set theory," such as

Cantor's continuum hypothesis, and "for the solution of the problems of finitary number theory (of the type of Godlbach's conjecture)" (ibid., II, 269).

Through mathematical intuition, sets "are known precisely, and general laws" about them "can be recognized with certainty," because they can be derived from axioms "by deductive, not inductive, inference" (ibid., III, 312, footnote 18). So, one can recognize "the truth of the axioms concerning them" (ibid., II, 258). In fact, for the "axioms there exists no other" rational "foundation except that they" can "directly be perceived to be true" by "an intuition of the objects falling under them" (ibid., III, 346–347).

We can arrive at directly perceiving the axioms to be true by the procedure which "consists in focusing more sharply on the concepts concerned" (ibid., III, 383). Indeed, "by directing our attention in a certain way," we will get an intuition of those concepts, and hence a "comprehensive and secure insight" into "the axioms that hold for them" (ibid.). In fact, "cultivating (deepening) knowledge of the abstract concepts" will "produce in us a new state of consciousness in which we describe in detail the basic concepts we use in our thought" (ibid.).

However, besides mathematical intuition, there is "another (though only probable) criterion of truth of mathematical axioms, namely their fruitfulness in mathematics and, one may add, possibly also in physics" (ibid., II, 269). "Fruitfulness" means "fruitfulness in consequences, in particular in 'verifiable' consequences, i.e., consequences demonstrable without the new axiom" (ibid., II, 261). The "simplest case of an application of the criterion under discussion arises when some set-theoretical axiom has number-theoretical consequences verifiable by computation up to any given integer" (ibid.).

The conception that mathematical objects are independently existing entities, however, has the following shortcomings.

1. Gödel claims that mathematics describes a non-sensual reality, which exists independently both of the acts and of the dispositions of the human mind. This raises the question: How, then, can mathematics be useful in physics? Gödel answers this question saying that mathematics "might help us considerably in knowing" the physical reality "if in some respect, or as to certain parts, it happened to be similar or isomorphic to it. In fact this would correspond closely to the manner in which mathematics is applied in theoretical physics" (Gödel 1986–2002, III, 353–354, footnote 44). Thus, according to Gödel, mathematics can be useful in physics if it is isomorphic to the physical reality. But this conflicts with the fact that different mathematical theories are commonly used to deal with the same physical phenomena. For example, on the one hand, Weyl says that group theory is exactly what is "necessary for an adequate description of the quantum mechanical relations" (Weyl 1950, xxi). On the other hand, von Neumann says that Hilbert space theory is exactly what is necessary for an adequate description of the quantum mechanical relations, because it permits to present "quantum mechanics in a unified representation" which "is mathematically rigorous" (von Neumann 1955, vii). Now, group theory and Hilbert space theory cannot be both isomorphic to the physical reality.

2. Gödel claims that, despite their remoteness from sense experience, we do have something like a perception also of the objects of set theory, namely, mathematical intuition. This raises the question: How can we have this kind of perception? Gödel assumes that, in order "to make the handling of abstract impressions (as opposed to sense impressions) possible," there must be "some physical organ," and that "such a physical organ must be closely related to the neural center for language" (Wang 1996, 233). But there is no evidence that such a physical organ exists, and indeed its existence makes no sense in evolutionary terms, because the highly abstract objects of set theory were introduced only in the nineteenth century. As to the claim that such a physical organ must be closely related to the neural center for language, experiments have shown that "mathematics and language are functionally and neuroanatomically independent" (Brannon 2005, 3178).
3. Gödel claims that mathematical intuition is sufficiently clear to produce the axioms of set theory and an open series of extensions of them. But this conflicts with the fact that, at least since Kant, it has been held that "an intuition is a singular representation" (Kant 1992, 589). How, then, can mathematical intuition produce the axioms of set theory and an open series of extensions of them, since the axioms in question are not singular propositions but universal propositions? Moreover, mathematical intuition has given no insight for obtaining unambiguous answers to the questions of transfinite set theory, such as Cantor's continuum hypothesis, and for the solution of the problems of finitary number theory, of the type of Godlbach's conjecture. These problems remain unsolved.
4. Gödel claims that, through mathematical intuition, sets are known precisely, and general laws about them can be recognized with certainty, because they can be derived from axioms by deductive inference. But this conflicts with Gödel's second incompleteness theorem, by which the consistency of no axiom system for set theory can be recognized with certainty. Therefore, one cannot say that, by mathematical intuition, sets are known precisely, and general laws about them can be recognized with certainty because they can be derived from axioms by deductive inference. For, intuition is unreliable, so it is unrealistic to use it as a foundation for the axioms of sets theory and the whole of mathematics.
5. Gödel claims that we can arrive at directly perceiving the axioms to be true by the procedure which consists in focusing more sharply on the concepts concerned. But this is untenable. For, suppose that, by focusing more sharply on the concept of set Σ, we get an intuition of that concept. Let S be a formal system for set theory whose axioms this intuition ensures us to be true of Σ. Thus, Σ is a model of S, hence S is consistent. Then, however, by Gödel's first incompleteness theorem, there is a sentence A of S which is true of Σ but is unprovable in S. Since A is unprovable in S, the formal system $S' = S \cup \{\neg A\}$ is consistent, and hence has a model, say Σ'. Then $\neg A$ is true of Σ' and hence A is false of Σ'. Thus, Σ and $\Sigma'$are both models of S, but A is true of Σ and false of Σ', so Σ and Σ' are not equivalent.

Suppose now that, once again, as Gödel says, by focusing more sharply on the concept of set Σ', we get an intuition of that concept. Then we have two different intuitions, one ensuring us that Σ is the concept of set, and the other one ensuring us that Σ' is the concept of set, where the sentence A is true of Σ and false of Σ'. Which of Σ and Σ' is the genuine concept of set? Gödel's procedure provides no answer, so through it we cannot arrive at directly perceiving which axioms for sets are true.

6. Gödel claims that, besides mathematical intuition, there is another (though only probable) criterion of truth of mathematical axioms, namely, their fruitfulness in consequences, and that the simplest case of application of this criterion of truth is when some set-theoretical axiom has number-theoretical consequences verifiable by computation up to any given integer. But this is untenable. As Gödel himself admits, this criterion of truth "cannot yet be applied to the specifically set-theoretic axioms (such as those referring to great cardinal numbers), because very little is known about their consequences in other fields" (Gödel 1986–2002, II, 269). What is more important, the criterion of truth in question fails because from false axioms it is possible to deduce true consequences. In order to assert that the axioms are true, it should be possible to demonstrate that all the consequences deducible from them are true, but this is generally impossible. This is already made clear by Kant, who says that "inferring the truth of a cognition from the truth of its consequences, would be allowed only if all of the possible consequences are true," but "this procedure is unusable, because to have insight into all possible consequences of any proposition that is assumed exceeds our powers" (Kant 1998, A790/B818). Evidence for Kant's statement is provided by the fact that the set of all consequences of the axioms of second-order Peano arithmetic PA^2 is not algorithmically enumerable. For, assume P: The set of all consequences of the axioms of PA^2 is algorithmically enumerable. Now, since the axioms of PA^2 are categorical, a second-order sentence is a consequence of the axioms of PA^2 if and only if it is true of the natural numbers. From this, by the assumption P, it follows Q: The set of all second-order sentences true of the natural numbers is algorithmically enumerable. But, by Tarski's theorem for second-order sentences, the set of all second-order sentences true of the natural numbers is not definable in the set of all-natural numbers by any second-order formula, and hence *a fortiori* is not algorithmically enumerable. Thus not-Q: The set of all second-order sentences true of the natural numbers is not algorithmically enumerable. So, from the assumption P, we have deduced a contradiction, Q and not-Q. Therefore, by *reductio ad absurdum*, we conclude not-P: The set of all consequences of the axioms of PA^2 is not algorithmically enumerable. This means that there exists no algorithm, *a fortiori* no feasible procedure, for enumerating all consequences of the axioms of PA^2. So, as Kant says, inferring the truth of a cognition from the truth of its consequences is unfeasible, because it exceeds our powers.

3 Mathematical Objects as Abstractions

Another answer to the question "What is the nature of mathematical objects?" is that they are objects obtained by abstraction from sensible things, where abstraction is the process by which one considers certain attributes of sensible things and leaves out the other ones. Therefore, objects obtained by abstraction from sensible things have attributes which also occur in sensible things. This conception of mathematical objects has been put forward by Aristotle.

Indeed, Aristotle says that "the mathematician carries out his investigation about things reached by abstraction. For, he investigates things leaving out all sensible qualities, such as weight, lightness, hardness," and "considering only quantity and continuity, in one, two or three dimensions, and the properties of these as quantitative and continuous; and he does not consider them in any other respect" (Aristotle, *Metaphysica*, K 3, 1061 a 28–35).

Thus, the mathematician investigates the same things as the physicist, because "the physicist concerns himself with all the properties, active and passive, of physical bodies" (Aristotle, *De Anima*, A 1, 403 b 11–12). And "physical bodies contain surfaces and volumes, lines and points, and these are the subject-matter of mathematics" (Aristotele, *Physica*, B 2, 193 b 24–26).

However "the mathematician, though he too treats of these things, nevertheless does not treat them as the limits of a physical body; nor does he consider the attributes indicated as the attributes of such bodies," but he "separates them" from physical bodies; for, "in thought they are separable from physical motion" (ibid., B 2, 193 b 33–34). That is, the mathematician "thinks of mathematical objects, which are not separate, as being separate, when he thinks of them" (Aristotle, *De Anima*, Γ 7, 431 b 15–16). Thus, the mathematician deals with attributes which "are not considered as properties of any particular physical body and are obtained by abstraction" (Aristotle, *De Anima*, A 1, 403 b 14–15).

On the other hand, "since, as it appears, there is nothing that exists as separate from the sensible magnitudes, it is in the sensible forms that one finds" both the things "that are spoken of in abstraction," that is, the mathematical objects, and "the properties and affections of sensible objects. For this reason, one would not be able to learn or understand anything if he had not the faculty of perception" (ibid., Γ 8, 432 a 3–8). So, although "one thinks of mathematical objects as separate, when one thinks of them," nevertheless they "are not separate" (ibid., Γ 7, 431 b 15–17).

The conception that mathematical objects are abstractions from sensible things, however, has the following shortcomings.

1. By abstraction from sensible things we cannot obtain things which do not exist in sensible things, for example, actual infinite sets. For, as Kant says, "abstraction is only the negative condition under which universal representations can be generated" (Kant 1992, 593). Through it, "nothing is produced, but rather left out" (ibid., 487). Therefore, "abstraction does not add anything," but "rather cuts off everything that does not belong to the concept" (ibid., 351).

2. By abstraction from sensible things we cannot obtain objects having that exactness which is proper to mathematical objects. For example, from an edge of a table, we cannot obtain a straight line, but only a line which is slightly zigzag and with some, however small, breadth.
3. By abstraction from sensible things we cannot obtain objects having that determinateness which is proper to mathematical objects. As Frege says, "suppose, e.g., that there are a black and a white cat sitting side by side before us. We do not attend to their colour, and they become colourless – but they still sit side by side. We do not attend to their posture, and they cease to sit without, however, assuming a different posture – but each of them is still in its place. We no longer attend to the place, and they cease to occupy one – but they continue presumably to be separate" (Frege 1984, 197–198). By these successive abstractions, from the black and the white cat we have perhaps obtained "a general concept of cat" (ibid., 198). But, "by continued application of this procedure, each object is transformed into a more and more bloodless phantom. As the end result, we obtain from each object a something emptied of all content; but the something obtained from one object differs nevertheless from the something obtained from another object, even though it is not easy to say how" (ibid.).
4. By abstraction from sensible things we cannot obtain mathematical objects whenever the attributes which are considered are subordinate to those which are left out. For example, suppose that there are a black and a white cat sitting side by side before us, and that we do not attend to what distinguishes them from all the other things. We thus obtain the concept of two "something." But, from the concept of two "something," if we do not attend to "something," we do not obtain the concept of two, since then there would not be left any more things of which one could say that there are two of them. Therefore, Frege says that if, "in considering a white cat and a black cat, I disregard the properties which serve to distinguish them," I do not obtain the concept "two" but rather "the concept 'cat'" (Frege 1960, 45). The "concept 'cat', no doubt, which we have arrived at by abstraction, no longer includes the special characteristics of either, but of it, for just that reason, there is only one" (ibid., 45–46).
5. By abstraction from sensible things, we may arrive at extravagant results. As Frege ironically says, the supporters of abstraction consider directing attention away from something an operation that "is especially effective. We attend less to a property, and it disappears. By thus making one characteristic mark after another disappear, we obtain more and more abstract concepts," therefore "inattention is a most effective logical power; this is presumably why professors are absent-minded" (ibid., 197). But directing attention away from something leads to absurdities. For example, "if, abstracting from the distinction between my house and that of my neighbour, I were to regard them as the same, and consequently act in the other house as in my own, then the erroneousness of my abstraction would soon be made clear to me" (Frege 2013, I, 107).

4 Mathematical Objects as Logical Objects

Another answer to the question "What is the nature of mathematical objects?" is that they are logical objects, because they are definable in terms of logical concepts, and all their properties are deducible from logical principles. This conception of mathematical objects has been put forward by Leibniz, Frege, and Russell.

For example, Russell says that all pure mathematics deals with objects "definable in terms of a very small number of fundamental logical concepts" and "all its propositions are deducible from a very small number of fundamental logical principles" (Russell 2010, xliii). In particular, it is possible to "reduce arithmetic, and above all the definition of numbers, to logic" (Russell 1992, 33). This view "was strongly advocated by Leibniz" but, owing to the limitations of his logic, Leibniz failed "in the endeavour to carry out in detail a view which, in its general outline, is now known to be correct" (ibid., 5).

Indeed today, "thanks to the progress of symbolic logic," all "mathematics can be strictly and formally deduced" from logical premisses, "and all the entities that occur in mathematics can be defined in terms of" the logical concepts "that occur in" those logical "premisses" (Russell 2010, 4–5). Therefore, "all mathematics is symbolic logic," and "when this fact has been established, the remainder of the principles of mathematics consists in the analysis of symbolic logic itself" (ibid., 5). Not only all mathematics is symbolic logic, but "it has now become wholly impossible to draw a line between the two; in fact, the two are one" (Russell 1993, 194).

The conception that mathematical objects are logical objects, however, has the following shortcomings.

1. Russell claims that all mathematical objects are definable in terms of logical concepts. But, while single natural numbers are definable in terms of logical concepts, not all their properties are deducible from logical principles, in particular, it is impossible to deduce from logical principles that there exist infinitely many natural numbers. Therefore, Russell is forced to introduce and axiom, the axiom of infinity, which postulates that there exist infinitely many natural numbers. But this is incompatible with the claim that all the properties of mathematical objects are deducible from logical principles. Even Russell admits that "the axiom of infinity" is "a proposition which, though it can be enunciated in logical terms, cannot be asserted by logic to be true" (Russell 1993, 202–203). For, "it seems plain that there is nothing in logic to necessitate its truth or falsehood, and that it can only be legitimately believed or disbelieved on empirical grounds" (Whitehead and Russell 1925–1927, II, 183).
2. Russell claims that all properties of mathematical objects are deducible from logical principles. Then, in particular, all arithmetic truths are deducible from logical principles L. But this is refuted by Gödel's first incompleteness theorem, by which there are arithmetic truths which are not deducible from L. Therefore, there are arithmetic truths which are not logical truths. Against this conclusion, Hale and Wright object that Gödel's first incompleteness theorem "might just as well" be "taken as revealing, not that there are arithmetic truths which are not"

logical truths, "but that logical truth likewise defies complete deductive characterization" (Hale and Wright 2001, 4, footnote 5). For, by the strong incompleteness theorem for second-order logic, not all logically valid second-order sentences are deducible from L. So, the fact that there are arithmetic truths which are not deducible from L, does not mean that there are arithmetic truths which are not logical truths. Such arithmetic truths might as well be logically valid sentences which are not deducible from L, and hence might be logical truths. Therefore, Hale and Wright conclude, "if the logicist is entitled to take logic as including second- and perhaps higher-order logic, then Gödel's incompleteness result has no specific bearing on the logicist project" (ibid., 5, footnote 5). But this objection is invalid because, by Gödel's first incompleteness theorem, the arithmetic truths which are not deducible from L are first-order sentences, and, by the completeness theorem for first-order logic, all logically valid first-order sentences are deducible from L. So, if the arithmetic truths in question were logically valid, being first-order sentences they would be deducible from L. Since they are not deducible from L, it follows that they cannot be logical truths. Therefore, contrary to Hale and Wright's objection, the claim that all arithmetic truths are deducible from certain logical principles L is refuted by Gödel's first incompleteness theorem.

5 Mathematical Objects as Simplifications

Another answer to the question "What is the nature of mathematical objects?" is that mathematics is ultimately about concrete spatiotemporal objects but, in order to demonstrate properties of such objects, abstract objects are added to the concrete ones, notably actual infinities. Their use can be justified by demonstrating, by absolutely reliable means, that it will lead to no contradiction. This conception of mathematical objects has been put forward by Hilbert.

Indeed, Hilbert says that mathematics is ultimately about "concrete" spatiotemporal "objects that are intuitively present as immediate experience prior to all thought" (Hilbert 1967b, 464). But, in order to demonstrate properties of such objects, abstract objects are added to the concrete ones, notably "the actual infinite" (Hilbert 1967a, 373). These abstract objects do not permit to demonstrate properties of concrete objects that could not be demonstrated without them, in particular "the modes of inference employing the infinite" can "be replaced generally by finite processes that have precisely the same results" (ibid., 370). But they are useful, because they significantly simplify the demonstration of such properties, which "results in the simplification and completion of the theory" (Hilbert 1996b, 1144).

However, since abstract objects are not immediately given in sensible intuition, operation with them "has proved to be inadequate and uncertain" (Hilbert 1996a, 1121). Now, the "extension by the addition" of abstract objects to concrete ones "is legitimate only if no contradiction is thereby brought about in the old, narrower domain" (Hilbert 1967b, 471). In order to ensure this, the theory must be "rigorously

formalized, so that mathematics" proper "becomes a stock of formulae" (Hilbert 1996c, 1152). Then one must demonstrate that, in the theory so formalized, "it is impossible for us to obtain two logically contradictory propositions" (Hilbert 1967b, 471). Moreover, one must demonstrate this by absolutely reliable means, namely, without using "any dubious or problematical mode of inference" (Hilbert 1996b, 1139). This will guarantee that operation with abstract objects "can never lead to a demonstrably false result" (Hilbert and Bernays 1968–1970, I, 44). To do so is always possible, because "there are absolutely no unsolvable problems" (Hilbert 1996d, 1165).

The conception that mathematical objects are simplifications, however, has the following shortcomings.

1. Hilbert assumes that a theory can always be formalized. But, by Gödel's first incompleteness theorem, this is generally impossible, because there will always be some sentence of the theory which is true but cannot be demonstrated in the theory.
2. Hilbert assumes that it is always possible to demonstrate, by absolutely reliable means, that in the theory so formalized no contradiction will arise. But, by Gödel's second incompleteness theorem this is generally impossible.
3. Hilbert assumes that to demonstrate, by absolutely reliable means, that in the theory so formalized no contradiction will arise, will guarantee that no falsity will be demonstrable in the theory. But it is not so because, by a corollary of Gödel's first incompleteness theorem, any consistent sufficiently strong formal system has a consistent extension in which some false sentence is demonstrable. In fact, Hilbert need not have waited for Gödel to realize that noncontradictoriness is no guarantee against falsity. Already Kant had made it clear that it is, "to be sure, a necessary logical condition" that in "a concept no contradiction must be contained," but this is "far from sufficient for the objective reality of the concept, i.e., for the possibility of such an object as is thought through the concept" (Kant 1998, A220/B268). It is not enough to assume, as "condition of all our judgments whatsoever," that "they do not contradict themselves," because "for all that a judgment may be free of any internal contradiction, it can still be either false or groundless" (ibid., A150/B190).

6 Mathematical Objects as Mental Constructions

Another answer to the question "What is the nature of mathematical objects?" is that they are mental constructions based on intuition. This means that they are not merely ideas conceived by the mind but are entities whose construction can be wholly accounted for in terms of acts of the mind based on intuition. This conception of mathematical objects has been put forward by Brouwer.

Indeed, Brouwer criticizes contemporary mathematics because it holds that mathematical objects "have mathematical existence" when "they have been represented in spoken or written language together with" the "laws upon which

their development depends" (Brouwer 1975, 83). So, contemporary mathematics "completely abandons any geometric or arithmetical intuition and confines its subject matter exclusively to the domain of mathematical language" (Brouwer 1998, 55). On the contrary, a mathematical object "is a mental construction, essentially independent of language" (Brouwer 1975, 477). It is not merely a linguistic object but a mental construction based on intuition, because "no mathematics can exist which has not been intuitively built up" (ibid., 52). For example, a natural number is a mental construction based on the "intuition of time" (ibid., 116). Mental constructions are the same in all individuals, because "it is an essential hypothesis for human understanding that the structure of" construction "is the same for all individuals" (ibid., 599). Therefore, the mental construction of the natural numbers is the same for all individuals. The "only possible foundation of mathematics must be sought in this construction under the obligation carefully to watch which constructions intuition allows and which not" (ibid.). Since contemporary mathematics abandons any geometric or arithmetical intuition and consider mathematical objects which cannot be intuitively built up, this requires "a new practice of creative mathematical work" (ibid., 477). Indeed, "several of the theories of mathematics proper" must be "built anew" (ibid., 412).

The conception that mathematical objects are mental constructions based on intuition, however, has the following shortcomings.

1. Brouwer criticizes contemporary mathematics for completely abandoning any geometric or arithmetical intuition and confining its subject matter exclusively to the domain of mathematical language. But his criticism is not motivated by any necessity of mathematical practice, it is only due to his purely ideological assumption that to be is to be constructed in intuition. This entails that important parts and results of modern mathematics must be rejected. As Weyl says, "with Brouwer, mathematics gains the highest intuitive clarity; his doctrine is idealism in mathematics thought to and end. But, full of pain, the mathematician sees the greatest part of his towering theories dissolve in fog" (Weyl 1998, 136). And the mathematician sees such theories dissolve in fog only to be replaced with surrogate theories which are weaker and quite awkward to use in practice.
2. Brouwer claims that a mathematical object is a mental construction based on intuition, for example, a natural number is a mental construction based on the intuition of time. The mental construction of the natural numbers is the same for all individuals. But, as Gillies points out, this contrasts with the fact that, "if we look at number systems historically, we find" that "different, and generally more primitive, systems existed for centuries in many parts of the world. Often there was a crucial innovation in some relatively small group, and this change gradually spread elsewhere," so "the system of natural numbers" was "constructed slowly and often painfully over long periods of time by human beings" (Gillies 2014, 26). Generally, "some mathematical concepts are counter-intuitive rather than natural, and are the result of centuries of trial and error rather than easy inferences from an *a priori* intuition" (ibid.).

3. Brouwer claims that no mathematics can exist which has not been intuitively built up. But this entails that there cannot exist mathematical objects which are important to physics. In particular, it entails there cannot exist everywhere defined discontinuous functions. This is not an oversight, but deliberate. For, Brouwer explicitly declares that he does not care a bit for the use of mathematics in physics, since mathematics is not aimed at "expansion of human domination over nature" but at beauty, and "things as such are not beautiful, nor is their domination by shrewdness" (Brouwer 1975, 483). Mathematics "is an art, its application to the world an evil parasite" (Borwein et al. 2004, 295).

7 Mathematical Objects as Structures

Another answer to the question "What is the nature of mathematical objects?" is that, rather than about objects, mathematics is about structures, where a structure is a collection of objects with certain relations among them, which however highlights the relationships between the objects, rather than the objects themselves. Objects are simply places in structures. This conception of mathematical objects has been put forward by Bourbaki, Shapiro, and Resnik.

For example, Shapiro says that "mathematics is the science of structure" (Shapiro 2000, 257). A structure is "a collection of objects with certain relations among them," highlighting "the interrelationships among the objects, and ignoring any features of them that do not affect how relate to other objects in the system" (ibid., 259). For example, "the subject-matter of arithmetic is a single abstract structure," the structure of natural numbers, that is "the pattern common to any infinite collection of objects that has a successor relation, a unique initial object, and satisfies the induction principle" (ibid., 258). Mathematical objects are merely positions in a structure, for example, "the number 2 is no more and no less than the second position in the natural number structure; and 6 is the sixth position. Neither of them has any independence from the structure in which they are positions, and as positions in this structure, neither number is independent of each other" (ibid.).

A "structure can be characterized by an axiomatization, which is an implicit definition" (Shapiro 2004, 32). Not every implicit definition, however, "successfully characterizes a structure," in order to characterize it an implicit definition must fulfill two conditions, the "existence condition" that "at least one structure" satisfies "the axioms," and the "uniqueness condition" that "at most one structure is described" (Shapiro 2000, 285). The uniqueness condition "depends on the underlying logic of the axiomatization," indeed, if the latter is taken to be second-order logic, then "there are unique characterizations of rich mathematical structures" (ibid.). In particular, there is a unique characterization of the structure of natural numbers. As to the existence condition, "in mathematics as practised, set theory" is "taken to be the ultimate court of appeal for existence questions," so "a certain type of mathematical objects" can be said to exist if "objects of this type can be found or modelled in the set-theoretic hierarchy" (ibid., 288). In fact, "set theory is the appropriate court of appeal because it is comprehensive. The set-theoretic hierarchy is so big that just

about any structure can be modelled or exemplified there" (ibid.). Thus, ultimately, "a structure is an equivalence class in the set-theoretic hierarchy" (Shapiro 1997, 92).

Since there are axiomatizations which give unique characterizations of rich mathematical structures, all the models of such characterizations are isomorphic. But, "since isomorphic models are equivalent, the relevant properties of any model of the axiomatization are the same, and so, in a sense, any model is as good as any other," therefore "we can learn about the structure by studying an exemplification of it" (Shapiro 2004, 32). For example, "the natural number structure is exemplified by various systems of natural numbers" (Shapiro 2008, 174). Therefore, we can learn about the structure of natural numbers by studying any of the systems of natural numbers by which the natural number structure is exemplified.

The conception that mathematical objects are structures, however, has the following shortcomings.

1. Shapiro claims that mathematics is the science of structure, but thus he mistakes for mathematics what is merely the mathematics produced by a particular school, the Göttingen's school, which, through Van der Waerden's *Moderne Algebra*, influenced Bourbaki. (On the Göttingen's school, see Ferreiros 1999; Ferreiros and Gray 2006). Contrary to his claim, there are many mathematical questions, such as the distribution of prime numbers or the transcendence of π, which are not questions about a structure.
2. Shapiro claims that a certain type of mathematical objects can be said to exist if objects of this type can be modelled in the set-theoretic hierarchy. But, as Shapiro himself acknowledges, "for the structuralist, the set-theoretic hierarchy is just another structure. What makes us think that set theory itself is coherent?" (Shapiro 2000, 288). Surely, "we cannot justify the coherence of set theory itself by modelling it in the set-theoretic hierarchy" (ibid.). The circle would be too blatant. Despite this, Shapiro claims that "the coherence of set theory is presupposed by much of the foundational activity in contemporary mathematics. Rightly or wrongly, mathematics presupposes that satisfiability (in the set-theoretic hierarchy) is sufficient for existence" (ibid., 288–289). Therefore, we must "accept this presupposition and make use of it like everyone else, and are in no better (and no worse) of a position to justify it" (ibid., 289). Such "presupposition is not vicious, even if it lacks external justification" (Shapiro 1997, 136). Contrary to Shapiro's claim, however, the presupposition in question is indeed vicious. Shapiro's argument is a *petitio principii* because it is similar to the argument that we must accept the existence of God because such existence is presupposed by the existence of the world.
3. Shapiro claims that ultimately a structure is an equivalence class in the set-theoretic hierarchy. But then the primitive concept of mathematics is the concept of set, not the concept of structure. To avoid this problem, Shapiro formulates an axiomatic theory of structures. However, this theory is entirely similar to set theory, and neither clarifies nor solves any problem that set theory does not solve. Shapiro himself admits that "the set-theoretic hierarchy and the realm of

structures are little more than notational variants of each other" (Shapiro 2004, 20). Then the concept of structure is just the concept of set in disguise.

4. Shapiro claims that we can learn about the structure of natural numbers by studying any of the systems of natural numbers by which the natural number structure is exemplified. But Zermelo's and von Neumann's provide two different exemplifications of the structure of natural numbers. In Zermelo's exemplification 0, 1, 2, 3, . . .are $\emptyset$, $\{\emptyset\}$, $\{\{\emptyset\}\}$, $\{\{\{\emptyset\}\}\}$, . . ., while in von Neumann's exemplification they are $\emptyset$, $\{\emptyset\}$, $\{\emptyset, \{\emptyset\}\}$, $\{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$, ... According to Shapiro, the only thing that matters about the natural number structure is the relation between natural numbers. Now, in both such exemplifications, the relation between the natural numbers is the membership relation, and yet the membership relation has different properties in each of them, even properties which are inconsistent with each other. Thus, in Zermelo's exemplification, $1 \notin 3$ because 1 is $\{\emptyset\}$ and 3 is $\{\{\{\emptyset\}\}\}$, while in von Neumann's exemplification, $1 \in 3$ because 1 is $\{\emptyset\}$ and 3 is $\{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$. Which is the correct exemplification? Structuralism can give no answer.

8 Mathematical Objects as Fictions

Another answer to the question "What is the nature of mathematical objects?" is that they are fictions. This conception of mathematical objects has been put forward by Field, Balaguer, and Yablo.

Thus, Field says that mathematical objects are fictions as the characters of a story, because all there is to mathematics is that "we have a good story about natural numbers, another good story about sets, and so forth" (Field 1989, 22). A mathematical proposition is true only in the same sense in which the proposition "'Oliver Twist lived in London' is true: the latter is true only in the sense that it is true according to a certain well-known story, and the former is true only in the sense that it is true according to standard mathematics" (ibid., 3).

Nevertheless, even though mathematics is about fictional objects, mathematics is useful because we can use it "as a device for drawing conclusions" about the physical world "much more easily than we could draw them by a direct proof" (Field 1980, 28). On the other hand, since mathematics is about fictional objects, "it would be extremely surprising if it were to be discovered that standard mathematics implied that there are at least 10^6 non-mathematical objects in the universe, or that the Paris Commune was defeated" (ibid., 13).

To make sure that this will not occur, it is necessary to prove that mathematics is conservative over physics. Namely, it is necessary to prove that the conclusions we arrive at by adding a mathematical theory to a physical theory which makes no reference to mathematical entities "are not genuinely new, they are already derivable in a more long-winded fashion from the premises" of the physical theory, "without recourse to the mathematical entities" (ibid., 10–11). If this could be proved, it would be made sure that any deduction "that can be made with the help of mathematics could be made (usually more long-windedly) without it" (ibid., x). One could then assert that "that mathematics is not really indispensable after all" (Field 1989, 26). And one

would be "free to use any mathematics he likes for deducing consequences, as long as" one can always dispense with "the mathematics he uses" (Field 1980, 14).

Now, it can be proved that mathematics is conservative over physics. For, "there are some fairly general strategies that can be employed to purge" physical "theories of all reference to mathematical entities" (Field 1989, 18). The paradigmatic example of this is "a rewritten version of Newtonian physics" in which individual variables range over concrete objects, which amounts to "formulating it without mathematical entities" (ibid., 18, footnote 11).

The conception that mathematical objects are fictions, however, has the following shortcomings.

1. Field claims that all there is to mathematics is that we have a good story about natural numbers, another good story about sets, and so forth, and that a mathematical proposition is true only in the same sense in which the proposition "Oliver Twist lived in London" is true. But Dickens did not first introduce the character Oliver Twist and then investigated him, discovering that Oliver was a small boy whose mother dies the moment he is born, who lives in a poorhouse and ends up getting involved with a gang of thieves, but eventually is adopted by a kind-hearted and rich man. Dickens made up the character Oliver Twist with all his features through his story. On the contrary, a mathematician first introduces certain mathematical objects and then investigates them, discovering some of their properties, afterwards some other mathematician discovers other properties, and so on. Therefore, mathematical objects are essentially different from characters in a story.
2. Field claims that it can be proved that mathematics is conservative over physics, but this claim is unwarranted. For, let M be a mathematical theory that is added to a physical theory N which makes no reference to mathematical entities. In order to prove that mathematics is conservative over physics, one should prove that, if a sentence A of N is provable in $N + M$, then A is provable already in N. But, as Shapiro points out, since there is a one-to-one correspondence between space-time points and quadruples of real numbers, "it is possible to model the natural numbers in space-time and, in effect, to do arithmetic in N. To put it differently, the natural number structure is exemplified in the universe of space-time" (Shapiro 1983, 526). Then "the Gödel's incompleteness theorems apply" (ibid., 527). Therefore, there is a sentence A of N which is provable in $N + M$ but not in N. Thus, the mathematical theory M is not conservative over the physical theory N, which refutes the fictionalist "argument for the conservativeness of mathematics over physics" (ibid., 528).
3. Field claims that the paradigmatic example of the fact that there are some fairly general strategies that can be employed to purge physical theories of all reference to mathematical entities is a rewritten version of Newtonian physics in which individual variables range over concrete objects. But this claim is unwarranted. For, in order to make a rewritten version of Newtonian physics in which individual variables range over concrete objects, one is bound to introduce entities having properties of mathematical entities, rather than properties of concrete

objects. For example, the postulates of Field's theory of space-time entail that there is a one-to-one correspondence between space-time points, conceived of as physical entities, concrete and not abstract, and quadruples of real numbers. Since real numbers are uncountable, this involves postulating uncountably many physical entities. According to Field, this is not objectionable, nor "does it become any more objectionable when one postulates that these physical entities obey structural assumptions analogous to the ones that platonists postulate for the real numbers" (Field 1980, 31). But, then, what Field calls "physical entities" are really mathematical entities, and hence the rewritten version of Newtonian physics does not really purge Newtonian physics of all reference to mathematical entities.

9 Mathematical Objects as Idealizations of Sensible Things

Another answer to the question "What is the nature of mathematical objects?" is that they are ideal objects obtained from sensible things not by abstraction but by idealization. The latter is the process by which one pushes certain attributes of sensible things to the limit, for example, the concept of sphere is obtained by pushing certain attributes of a ball to the limit. Thus, while objects obtained by abstraction from sensible things have attributes which also occur in sensible things, objects obtained by idealization have attributes which do not occur in sensible things. This conception of mathematical objects has been put forward by Husserl.

Indeed, Husserl says that "the mathematical realm" is "a world of ideal objects" (Husserl 2008, 49). These ideal objects, the mathematical objects, are the result of "idealizing the world of bodies in respect to what has spatiotemporal shape in this world," so such idealization "created ideal objects" (Husserl 1970, 32). Being the result of idealizing the world of bodies, mathematical objects express "something which cannot be 'seen'," they are "essences drawn immediately from intuition simpliciter" as "ideal essences" (Husserl 1983, 166). The ideal essences are "ideal 'limits' which it is essentially impossible to find in any sensuous intuition" (ibid., 167). They are the product of an idealization, which "is fundamentally different in its essence from the seizing upon an essence by simple 'abstraction'" (ibid., 167).

The conception that mathematical objects are idealizations of sensible things, however, has the following shortcomings.

1. Husserl claims that the mathematical realm is a world of ideal objects. This raises the question: If the mathematical realm is a world of ideal objects, why is mathematics applicable to the real world? Husserl's answer is that it is applicable to it because, "through Galileo's mathematization of nature, nature itself is idealized" and "becomes" a "mathematical manifold" (Husserl 1970, 23). So, Galileo substitutes a "mathematically substructed world of idealities for the only real world, the one that is actually given through perception, that is ever experienced and experienceable" (ibid., 49). Thus, Galileo conceives the "idea of a rational infinite totality of being with a rational science systematically mastering

it" (ibid., 22). Then, however, Husserl does not really account for the applicability of mathematics to the real world, but only for the applicability of mathematics to a mathematically substructed world of idealities. So, the problem is not solved but only transformed in the problem of why, if mathematics is applicable to a mathematically substructed world of idealities, it is also applicable to the world.

2. Husserl claims that mathematical objects are the product of an idealization of sensible things, which is fundamentally different in its essence from the seizing upon an essence by simple abstraction. Being the product of an idealization, mathematical objects have attributes which do not occur in sensible things. Then, however, Husserl not only does not really account for the applicability of mathematics to the real world, but even trivializes the question of the applicability. For, if mathematical objects have attributes which do not occur in sensible things, then all mathematical propositions are vacuously true in the real world. For example, such is the proposition "In any triangle, the interior angles are equal to two right angles." For, the proposition is of the form $P(x) \rightarrow Q(x)$, where $P(x)$ expresses "x is a triangle" and $Q(x)$ expresses "The interior angles of x are equal to two right angles." Since, according to Husserl, triangles have attributes which do not occur in sensible thing, $P(x)$ is false and hence $P(x) \rightarrow Q(x)$ is vacuously true in the real world. For the same reason, even the opposite proposition, "In any triangle, the interior angles are not equal to two right angles," being of the form $P(x) \rightarrow \neg Q(x)$, is vacuously true in the real world.

10 Mathematical Objects as Idealizations of Operations

Another answer to the question "What is the nature of mathematical objects?" is that they are idealizations of operations of collecting and segregating performed by an ideal subject. This conception of mathematical objects has been put forward by Kitcher.

Indeed, Kitcher says that mathematical objects are idealizations "of operations of collecting" and segregating "which we are able to perform with respect to any objects" (Kitcher 1983, 12). Or rather, since, "given our biological limitations, the operations in which we actually engage are limited," mathematical objects are idealizations of operations of collecting and segregating performed by an "ideal subject, whose status as an ideal subject resides in her freedom from certain accidental limitations imposed on us" (ibid., 109). The ideal subject is not a mysterious being, but only "an idealization of ourselves" (ibid., 111). The relation between the operations of the ideal subject and "the actual operations of human agents parallels that between the laws of ideal gases and the actual gases which exist in our world" (ibid., 109). Ideal gases do not exist in our world, and yet "actual gases approximately satisfy the condition set down in the Boyle-Charles Law" of ideal gases; moreover, "if the molecules of gases were of negligible size and if there were no intermolecular forces then gases would obey the Boyle-Charles Law" (ibid., 117). This "prompts us to abstract from certain features of the actual situation, introducing the notion of an ideal gas to describe how actual gases would behave if complicating

factors were removed" (ibid.). Much in the same way, the ideal subject does not exist in our world, and yet the actual operations of collecting and segregating of human agents approximate the operations of the ideal subject, and moreover, if human agents were free from their biological limitations, their operations would coincide with those of the ideal subject. This prompts us to "specify the capacities of the ideal agent by abstracting from the incidental limitations on our own collective practice" (ibid.).

That mathematical objects are idealizations of operations of collecting and segregating also includes sets. According to Kitcher, sets are members of the hierarchy which "arises from the iterated performance of one fundamental operation, that of collecting," and its description "may be viewed as a literal account of the iterated constructive activity of the ideal mathematical subject" (ibid., 133). This amounts "to ascribe to the ideal subject an ability to perform iterative collective activity through an infinite sequence of stages" (ibid., 147). Since "the sequence of stages at which sets are formed is highly superdenumerable," it follows that, if "each of the stages corresponds to an instant in the life of the constructive subject," then "the subject's activity is carried out in a medium analogous to time, but far richer than time. (Call it 'supertime')" (ibid., 146). Admittedly, this means "to idealize still further from our own thoroughly finite performances" (ibid., 147). But such idealization "is no different in principle from earlier idealizations in which we abstract from our own mortality or from our inability to survey infinite domains. The conception of the ideal subject as an idealization of ourselves does not lapse when we release the subject from the constraints of our time" (ibid.). Thus, to talk of such an ideal subject "is not to suppose that there is a mysterious being with superhuman powers" (ibid., 110).

The conception that mathematical objects are idealizations of operations of collecting and segregating that an ideal subject performs, however, has the following shortcomings.

1. Kitcher claims that, as ideal gases do not exist in our world and yet actual gases approximately satisfy the laws of an ideal gas, so the ideal subject does not exist in our world, nevertheless the actual operations of collecting and segregating of human agents approximate the operations of the ideal subject. But this overlooks that actual gases very closely approximate ideal gas behavior at high temperatures and low pressures, and the degree of approximation can be calculated. On the contrary, the ideal subject is supposed to be able to perform certain operations, such as all possible collecting of the members of an uncountable totality, which are far beyond the possibilities of any human agent.
2. Kitcher claims that the description of the hierarchy of sets may be viewed as a literal account of the iterated constructive activity of the ideal subject. Now since, as Kitcher admits, the sequence of stages at which sets are formed is highly superdenumerable, this entails that the ideal subject should be able to perform superoperations in a super-time. But, while actual gases approximately satisfy the laws

of an ideal gas, the structure of our time by no means approximates the structure of such super-time since the latter is highly super-denumerable.

Actually, an ideal subject capable of performing super-operations in a super-time would be not only super-human but also super-divine. Indeed, as Parsons points out, the mind of such an ideal subject "would differ not only from finite minds but also from the divine mind as conceived in philosophical theology" (Parsons 2005, 273). For, in the latter, either the divine mind "is thought of as in time, and therefore as doing things in an order with the same structure as that in which finite beings operate, or its eternity is interpreted as complete liberation from succession" (ibid.).

3. Kitcher claims that to view the description of the hierarchy of sets as a literal account of the iterated constructive activity of the ideal mathematical subject means to make an idealization that is no different in principle from earlier idealizations in which we abstract from our own mortality or from our inability to survey infinite domains. Hence, Kitcher concludes that it is unjustified to say that to talk of such an ideal subject is not to suppose that there is a mysterious being with superhuman powers. But this overlooks that an ideal subject who constructed the hierarchy of sets would be a being whose mind would differ not only from human minds but, by what has been said above, also from the divine mind. Therefore, to talk of such an ideal subject would be just to suppose that there is a mysterious being with superhuman powers.

11 The Basis for an Alternative Conception

Since all conceptions of mathematical objects discussed above have substantial shortcomings, one may wonder whether there is an alternative conception not subject to them. However strange this may sound, the basis for such an alternative conception of mathematical objects can be found in Plato.

Admittedly, as we have seen, Plato says that mathematical objects are ideas in themselves, which have a kind of reality not perceptible by any sense and such that only intuition can contemplate it.

But Plato also says that mathematicians, as long as they are alive, cannot contemplate this kind of reality by intuition. For, as long as they have the body and their soul is contaminated by such an evil, they will never adequately gain the possession of what they desire, that is, truth. Only after death, mathematicians can behold "the happy vision and contemplation" of the reality in question, having "calm and happy visions, in pure light" (Plato, *Phaedrus*, 250 b 8–c 4).

Since mathematicians, as long as they are alive, cannot contemplate the kind of reality of which mathematical objects consist by intuition, in order to solve mathematical problems, they introduce certain mathematical objects as hypotheses.

Indeed, Plato says that, in order to solve a mathematical problem, mathematicians must "make use of a hypothesis" (Plato, *Meno*, 86 e 3). In fact, "those who deal with

geometry, arithmetic, and the like, hypothesize the odd and the even, geometrical figures, the three kinds of angles, and other things akin to these, depending on the subject of their investigation. They take these as known and assume them as hypotheses" (Plato, *Republic*, VI 510 c 2–6). So, they arrive at knowing the properties of these objects, not by intuition, but by making hypotheses, hence through discursive thought. Thus, it is "discursive thought, not intuition, the state of geometry and the like, namely, thought intermediate between opinion and intuition" (ibid., VI 511 d 2–5).

According to Plato, this is the only way in which mathematicians, as long as they are alive, can solve mathematical problems.

12 The Heuristic Conception of Mathematical Objects

Plato's statements suggest that mathematical objects are hypotheses human beings make to solve mathematical problems. Specifically, they are hypotheses human beings make to solve mathematical problems by the analytic method.

The analytic method is the method according to which, to solve a problem, one looks for some hypothesis that is a sufficient condition for the solution of the problem. The hypothesis is obtained from the problem, and possibly other data, by some nondeductive rule and must be plausible, that is, the arguments for it must be stronger than the arguments against it, on the basis of experience. But the hypothesis is, in turn, a problem that must be solved and is solved in the same way. That is, one looks for another hypothesis that is a sufficient condition for the solution of the problem posed by the previous hypothesis. The new hypothesis is obtained from the previous hypothesis, and possibly other data, by some nondeductive rule, and must be plausible. And so on, ad infinitum. Therefore, the solution to a problem is a potentially infinite process (For details on the analytic method, see Cellucci 2013).

The status of mathematical objects is similar to that of the theoretical terms of physical theories, which are hypotheses human beings make to solve physical problems by the analytic method.

This is the heuristic conception of mathematical objects.

Of course, in the heuristic conception, since mathematical objects are hypotheses human beings make to solve mathematical problems by the analytic method, the hypotheses in question must be plausible, that is, such that the arguments for them are stronger than the arguments against them, on the basis of experience. Only mathematical objects given by hypotheses which are plausible can be said to "exist." But this does not mean that they exist literally, in the physical or in a superphysical world. For, hypotheses are only ideas conceived by the mind. On the other hand, not all ideas conceived by the mind can be accepted as mathematical objects, but only those which are plausible. Therefore, that mathematical objects exist means that they are given by hypotheses which are plausible.

13 Some Remarks about the Heuristic Conception

Some remarks about the heuristic conception of mathematical objects may be useful.

1. That mathematical objects are hypotheses human beings make to solve mathematical problems by the analytic method, does not mean that they are mental constructions in Brouwer's sense. For, hypotheses are simply ideas conceived by the mind. Conversely, mental constructions in Brouwer's sense are entities whose construction is accounted for in terms of acts of the mind based on intuition, which are "acts of mathematical construction" (Brouwer 1975, 88). This makes a great difference in practice. For example, actual infinities can be introduced as hypotheses to solve mathematical problems, but they are not mental constructions in Brouwer's sense, because they are "certainly not built up mathematically" (ibid., 80).
2. That mathematical objects are hypotheses human beings make to solve mathematical problems by the analytic method, does not mean that they are fictions. For, hypotheses are introduced to deal with the world, so they must agree with experience and are accepted until strong arguments against them emerge. Conversely, fictions are not introduced to deal with the world, so they are not supposed to agree with experience, and are accepted despite our being aware that they have no basis in experience. As Vaihinger, the founder of philosophical fictionalism, says, "whereas every hypothesis seeks to be an adequate expression of some reality still unknown and to mirror this objective reality correctly, the fiction is advanced with the consciousness that it is an inadequate" manner "of conception, whose coincidence with reality is, from the start, excluded" (Vaihinger 2008, 268).
3. That mathematical objects are hypotheses human beings make to solve mathematical problems by the analytic method, means that they are mental-cultural human products. To solve some mathematical problem, one or more mathematicians may conceive the idea of certain new mathematical objects, and use such idea as hypothesis to solve the problem by the analytic method. Afterwards, other mathematicians may find the hypothesis useful to solve other problems by the analytic method. And so on. Thus, in addition to being conceived by the mind of one or more mathematicians, mathematical objects become part of the cultural process as cultural products. Therefore, as White says, the introduction of new mathematical objects is "an event that takes place" both "in one or more nervous systems" and "in the cultural tradition," where "the human nervous system" is "the catalyst which makes the cultural process possible" (White 1947, 303). Of course, like all other cultural products. Newly introduced mathematical objects may encounter resistance. For example, such has been the case of the number zero, negative numbers, infinitesimals, complex numbers, actual infinities.
4. The hypotheses by which mathematical objects are introduced characterize their identity, but do not entail that those mathematical objects exist – just as saying that hippogriffs are animals having the foreparts of a griffin and the body of a

horse characterizes their identity, but does not entail that hippogriffs exist. Identity does not entail existence. As already said above, in order to say that mathematical objects exist, one must show that the hypotheses by which they are given are plausible.

5. That mathematical objects are introduced as hypotheses by some mathematician does not mean that such mathematician knows all their properties. Gödel says that "the creator necessarily knows all properties of his creatures, because they can't have any others except those he has given to them" (Gödel 1986–2002, III, 311). But it is not so. A painter does not necessarily know all properties of his creatures, otherwise there would be no need for art critics. It is one thing to introduce mathematical objects as hypotheses, and another thing to discover all their properties. For example, "when Cardano introduced his complex numbers, he could have had no inkling of the many magical properties which were to follow – properties which go under various names, such as the Cauchy integral formula, the Riemann mapping theorem, the Lewy extension property" (Penrose 1991, 96). These properties, and many others, do not pertain to later modifications of the concept of complex number, but are "properties of the very numbers" that "Cardano had first encountered in about 1539" (ibid.). Cardano could have had no inkling of such properties because mathematical objects, entering into relation with other mathematical objects, acquire new properties, other than those the creator has given to them, and to discover them requires an investigation.

14 Conclusion

It has been said above that the hypotheses by which mathematical objects are introduced characterize their identity. This, however, does not mean that the hypotheses characterize their identity completely and conclusively. The identity may undergo changes, because mathematical objects are not closed in themselves, they are open to interactions with other mathematical objects, from which they gain new determinations.

Moreover, mathematical objects introduced to solve a particular problem may turn out to be useful to solve other problems. Such objects, then, consolidate, crystallize, and acquire a stability which makes them amply independent of the problem for which they were originally introduced, and become subjects of study themselves.

For example, Menaechmus introduced conic sections to solve the problem of finding two mean proportional lines between two given lines (see Cellucci 2013, Sect. 4.9). But, afterwards, conic sections turned out to be useful to solve other problems, and eventually became subjects of study themselves as in Apollonius of Perga's treatise *Conics*, one of the greatest scientific works from the ancient world.

When mathematical objects become subjects of study themselves, they may appear so familiar to us that they may seem to be independently existing entities. We may have the impression that, as Hermite says, they are not "arbitrary product of our minds," but entities which "exist outside of us with the same character of

necessity as the objects of objective reality; and we find or discover them and study them as do the physicists, chemists and zoologists, etc." (Hermite 1905, 398). But this is an illusion, which arises from our great familiarity with them. Mathematical objects are not independently existing entities, because the conception that mathematical objects are independently existing entities has the severe shortcomings already spelled out in detail earlier in this chapter.

On the other hand, other mathematical objects, also introduced to solve a certain mathematical problem, do not consolidate nor acquire stability. They hang fluttering between being and non-being, and eventually disappear from mathematics.

For example, Newton and Leibniz introduced infinitesimals to solve problems concerning continuous change. To that aim, Newton said it was useful to imagine "infinitely small additions" by which "quantities increase during each infinitely small interval of time" (Newton 1967–1981, III, 81). Leibniz said it was "useful to imagine infinitely small quantities, or, as Nicolaus Mercator called them, infinitesimals, which may not be taken to be zero when the assignable ratio between them is sought," but "are rejected whenever they are added to incomparably greater quantities" (Leibniz 1971, IV, 63). But infinitesimals never acquired stability, no precise definition of them was ever given, and they were even assigned contradictory determinations. Therefore, they were the object of severe criticism, such as that of Berkeley who said that infinitesimals "are neither finite quantities, nor quantities infinitely small, nor yet nothing," and hence may be called "the ghosts of departed quantities" (Berkeley 1992, 199). As a result, infinitesimals never crystallized and became subjects of study themselves, but hung fluttering between being and non-being, and in the nineteenth century disappeared from mathematics, only to be revived in the twentieth century by Robinson, in a completely different form, as "the infinitely small" numbers "of a non-standard model of Analysis" (Robinson 2016, 282).

That mathematical objects can gain new determinations from interactions with other mathematical objects, and may acquire stability becoming subjects of study themselves or may not crystallize eventually disappearing from mathematics, shows that mathematical objects have an open-ended character because such is the character of the hypotheses by which they are introduced.

Abstract

This chapter introduces the concept of *radical* Pythagorean mathematics, as part of mathematical modernism, which emerged around 1900 and extends to our own time. Arguably, the greatest discovery of Pythagorean mathematics of (sixth-fifth century BC) was that of the incommensurability of the side and the diagonal of the square. This discovery established the complex relationships between geometry and arithmetic and, correlatively, the possibility of a type of logos, a logos containing the alogon within it – a logical thought containing the unthinkable within it. I shall call the mathematics defined by this combination "Pythagorean mathematics." I shall argue that, as part of mathematical modernism, there emerged a new attitude toward the unthinkable in thought, an attitude that accepts this situation as a positive, enabling condition of thinking and knowledge. I shall call the mathematical thinking defined by this attitude, while keeping the irreducible relationship between geometry and algebra (which subsumes arithmetic within it), *radical* Pythagorean mathematics. The original Pythagorean attitude, at

least in one reconstitution of Pythagorean thought, was, as against the Platonist attitude, tolerant of this condition, but still sought to overcome it by finding a logos without the alogon within it. This attitude, often sliding into a Platonist one, has remained dominant throughout the history of mathematics, physics, and philosophy, including during the modernist period, notable as much for the presence of the radical Pythagorean thinking as for a resistance to it.

1 Introduction: The Ghost of Pythagoras

Pythagorean mathematics (the sixth–fifth century BC) had a profound influence on the subsequent history of mathematics and physics, from ancient Greece to our own time. The Pythagorean theorem alone would be sufficient to testify to this influence. To name only a few important examples of its role beyond Euclidean geometry, it figured in calculus (a tangent to a curve), complex numbers (the modulus of a complex number), differential and then Riemannian geometry (a tangent space to a manifold and a tangent bundle), and vector spaces, in mathematics. In physics, it was indispensable to all three main areas of modern (mathematical-experimental) physics: classical physics, special and general relativity theory, and finally, and most pertinently to my argument here, quantum mechanics, where the analog of the Pythagorean theorem in Hilbert spaces (vector spaces, possibly of infinite dimensions) over **C**, which define the mathematical formalism of the theory, plays a key role.

Arguably, the greatest, or at least, conceptually most remarkable, discovery of Pythagorean mathematics was, however, that of the incommensurability (alogon) of the side and the diagonal of the square, actually a consequence of the Pythagorean theorem as well. This discovery led to a great crisis, responsible for the shift from arithmetic to geometry as the *dominant* way of mathematical thinking in ancient Greek mathematics, eventually making possible a theory of proportion applicable to incommensurable as well as commensurable magnitudes, and with it, establishing the more complex relationships between geometry and arithmetic. Obviously (hence, my emphasis), arithmetic never left the stage of and remained indispensable to ancient Greek mathematics. This complexity has accompanied the relationships between geometry and arithmetic, and eventually algebra, throughout the subsequent history of mathematics until our own time, sometimes returning algebra to a more dominant role in mathematics. It had, however, taken more than two millennia before a proper theory of irrational numbers was developed by R. Dedekind and others, although algebra had of course worked with irrational numbers long before then.

Conceptually and philosophically, this discovery established, against the Pythagoreans' own grain, at least a *possibility* of new type of logos, a logos containing the alogon within it – mathematical or any logical thought containing within it that which is beyond it, or in our Latinized terms, the rational containing the irrational within itself. My double qualification, "against the Pythagoreans' own grain" and a "possibility," is prompted by the complexities, to be considered presently, of strictly attributing this logos to the Pythagoreans or, assuming the Pythagoreans entertained this possibility (as they, as I shall suggest, might have), of aiming to establish the scope of such a logos in their thinking. However, even establishing a possibility of such a logos was a momentous event. I shall call the mathematics defined by this possibility, along with the complex interplay of geometry and arithmetic, and eventually algebra, "Pythagorean mathematics" (to be distinguished from mathematical Pythagoreanism (e.g., Kahn 2001)). I shall also argue that, as part of mathematical modernism, which took the center stage of mathematics around 1900 and has continued to occupy it until our own time, there emerged a *new attitude* toward the unthinkable in thought (the alogon in a logos), in mathematics itself and in physics, as, from Galileo on, a mathematical science of nature. This attitude accepts the presence of the alogon within a logos as an enabling condition of thinking and knowledge. I shall call the mathematical thinking, in mathematics and physics, accompanied by this attitude, while keeping the irreducible relationship between geometry and algebra (which subsumes arithmetic within it), "radical Pythagorean mathematics."

The "original" Pythagorean attitude *appears* to have been, as against the Platonist attitude, *tolerant* of this condition, but saw it as an obstacle to thought and sought to overcome it in favor of a logos without the alogon within it. The actual thinking of the Pythagoreans themselves concerning the subject is, again, difficult to ascertain, and it might be debated (hence, my quotation marks around "original" and my emphasis on "appears"). This makes it more prudent to speak of the *Pythagorean* attitude rather than that of any particular Pythagorean figure and similarly of the *Platonist* attitude (which I shall contrast to the Pythagorean one) rather than Plato's own, incomparably greater textual evidence for assessing it notwithstanding, given that Plato's views on this (or most other subjects) are a matter of interpretation and debate as well. Still, while each attitude qua attitude may be ascertained with more (even if not complete) certainty and evidence in the work of many specific figures during the modern (from roughly sixteenth century on) and then the modernist period, when referring to actual ancient Greek thinking, one deals with a reconstitution of this thinking, a reconstitution that, while it may be plausible, may be questioned in one degree or another. Given this qualification it would be more accurate to speak of a *conservative* rather than, as I did above, *original* Pythagorean attitude, but for simplicity, I shall from now on use the Pythagorean attitude, thinking, or mathematics, only qualifying when necessary, while always using the *radical* Pythagorean attitude, thinking, or mathematics. The (conservative) Pythagorean attitude, often sliding into the Platonist one, has remained dominant throughout the history of mathematics, including in twentieth- and twenty-first-century mathematics, the epoch of mathematical modernism, in which, amidst a more

overt dominance of algebra, geometry, in a new synergy with algebra, came to play a new role and gave rise to new forms of geometry as well. The same attitude has been no less prevalent throughout the history of physics, from Descartes and Galileo (or indeed Aristotle) on, or the history of philosophy, from and before Plato on, until our own time. While it emerged along with modernism in mathematics and physics, radical Pythagorean attitude, advocated as it is here, has always been and remains a minority position, and the modernist period was notable as much for the presence of radical Pythagorean thinking as for a resistance to it.

The discovery of the incommensurables undermined the Pythagorean belief that the harmony of the ultimate nature of reality could be expressed in terms of numbers and their commensurable ratios and led to a shift from the dominance of arithmetical to that of geometric thinking. The discovery and the narrative of this discovery were accompanied by a narrative, a legend, of the fate of the one who made this discovery public, sometimes identified with the discoverer. Hippasus is often mentioned in either or both roles, but others are mentioned as well. The account is given in the first scholium of Book X of *Euclid's Elements*. According to T. Heath:

> The scholium quotes . . . the legend according to which "the first of the Pythagoreans who made public the investigation of these matters perished in a shipwreck," conjecturing that the authors of this story "perhaps spoke allegorically, hinting that everything irrational and formless is properly concealed, and, if any soul should rashly invade this region of life and lay it open, it would be carried away into the sea of becoming and be overwhelmed by its unresting current." There would be a reason also for keeping the discovery of irrationals secret for the time in the fact that it rendered unstable so much of the groundwork of geometry as the Pythagoreans had based it upon the imperfect theory of proportions which applied only to numbers. . .. [T]he discovery of incommensurability must have necessitated a great recasting of the whole fabric of elementary geometry, pending the discovery of the general theory of proportion applicable to incommensurable as well as to commensurable magnitudes. (Euclid 1989, vol. 3, p. 1)

This recasting becomes especially apparent when one compares Book V and Books VII–IX, which bring to the *Elements* theories of proportion, one for numbers and one for all magnitudes. As a result, there also emerged the separation between continuous (geometrical) and discontinuous (numerical) entities and thus geometry and arithmetic. (I am grateful to an anonymous reader of this chapter for suggesting this formulation and for directing my attention to the books of the *Elements* mentioned here.) Neither separation, I argue, has ever become complete but instead has continued to be underlain by a complex interplay of continuity and discontinuity, and geometry and arithmetic and then algebra. I further argue that this interplay has never been brought to a complete synthesis either in the history of mathematics from that point on, a history that, on the other hand, has multiplied this interplay and the forms of geometry and arithmetic and then algebra (itself a product of this unfolding multiplicity) themselves. The same, in part correlatively, might be said for the history of mathematical (or philosophical) concepts of continuity and discontinuity, and their interplay, which took an entirely unexpected form with modernism, especially in set theory in mathematics and quantum theory in physics, which, as explained

below, related continuous mathematics to discrete physical phenomena in a way never found or even contemplated in physics previously.

A remarkable aspect of the discovery of the incommensurables was the capacity of mathematics to discover the alogon within it by a rigorous mathematical procedure, by the logos of mathematics itself. In this respect, it was akin to K. Gödel's incompleteness theorems. These theorems proved mathematically the incapacity of a mathematical system, if it is rich enough to contain arithmetic (as is most of mathematics), to mathematically account for itself, by demonstrating all of its propositions to be provable as either true or false, which is Gödel's first incompleteness theorem, and, as a consequence, to be able to mathematically establish its consistency, which is Gödel's second incompleteness theorem. The second theorem still allows that such a system could be proven to be inconsistent. I shall discuss the significance of Gödel's findings in the present context in Sect. 4.

Once, however, the irrational within the rational, the alogon within a logos, is established, the question arises concerning the status of and the attitude toward this irrationality. Plato is the case in point in ancient Greek thinking, in his concern with the logos of philosophy as a logos without the alogon within it, against the mathematical, Pythagorean, logos of his time, that emerged, even if, again, only as a possibility, with the discovery of the incommensurables. The subject is discussed in several dialogues, such as *Meno*, *Theaetetus*, *Statesman*, and the *Republic*. While Plato conceived of the ultimate architecture of the ideal realm on the *mathematical* model, he distinguished the philosophical thinking he aimed at from *mathematics*, at least the mathematics as practiced by mathematicians of his time. Plato thought that only philosophy, and specifically dialectic, could achieve, for humans, the maximally close proximity to the ultimate architecture of (ideal) reality. He expressed doubts that mathematics as a technical discipline, or at least mathematicians could do so, given their (Pythagorean) attitude, too tolerant of the presence of the alogon with the logos of mathematics, however, circumvented this presence may be. According to S. Negropontis, citing the *Republic*:

> "But, surely," said I, "if you should ever nurture in fact your children whom you are now nurturing and educating in logos ("toi logoi"), you would not suffer them, I presume, to hold rule in the state, and determine the greatest matters, being themselves as irrational ("alogous") as the lines ("grammas"), so called in geometry." "Why, no," he said. ([*Republic*] 534d3-7)

> This is, not just a silly linguistic quip, as some Platonists think but a quite revealing passage that contrasts the philosophic "logos" to the geometric "alogoi" lines. According to the definition, which is due to Theaetetus and appears in Book X of the Elements, a line a is "alogos" (literally, "ratio–less") with respect to a given ("protetheisa") line b if a^2 and b^2 are incommensurable. (Negropontis 2019, p. 23)

Negropontis then argues that, while Plato adopted Theaetetus' mathematical *theory*, he also wanted to transfer it into dialectic so as to avoid the alogon (Negropontis 2019, p. 24). I leave aside technical details of this problematic, extensively

considered by Negropontis and other commentators. My point here is that ancient Greek thought appears to have contemplated or at least introduced the possibility of two forms of logos, Pythagorean and Platonist. The first is that of a logos inhabited by the alogon, and the second is that of a pure logos without the alogon in it and, in considering the first type, the aspiration of overcoming the alogon within a logos, an aspiration equally dominant in mathematics, physics, and philosophy throughout their history. I shall, accordingly, define Platonism as the aspiration toward a logos without the alogon. This definition allows me to bring most known forms of Platonisms together with that of Plato himself. They may be different on other grounds, including when, in contrast to Plato, it applies to matter, to the material constitution of physical reality, which may be seen as a form of idealism, an idealism of matter, insofar as it allows thought to fully capture this constitution. On the other hand, it is the possibility of a logos with the alogon within it that makes this chapter invoke Pythagoras' ghost of mathematical modernism, as against its "Plato's ghost," of Gray's title of his book on mathematical modernism (Gray 2007).

It is, again, a separate question whether any of the Pythagoreans ever embraced the first logos without aiming to overcome the alogon in it, which, as I said, appears unlikely. There is also a question of the scope of Pythagorean thinking concerning the relationships between the commensurable and the incommensurable even in mathematics itself and, especially, whether they extended the concept of a logos containing the alogon within it beyond mathematics, for example, to cosmology. I make no definitive claims as regard either case. My main concern here is the *spirit* of Pythagoras, defined by posing the problem of a logos containing the alogon within, in the subsequent history of mathematics and, then, beginning with Galileo and R. Descartes, mathematical physics, moreover, primarily during the modernist period, leading to our own time. On the other hand, it would, I think, be difficult to entirely rule out that some among the Pythagoreans or, philosophically, other pre-Socratics have contemplated this problem in this form, possibly on a cosmological scale, and even adopted a more positive attitude toward such as a logos. F. Nietzsche argued that such an attitude could be found, even apart from the discovery of the incommensurables, among the pre-Socratics during, in his terms (linked to the ancient Greek tragedy), "the tragic age of the Greeks," juxtaposed by Nietzsche to the Socratic age, defined by the aspiration to discover a logos without the alogon (Nietzsche 1996). One should still keep in mind that such claims reflect a modern reconstitution of ancient Greek thinking, especially in the case of the pre-Socratics, where we deal with fragmented texts, often via citations by later authors. It is also a separate question whether Plato had ever achieved his goal of establishing a philosophical logos free from the alogon in his texts, for they, too, sometimes work against the grain of this aspiration, as in his discussion of *khōra* in *Timaeus*, which could be read as more open to the alogon within the logos of philosophy (51a) (Derrida 1995).

2 The Spirit of Pythagoras: Geometry and Algebra – From Modernity to Modernism

While unavoidably invoking earlier developments, in particular, ancient Greek mathematics and the mathematics that emerged along with *modernity* (such as algebra, analytic geometry, and calculus), this chapter is primarily concerned with mathematical *modernism*, which took the center stage around 1900, building on several developments of nineteenth-century mathematics, and which extends to our own time. In this section I focus on the relationships between geometry and algebra in modernism and in radical Pythagorean mathematics. Their other, specifically epistemological, features will be discussed in the next two sections.

First, I shall define two general categories, modernity and modernism, in relation to which mathematical modernism will be positioned. Modernity is a broad cultural category. It refers to the period of Western culture extending from about the sixteenth century to our own time: we are still modern, although, during the last 50 years or so, modernity entered a new stage, postmodernity, shaped by the rise of digital information technology. Postmodernity, however, also amplified modernist epistemological trends, such as the role of the unthinkable in thinking, in art, philosophy, and mathematics and science (e.g., Lyotard 1984). Modernity is defined by several interrelated transformations, sometimes known as revolutions, although each took a while. Among them are scientific (defined by the new cosmological thinking, beginning with the Copernican heliocentric view of the Solar System, and the introduction of physics as the mathematical-experimental science by Descartes, Galileo, and Newton); industrial or, more broadly, technological (defined by the transition to the primary role of machines in industrial production and beyond); philosophical-psychological (defined by the rise of the concept of the individual human self, beginning with Descartes' concept of the Cogito); economic (defined by the rise of capitalism); and political (defined by the rise of Western democracies).

One might add to this standard list the mathematical revolution, rarely discussed as such, although sometimes considered as part of the scientific revolution. Although algebra was crucial to modern mathematics and physics, geometry remained dominant for a long time and has never lost its significance. Thus, while the laws of classical mechanics, embodied in its equations, are algebraic, they are grounded in geometrical picture of the world, including the motion of bodies, such as, paradigmatically, planets moving around the Sun. *Modern* geometrical thinking had continued to define physics, including relativity (although it has modernist aspects), until quantum mechanics (QM), which is more algebraic in character. As discussed below, QM has its geometry, too, which makes it Pythagorean on this account, alongside the radical Pythagorean character of its epistemology, defined by placing the ultimate constitution of nature beyond knowledge or even conception and thus by bringing the alogon into the logos of QM.

In contrast to modernity, "modernism" is a well-established denomination only when applied to literature and art. There, modernism refers to certain developments in the first half of the twentieth century, from roughly the 1900s on, represented by such figures as W. B. Yeats, J. Joyce, F. Kafka, R. M. Rilke, and V. Woolf, in

literature; P. Picasso, W. Kandinsky, and P. Klee, in art; and A. Schoenberg and I. Stravinsky in music. On occasion, it has been applied to the philosophy of the same period, such as that of Nietzsche, E. Husserl, and M. Heidegger. The denomination has been rarely used in considering mathematics and physics, or science, as opposed to "modern," used frequently, but with different periodizations. In mathematics, "modern" tends to refer to the mathematics that had emerged in the nineteenth century, with such figures as K. F. Gauss, H. Abel, A-L. Cauchy, and E. Galois, while in physics it refers to all mathematical-experimental physics, from Galileo and Descartes on, which uses the mathematics (algebra, analytic geometry, and calculus) developed around the same time. This is fitting because this physics emerged along with and shaped the rise of modernity making it scientific. After the discovery of relativity and quantum theory, the term "classical physics" was adopted for the preceding physics, still considered modern by virtue of its mathematical-experimental character. As Heidegger argued in commenting on Galileo and Descartes, "modern science is experimental because of its mathematical project" (Heidegger 1967, p. 93). I also adopt the designation "modern" for the mathematics emerging at the same time. If modernity is scientific, it is because it is also mathematical.

Arguably the most prominent recent example of using the term modernism in referring to mathematics is Gray's *Plato's Ghost: The Modernist Transformation of Mathematics* (2007), in part following (Mehrtens 1990). The book covers developments in *modern* mathematics (such as topology, set theory, abstract algebra, and rethinking the foundations of geometry) that had reached their *modernist* stage around 1900. It characterizes modernism arguably most essentially by the independence from relation to the object of nature, *physis*, and thus from physics, a feature difficult to deny to mathematical modernism (e.g., Gray 2007, p. 20). The book focuses, in considering this separation and beyond, primarily on geometry, with Hilbert's *Foundations of Geometry* (Hilbert 1999) as the conceptual center, analysis, and on post-Cantorian logical foundations of mathematics, where Hilbert, again, figures prominently. On the other hand, it somewhat marginalizes algebra, where this separation is more pronounced even during the modern period, and, with it, the Pythagorean character of modernism, as concerns both its mathematical architecture (defined by the interplay of geometry and algebra, also in analysis) and its epistemology, defined the alogon within its logos. As a result, Gray misses the ghost and, more importantly, the spirit of Pythagoras in mathematical modernism (the spirit that, as we have seen, has also inhabited the geometry of continuity from the Pythagoreans on), ultimately surrendering it to Plato's ghost, the ghost of a (geometrical) logos without the alogon.

Historically, just as modernist literature and art, modernist mathematics and science are characterized by major transformations. However, the complex and multifaceted nature of these transformations and their causes makes it difficult to uncontestably define their nature. It is hardly surprising, then, that, *conceptually*, the thinking concerning modernism in any field is diverse and, in each case, only partially reflects the nature of modernism in a given field or in the relationships among fields. This limitation cannot be avoided by this chapter either. Accordingly, I only argue that the form of modernist mathematics especially considered here,

radical Pythagorean mathematics, emerged coextensively with mathematical modernism but not that it exhausts it, let alone the development of mathematics during that period, not all of which is modernist by any definition of modernism. Radical Pythagorean mathematics has its history, too. For one thing, this mathematics is shadowed by the ghost of Pythagoras or, taking advantage of both the proximity of words "ghost" and "spirit" and a more creative meaning of "spirit," animated by the spirit of Pythagoras. The radical Pythagorean attitude, however, emerged or in any event became manifested during mathematical modernism, including in the way modernist mathematics functioned in physics. While, mathematical modernism is in part defined by its divorce from physics, modernist physics has never divorced itself from mathematics. Quite the contrary; it gave mathematics a greater and even unprecedented significance in physics. Indeed, ironically, modernist physics depends on mathematics that emerged as a result of this divorce.

Now, I understand algebra as the mathematical formalization of the relationships between symbols, arithmetic as the mathematical practice dealing specifically with numbers, geometry as the mathematical formalization of spatiality, especially in terms of measurement, and topology as the mathematization of the structure of spatial or spatial-like objects apart from measurements, through their continuity or discontinuity. The corresponding mathematical fields are algebra, number theory, geometry, and topology. Analysis deals with questions of limit, and related concepts, such as continuity, differentiation, integration, and so forth. There are multiple intersections between these fields, and fields that branch off these basic fields.

Defining algebra as the mathematical formalization of the relationships between symbols makes it part of all modern mathematics. The ancient Greek geometry was more self-contained, although one might detect elements of proto-algebraic symbolism there as well, especially at later stages of its development, as in Diophantus (third century AD), who shares the honor of "the father of algebra" with Muhammad ibn Mûsâ al-Khwârizmî (eighth to ninth century). Geometrical and topological mathematical objects always have algebraic components in their structure, while algebraic objects may, but need not, have geometrical or topological components. Two other meanings of algebra are important as well. The first, standing at the origins of algebra as a mathematical discipline, is that of algebra as the study of algebraic equations. The second is that referring to algebraic structures such as groups, which are crucial to geometry and topology. All these aspects of algebra are important to mathematical modernism, even in fields, like geometry and topology, that are disciplinarily juxtaposed to algebra. It is not only a matter of having an algebraic component as part of the mathematical structure of geometrical or topological objects but also of defining these objects algebraically.

An emblematic case of the role of algebra in modernist mathematics is algebraic topology. As part of topology, algebraic topology does have an earlier history, extending from G. Leibniz, with L. Euler as the main precursor before the rise of the discipline as such with B. Riemann, H. Poincaré, and others. General or point-set topology has a much longer history, extending to Plato and Aristotle, and possibly the Pythagoreans (e.g., Thom 1988; Papadopoulos 2019). What makes algebraic topology a mathematical discipline is the fact that one can associate algebraic

structures (initially numbers, eventually groups and other abstract algebraic structures) to the architecture of spatial objects that are invariant under continuous transformations, independently of their geometrical properties, associated with measurements. This makes topology topo-*logy* vs. geo-*metry*. In retrospect, topology is inherently categorical. It relates, functorially, the objects of topological and algebraic categories, a form of algebraic thinking that is one of the culminating concepts of modernism, for example, in A. Grothendieck's algebraic geometry. While keeping in mind this defining difference between topology and geometry, I shall for the purposes of this article group them together under the rubric of geometry as the mathematical science of spatiality, in juxtaposition to algebra as the science of mathematical symbolization.

Is, then, modernist geometry, a form of algebra? It is tempting to argue such a case, and the present author has done so previously, even if in a qualified way (Plotnitsky 2018, 2019b). Here, however, I would like to take a more nuanced view and consider, on Pythagorean lines, the *irreducible* interplay of geometry and algebra in modernist mathematics, an interplay that is underlain by that which is neither, any more than anything else we can conceive of, by the alogon within the logos of mathematics.

Even at the most immediate level, geometry has retained its significance in modernism on several counts, two of them in particular. First, the algebra defining modernist geometrical and topological objects has a special form that may be called "spatial algebra." Spatial algebra arises from algebraic structures that *mathematically* define geometrical or topological objects and reflects their proximity to $\mathbf{R}^3$ and mathematical spatial objects there that are close to our phenomenal intuition. This proximity may be, and commonly is, left behind in rigorous mathematical definitions and treatments of such objects, beginning with $\mathbf{R}^3$ itself. The same type of algebra may also be used to define mathematical objects that are no longer available to our phenomenal intuition. Among examples of such objects are a projective line (a set of lines through the origin of a vector space, such as $\mathbf{R}^2$, with projective curves defined algebraically, as algebraic varieties) and an infinite-dimensional Hilbert space (the points of which are typically square-integrable functions or infinite series, although a Euclidean space of any dimension is technically a Hilbert space, too). Spatial algebra is an algebraization of spatiality that makes it rigorously mathematical, topologically or geometrically, as opposed to something that is phenomenally intuitive spatially, even in the case of more conventional spatial objects in $\mathbf{R}^3$.

In addition, which is the second count on which spatial algebra retains its connection to geometrical thinking, analogies with $\mathbf{R}^3$ continue to remain useful and even indispensable. Thus, the analogues of the Pythagorean theorem or parallelogram law in Euclidean geometry, which holds in infinite-dimensional Hilbert spaces, are important, including in applications to physics, especially QM, the formalism of which is based in Hilbert spaces over $\mathbf{C}$. Indeed, our *thinking* concerning geometrical and topological objects is not entirely translatable into algebra. This was well understood by Hilbert in his axiomatization of Euclidean geometry, although this axiomatization clearly had a spatial-algebraic character (Hilbert 1999). According to D. Reed:

> [A]fter a chapter in which [Hilbert] provides himself with more tools to link geometry and algebra [following Descartes' analytic geometry], he goes on to demonstrate in a truly spectacular way:
>
> (*) a "theory of plane area can be derived from the axioms" (but not a theory of volume);
> (*) Desargues' theorem, which states that if two triangles are situated in a plane so that pairs of corresponding sides are parallel then the lines joining the corresponding sides pass through one and the same point or are parallel . . ., expresses a criterion for a "plane" geometry to form part of "space" geometry; and
> (*) Pascal's theorem [technically the affine version of Pascal's theorem], which states that if A, B, C, and A^I, B^I, C^I are two sets of points on two intersecting lines and of AB^I is parallel to BC^I and AA^I is parallel to CC^I then BA^I is parallel to CB^I . . . is dependent in a very specific way on the so-called Axiom of Archimedes.
>
> None of these statements can be given a simple unequivocal expression in the realm of algebra even though models from 'analytic geometry' are used in the demonstrations. In other words, while algebra is useful as a tool in the demonstration of geometrical statements it is not useful in formulating the statements themselves. (Reed 1995, pp. 33–34)

While Reed is right to stress the significance of geometrical thinking and expression in mathematics, his claim that algebra is not useful in formulating geometrical statements is a simplification even in Euclidean geometry, where our geometrical intuition is more applicable and where certain proofs could be purely geometrical. Besides, a more natural setting for Desargues' and Pascal's theorems is projective geometry, which these theorems helped to usher in, a setting that we cannot visualize and that is spatial-algebraic.

One can gain further insight into this situation by considering the principle due to J. Silverman and J. Tate: "Think Geometrically, Prove Algebraically!" It was introduced in their book on "the rational points of elliptic curves" (a modernist subject):

> It is also possible to look at polynomial equations and their solutions in rings and fields other than **Z** or **Q** or **R** or **C**. For example, one might look at polynomials with coefficients in the finite field $\mathbf{F}_p$ with p elements and ask for solutions whose coordinates are also in the field $\mathbf{F}_p$. You may worry about your geometric intuitions in situations like this. How can one visualize points and curves and directions in $\mathbf{A}^2$ when the points of $\mathbf{A}^2$ are pairs (x, y) with $x, y \in \mathbf{F}_p$? There are two answers to this question. The first and most reassuring is that you can continue to think of the usual Euclidean plane, i.e., $\mathbf{R}^2$, and most of your geometric intuitions concerning points and curves will still be true when you switch to coordinates in $\mathbf{F}_p$. The second and more practical answer is that the affine and projective planes and affine and projective curves are defined *algebraically* in terms of ordered pairs (r, s) or homogeneous triples $[a, b, c]$ without any reference to geometry. So in proving things one can work algebraically using coordinates, without worrying at all about geometrical intuitions. We might summarize this general philosophy as: *Think Geometrically*, *Prove Algebraically.*" (Silverman and Tate 2015, p. 277)

Affine and projective planes and curves can in principle be defined without any reference to our phenomenal intuition, which grounds the geometrical thinking Silverman and Tate refer to, rather than spatial algebra, which defines them rigorously.

Even in these more intuitively accessible cases, we think algebraically, too, by using spatial algebra, except possibly in dealing with low-dimensional topological and geometrical objects, where topological and geometrical arguments could be used more rigorously. I would argue, however, that spatial algebra is still irreducible there because one commonly converts topological operations into algebraic ones. This conversion, in low dimensions, was essential to the origin of algebraic topology. On the other hand, the more recent development of low-dimensional topology, following, among others, W. Thurston's pioneering work from the 1970s on, is a geometrically oriented trend that counters modernist algebraization but only to a degree, because the algebraic structures associated with these objects remain crucial. Some of the most powerful algebraic tools of algebraic topology have been used and even developed in this field. It is also true that a mathematician can develop and use intuition in dealing with discrete geometries, say, that of the Fano plane of order 2, which has the smallest number of points and lines (seven each). However, beyond the fact that they occur in the two-dimensional regular plane, the diagrammatic representations of the Fano plane are still difficult to think of as other than spatial algebra, in this case combinatorial. Euclidean intuitions are limited even when we deal with algebraic curves in the Euclidean plane, let alone in considering curves and other objects of finite or projective geometries, abstract algebraic varieties, Hilbert spaces, the spaces of noncommutative geometry, or geometric groups, a great example of the extension, by a reversal, of spatial algebra to algebraic objects as such.

And yet, these geometrical intuitions and, thus, geometry are indispensable. Silverman and Tate's "*think* geometrically" may even be read as giving geometry a greater creative significance, although proving theorems requires thinking, too. Our geometrical thinking shapes our practice of spatial algebra and other areas of abstract algebra, for example, when dealing with such objects as ideals of rings, even apart from algebraic geometry where manifolds or schemes are constructed of ideals (maximal or prime, respectively) of commutative rings. For the moment, however, I would like to emphasize the creative role of intuitive geometrical *thinking*, which may need algebra to achieve the necessary mathematical rigor – Prove algebraically! – but is crucial to mathematical thought as geometry – Think geometrically!

3 Radical Pythagorean Mathematics and Mathematical Modernism

Both defining features of radical Pythagorean mathematics – the reciprocal interplay of geometry and algebra (and the modernist rethinking of each) and mathematical thinking inhabited by the unthinkable, a mathematical logos inhabited by the alogon – are, I argue, found, often working together, in mathematical modernism and modernist physics, especially quantum theory. These features are, however, rarely, if at all, addressed in discussions of mathematical modernism (whether the term is used or not), perhaps because the idea of the role of the unthinkable as an enabling condition of thinking is as resisted by commentators on mathematical modernism as by most mathematicians and physicists. As noted, arguably the most prominent aspect of

mathematical modernism in these discussions is mathematics' capacity for an independence from its relation to nature and thus from physics and, in part correlatively, from our daily phenomenal intuition and concepts, in sum, a fundamentally abstract character of modernist mathematics. While these features are difficult to deny to mathematical modernism, the latter, I argue, has accomplished quite a bit more, including in physics, not the least by its Pythagorean and ultimately radical Pythagorean nature.

According to Gray, referring what he calls "the crisis of continuity": "This is the widespread feeling among mathematicians around 1900, documented in many sources, that the basic topic of analysis, continuity, was profoundly counterintuitive. This realization marks a break with all philosophy of mathematics that present mathematical objects as idealizations from natural ones: it is characteristic of modernism" (Gray 2007, p. 20). Given Gray's overall argument, "natural" here refers to both objects of nature and common objects of our daily phenomenal intuition, which can also be related to each other, as they are in classical physics or in daily life. While Gray's claims here are valid, they require qualifications. First of all, mathematics separated, abstracted, itself from representing natural objects and thus from physics, and even from our daily phenomenal world much earlier, already with the Pythagoreans, or during modernity, with the rise of algebra, especially the study of algebraic equations, pursued largely apart from physics. It is true, however, that both geometry and analysis had kept close relationships with representing nature and thus physics and also with our daily thinking and its representation of nature, a representation that classical physics refines and mathematically idealizes, including by using geometry and calculus. It is also easier to argue this type of case in its disciplinary and institutional sense, insofar as the possibility of this separation was used to ground the disciplinary field of mathematics from modernity to modernism. The drive toward this independence had been emerging in *modern* mathematics from the 1800s on, but with the rise of mathematical modernism, it reached the stage of breaking with representing (mathematically idealizing) natural objects in most areas of mathematics, including geometry and analysis, especially following the rise of set theory and G. Cantor's investigations of the nature of mathematical infinity and his continuum hypothesis. Cantor's set theory was a major and, in some respects, the most significant event in the history of "the crisis of continuity" invoked by Gray, and it separated the nature of continuity in mathematics from our phenomenal intuition of continuity especially radically and irrevocably. Quantum theory, beginning with M. Planck's discovery of it in 1900, was about to contribute to this crisis as well, in QM by way of complex relationships between mathematical continuity and physical discontinuity, discussed below.

This double divorce of modernist mathematics from both the representation of natural objects and our general phenomenal intuition was stressed by H. Weyl, himself a major figure of mathematical modernism, half a century earlier. Weyl made this point in his 1918 *The Continuum* (Weyl 1928), followed closely by his 1918 classic *Time Space Matter* (Weyl 1952), both shaped by modernist mathematics, by which point quantum theory (not yet QM) enters his thinking concerning continuity and its role in physics (Weyl 1952, p. 23). According to Weyl: "the

conceptual world of mathematics is so foreign to what the intuitive continuum presents to us that the demand for coincidence between the two must be dismissed as absurd" (Weyl 1928, p. 108). "Coincidence" is, however, not the same as "relations," which are unavoidable, at least insofar as it is difficult to think of continuity spatially apart from our phenomenal intuition. On the other hand, it is possible to define the continuum algebraically. This situation, as just noted, emerged with Cantor's introduction of set theory and, with it, the multiplicity of infinities, the infinity of infinities, and his continuum hypothesis. It was made more dramatic by Gödel's incompleteness theorems of 1931 and then P. Cohen's proof of the undecidability of the continuum hypothesis in the 1960s. These findings made us realize not only that we do not know but also and more radically that we *cannot know* how a continuous line, straight or curved (which does not matter topologically), is constituted by its points.

Weyl's overall point pertains to most of modernist mathematics. Physics, such as relativity and quantum theory, was able to take advantage of this divorce between mathematics and our general phenomenal intuition. Weyl added to his statement cited above: "Nevertheless, those abstract schemata supplied us by mathematics must underlie the exact sciences of domains of objects in which continua play a role" (Weyl 1928, p. 108). This comment was made primarily with Einstein's relativity in mind, as Weyl's next book, *Time Space Matter*, was already in the works. This view retains a modernist twist because the *abstract* schemata used in relativity and then QM are divorced from our phenomenal intuition. Both used modernist mathematics, respectively, that of Riemannian geometry and that of infinite-dimensional Hilbert spaces, but with a crucial difference, in part due to the fundamental role of discontinuity in QM, even though both cases deal with continuous mathematics and in fact geometry.

Relativity still did this in a realist way. This is possible, because the break from our phenomenal intuition need not entail a divorce from realism or ontology, even a physical one, let alone mathematical, which is possible in the absence of a physical ontology, including in QM. Relativity was a radical departure from classical physics because the relativistic law of addition of velocities (defined by the Lorentz transformation) in special relativity, $s = \frac{v+u}{1+(vu/c)^2}$, for collinear motion ($c$ is the speed of light in a vacuum), runs contrary to any possible intuitive representation. This concept of motion is, thus, no longer a mathematical refinement of a daily concept of motion as the classical concept of motion is. Relativity was the first physical theory that defeated our ability to form a phenomenal conception of an elementary individual physical process. It was a form of incommensurability, in this case between nature and our phenomenal intuition, rather than in any mathematical sense. The theory, however, still allowed for a mathematized representation of physical reality.

By contrast, QM, at least in certain nonrealist interpretations (defined below as reality-without-realism, RWR, interpretations), only used mathematics for providing probabilistic or statistical predictions concerning the outcomes of quantum experiments, without providing a representation of the ultimate constitution of what is

responsible for these events, even a purely mathematical one in the absence of a physical one. (The latter view has been entertained, including by Heisenberg in his later work.) These probabilistic predictions are, moreover, only possible by using ad hoc rules *added* to the formalism rather than being part of it, such as Born's rule, which relates, by using complex conjugation, complex quantities of the QM formalism (the so-called amplitudes) to real numbers corresponding to the probabilities of quantum events. One takes the square moduli of the eigenvalues of the operators associated with quantum variables, such as position, momentum, or energy (or equivalently, multiply these eigenvalues by their complex conjugates), which gives one real numbers, corresponding, once suitably normalized, to the probability densities of observed events. In departure from the classical probability theory, the rule for adding the probabilities of alternative outcomes is changed to first adding the corresponding amplitudes and deriving the final probability by squaring the modulus of the sum by Born's rule. Accordingly, in these interpretations, QM used "abstract schemata" of modernist mathematics in a radically new way and established a new type of relationships between the mathematics of a physical theory and the experimental data considered.

Representations and the corresponding physical ontologies are possible and necessary in dealing with some strata of reality considered in QM, specifically, that observed in measuring instruments, defining, in Kant's language, *quantum phenomena*. Let's call this reality Reality A. On the other hand, a knowledge or even conception of the ultimate nature of reality responsible for quantum phenomena corresponding to or idealized as, in Kant's language, quantum *objects*, and thus the ultimate-level ontology are no longer offered. (As will be seen presently, this view of quantum objects goes beyond Kant.) Let's call this reality Reality X. Importantly, the existence of Reality X is, rather than merely assumed, *inferred* from the effects it has on Reality A. To use a mathematical metaphor, X is defined by the conceptual equation $f(\mathrm{X}, \mathrm{A}) = 0$ (with f symbolically standing the sum of the conditions of quantum experiments), which has a "solution" that cannot, however, be represented in terms of A and is irrational relative to A, even though effects of Reality X on Reality A can be probabilistically predicted by QM, which makes the relationships between A and X strictly mathematical. We neither know nor can even conceive how these relationships are physically possible. Reality X is thus *constructed by thought* as *unconstructible by thought*, at least as things stand now, analogously to the way the incommensurables (irrationals) were constructed by Pythagorean arithmetic, in this case literally as (in our terms) a solution of the equation $X^2 - 2 = 0$. If one adopts the radical Pythagorean view, this situation is assumed to be an enabling condition of thought and knowledge, rather than inhibiting both, with a hope to be eventually overcome, as it happened in Pythagorean geometry.

This view may also be designated "the reality-without-reality (RWR) view," the language introduced by the present author previously (e.g., Plotnitsky 2016, 2018, 2019a, b). Reality X exists, is *real*, and has effects on Reality A but allows for no representation or even conception, as would be required by realism. Although the RWR epistemology is the same as that of the radical Pythagorean view, the RWR view is more general: it does not depend on the relationships between algebra and

geometry that co-define the radical Pythagorean view, and it can apply beyond mathematics and physics, for example, in other sciences or in philosophy.

While one can, thus, trace the history of the RWR view to the Pythagoreans and their discovery of the alogon within the logos of arithmetic, its modern history may be argued to have originated with Kant's philosophy, which distinguished noumena as objects or things-in-themselves and phenomena or representations in our thought (Kant 1997). It was, however, expressly introduced in physics with QM, beginning with Heisenberg's discovery of the theory (Heisenberg 1925) and Bohr's interpretation of it, developed, with some significant revisions over two decades and presented in several articles. According to Bohr, in QM we are no "longer in a position to speak of the autonomous behavior of a physical object, due to the unavoidable interaction between the object and the measuring instruments" (Bohr 1937, p. 79). Hence, as he said elsewhere, "in quantum mechanics, we are not dealing with an arbitrary renunciation of a more detailed analysis of atomic phenomena, but with a recognition that such an analysis is *in principle* excluded" (Bohr 1987, vol. 2, p. 62). The RWR view, in its most radical form, is, however, different from that of Kant. While Kant places things-in-themselves (objects) beyond representation or knowledge (phenomena), he still allows that a *conception* of them could be formed and even be true, although this truth cannot be guaranteed (Kant 1997, p. 115).

What is, however, the difference between placing the ultimate nature of the reality, physical or mathematical, beyond representation or knowledge and placing it beyond conception? For, if, as Bohr says, we are "not . . . any longer in a position to speak of the autonomous behavior of a physical object," would not this already imply that this behavior, or again, the RWR-type of reality so idealized, is beyond conception? For, if we had such a conception, would we not be able to says something about it or represent it? The situation is not so straightforward. First, there is difference between *some* conception of this reality and a theory that would enable us to provide a representation, especially a mathematized one. Bohr, however, makes a stronger claim: we are no longer in a position to *speak* of the autonomous behavior of quantum objects or the reality thus idealized *at all* and, thus, it follows, to have a conception of this reality. The question then becomes that of whether our inability to do so only characterizes the quantum-mechanical situation as things stand now (A) or reflects that this reality is beyond the reach of our thought altogether, ever (B), a view adopted by the present author (Plotnitsky 2016, 2018, 2019a, b). While Bohr, thus, at least assumes (A) and while there are signs that he might have entertained (B), he never stated so, which leaves whether he assumed (B) open to interpretation. Logically, once (A) is the case, then (B) is possible. I am not saying that (B) is necessary but only that it is *possible*. There does not appear to be any experimental data so far compelling one to prefer either (A) or (B). Both views are thus far equivalent as far as physics is concerned. But they are different philosophically in defining how far our thought could, in principle, reach in investigating the ultimate constitution of nature.

The qualification "as things stand now," however, applies to (B) as well, even though it might appear otherwise given that this view precludes any conception of

the ultimate reality not only now but also ever. It still applies because a return to realism, to a logos without the alogon, is possible on experimental or theoretical grounds. This return may take place either because quantum theory, as currently constituted, is replaced by an alternative theory that allows for a realist interpretation, or because (B), or (A), becomes obsolete even for those who hold it and is replaced by a realist view with QM or QFT in its present form. It is also possible, however, that either (A) or (B) will remain viable in interpreting of QM or quantum field theory (QFT), which handles high-energy quantum physics, where this view equally applies, and thus all quantum physics as currently constituted and experimentally confirmed (Plotnitsky 2019b).

As noted from the outset, the epistemological cost of the radical Pythagorean or RWR view is not easily absorbed and to some, beginning again with Plato, or the Pythagorean themselves, and then Einstein, is unacceptable. This is not surprising, because this view defies many basic assumptions concerning the workings of nature and thought. These assumptions, in part arising due to the neurological constitution of our brain, have served us for as long as human life itself, and within certain limits are unavoidable, including in physics, although, while respected by classical physics, they were, as noted, already challenged by relativity. QM made this challenge much greater, without entirely renouncing these features, which are applicable at levels other than that of the ultimate constitution of nature, specifically in describing measuring instruments.

In QM, the RWR view arises by virtue of the algebraic rather than, as in classical physics or relativity, geometrical, relationship between the mathematics of a physical theory and physical reality in its ultimate constitution, Reality X. This shift compelled Einstein to speak of "the Heisenberg method" as fundamentally algebraic (Einstein 1936, p. 378). Indeed, as just explained, "the Heisenberg method" established new, mathematically algebraic and epistemologically irreducibly probabilistic, relationships between a (mathematized) physical theory and nature. It is worth nothing in this connection that probability theory is, too, essentially algebraic. The origin of probability theory, in the work of G. Cardano, B. Pascal, and P. Fermat coincides with the emergences of algebra. As I. Hacking argued in explaining why the theory emerged in the seventeenth century rather than earlier, some form of algebra was necessary for probability theory (Hacking 2006). QM, however, reshaped, on RWR lines, how probability works, as against previous uses of probability, for example, in classical statistical physics. There the relationships between them is underlain by a geometrical picture of the behavior of the individual constituents of the systems considered, assumed to follow the laws of classical mechanics. By contrast, in quantum physics, even the behavior of the elemental individual quantum objects too had to be treated probabilistically.

In confronting this situation, Heisenberg was compelled to conceive of QM, on RWR lines, as theory designed only for predicting the probabilities of what was observed in measuring instruments, as quantum phenomena (Reality A), without representing the behavior of quantum objects, even the elementary ones (Heisenberg 1925). Quantum objects were or, more precisely, idealized Reality X. Even before his paper was published he said: "What I really like in this scheme is that one can really

reduce *all interactions* between atoms and the external world … *to transition probabilities*" between quantum measurements (Heisenberg, Letter to Kronig, 5 June 1925; cited in Mehra and Rechenberg 2001, vol. 2, p. 242; emphasis added). The "scheme" worked! It was Heisenberg's renunciation of a geometrical representation of quantum objects and behavior by replacing the geometry of trajectories with the algebra of probabilities that led him to the discovery of QM. (QM was co-discovered by E. Schrödinger by using a realist approach, while, however, still at least allowing for an RWR-type interpretation.)

Heisenberg used and in fact reinvented mathematics never previously used in physics, in essence (although Heisenberg did not present it in these terms) that of infinite-dimensional Hilbert spaces over **C**. A radically new, for physics, feature of his algebra was the noncommutative nature, $PQ - QP \neq 0$, for the corresponding physical variables, Hermitian operators in Hilbert spaces over **C** (replacing the functions of real variables of classical mechanics), for example, and in particular, those associated, respectively, with the momentum, P, and the coordinate, Q. This feature proved to be momentous. Most famously, it came to represent in the formalism of QM, Heisenberg's uncertainty relations making impossible simultaneous measurements or predictions for the momentum (P) and the coordinate (Q) *associated* with a quantum object (but observed only in measuring instruments), the impossibility defined by Bohr as "complementarity." While unbeknownst to Heisenberg, who reinvented it, noncommutativity was, however, a familiar feature of mathematics by then and may indeed be seen as part of mathematical modernism.

Heisenberg's approach or "method" was, thus, grounded in the primacy of algebra, as against classical physics and relativity or the preceding quantum theory, specifically, Bohr's 1913 atomic theory, which retained a geometrical, orbital, representation of electrons' motion in so-called stationary states, although it renounced any conception of transitions between such states. The algebraic nature of the theory was, again, emphasized by (and worried) Einstein:

> [P]erhaps the success of the Heisenberg method points to a purely algebraic method of description of nature, that is, to the elimination of continuous functions from physics. Then, however, we must give up, in principle, the space–time continuum [at the ultimate level of reality]. It is not unimaginable that human ingenuity will some day find methods which will make it possible to proceed along such a path. At present however, such a program looks like an attempt to breathe in empty space. (Einstein 1936, p. 378)

The theory has, however, proven to be extraordinarily successful, and it remains our standard theory of quantum phenomena in both low- and high-energy quantum regimes, governed by QM and QFT, respectively. Quantum electrodynamics (QED), which is part of QFT, is the best experimentally confirmed physical theory ever. Quantum theory is, however, "not a *description* of nature," because, in the RWR view, it offers no representation of the ultimate constitution of nature, which was Einstein's imperative for a fundamental theory and to which he referred here.

A few qualifications are in order, which will also bring geometry back into quantum theory. First, in saying that "we must give up, in principle, the space–

time continuum," Einstein must have had in mind giving up the spacetime continuum in *representing* the ultimate reality considered. This view defined his philosophy of physics, embodied in general relativity, which was based in Riemannian geometry and, thus, the concept of continuous, actually differential, manifolds. The idea that this reality may ultimately be discrete had been around for quite a while by then. It was proposed as a possibility by Riemann as early as 1854 (Riemann 1854, p. 33). The idea has acquired new currency in view of QM and then QFT and was advocated by, among others, Heisenberg in the 1930s and is still around. In the RWR view, the ultimate nature of physical reality is beyond representation and even conception and, as such, may not be seen as either continuous or discrete. Discreteness only pertains to quantum phenomena, observed in measuring instruments, while continuity has no physical significance at all. It is, however, a feature of the formalism of QM, which thus relates to discrete phenomena by predicting the probabilities or statistics of their occurrence by means of continuous mathematics – a radically new form of the relationships between the continuous and the discrete in physics.

This situation also gives a greater complexity and geometry to the algebraic method of QM. It is true that the continuous functions (over **R)** used in classical physics or relativity (for variables such as position or momentum) are replaced by operators and their algebra in Hilbert spaces over **C**. Hilbert spaces open the possibility, amply used by physicists, to think geometrically. Besides, some continuous functions are retained, because these Hilbert spaces are those of continuous functions, considered as infinite-dimensional vectors in dealing with continuous variables such as position and momentum, although these variables themselves are, again, represented by operators. These functions, vectors, are those of complex (rather than, as in classical physics, real) variables, and the vector spaces that they comprise or associated objects, such as operator algebras, have special properties, such as noncommutativity. As noted, these vectors, of which Schrödinger's wave function, ψ, is the most famous example, play an essential role in calculating (via Born's rule) the probabilities of the outcomes of quantum experiments.

The ultimate nature of reality in QM, in RWR-type interpretations, Reality X, idealized by quantum objects may thus be seen as a form of "irrationality," the term invoked by Bohr, in the sense of its incommensurability with our concepts, physical, mathematical, and philosophical, which we use in quantum theory in considering Reality A, that of observed quantum phenomena. The situation exhibits a parallel with the case of the diagonal of the square in Pythagorean mathematics, especially given that our relationships to Reality X in QM are strictly mathematical. The parallel merits a further elaboration as an instructive case of the Pythagoras's ghost in, and Pythagoras's spirit of, modernist mathematics and physics. Bohr's invocation of "irrationality" in this connection is often misunderstood and, as a result, sometimes held against him. This irrationality not any irrationality of QM, of which Bohr expressly speaks as a "rational" theory (Bohr 1987, vol. 1, p. 48). Bohr's use of "irrationality" is based on an analogy with irrational numbers, reinforced by the role of complex numbers and specifically the square root of -1, i (an irrational magnitude in the literal sense because it cannot be presented as a ratio of two integers) in

the formalism of QM (Bohr 1987, vol. 1, p. 76), while everything that we can actually observed is represented in terms of real, indeed, technically, *rational*, numbers. The deliberate nature of this analogy is confirmed by the fact that Bohr expressly reflected on this connections between the mathematical and quantum-theoretical concepts of the irrational, via the idea of a Riemann surface (which was part of the genealogy of his concept of complementarity) in his final interview (Plotnitsky 2017, p. 1130). On the other hand, the ultimate nature of the reality considered cannot be represented at all. The Pythagoreans' incommensurables must have been on Bohr's mind, not the least because in both cases one deals with the problem of measurement, with the mathematics and physics of *measurement*. QM offers no longer either algebraic (in parallel with the arithmetic of the Pythagoreans) or (in contrast to the post-Pythagorean Greek geometry) geometrical means of representing this irrationality. One can only, by using the geometry of Hilbert spaces (over **C**!), relate, probabilistically, to its effects upon what is observed in measuring instruments, as Reality A impacted by Reality X. The irrationality is that of the unrepresentable or inconceivable nature of the ultimate constitution of reality (idealized as quantum objects), while the "geometry" is that of a Hilbert space. Although this geometry no longer represents the incommensurable (the alogon), it still relates to it by means of an algebra of probability, which is possible only because of the relationships between the geometry and algebra of a Hilbert space. This is the logos of QM, which, in the spirit of the Pythagoreans, elevated to the radical Pythagorean thought, contains the alogon within it.

In ancient Greek mathematics, the problem was resolved geometrically by a new theory of proportion, accommodating both commensurable and incommensurable magnitudes. The arithmetical problem was only resolved, by essentially modernist means (algebra played a major role), in the nineteenth century, after more than 2000 years of effort, with Dedekind and others, albeit in view of the undecidability of Cantor's continuum hypothesis, resolved as ultimately unresolvable. It remains to be seen whether quantum-mechanical "irrationality" will ever be resolved by discovering a way to represent quantum objects and behavior, or the reality they idealize, Reality X, in which case this idealization will need to be replaced by a new one.

As things stand now, QM is a *rational* theory of something that is *irrational* in the sense of being inaccessible to a representation or knowledge, or even to thought. QM was a replacement of a *rational representational* theory, classical mechanics, with a *rational probabilistically or statistically predictive* theory (Bohr 1987, vol. 1, p. 48). QM is both a reversal of what happened in the crisis of the incommensurable in ancient Greek mathematics, which compelled it to move from arithmetic to geometry, in their theory of measurement, and a new form of the relationships between geometry and measurement, which relates a mathematical continuity to a physical discontinuity in terms of probabilities. "Thought . . . is the measure of the Universe," the greatest gift of Prometheus, the first Pythagorean, and the highest form of measurement, P. B. Shelley says in *Prometheus Unbound* (II, iv. 73). The phrase echoes Protagoras's "man is the measure of all things" but gives it the Pythagorean

meaning of a logos that must contain the alogon within it, because, as the poem says a few lines later, "the deep truth is imageless" (II, iv. 116).

4 The Thinkable, the Unthinkable, and the Real in Mathematics and Radical Pythagorean Mathematics

Analogous, even if not identical, situations to the one just considered in physics are found in modernist mathematics, in both Pythagorean aspects – the RWR nature of the ultimate reality, the alogon in a logos, and the Pythagorean interplay of geometry and algebra. For example, and in particular, this type of situation arises with Cantor's set theory, although it has been rarely, if ever, considered as such in the philosophy of mathematics, even following Gödel's incompleteness theorems of 1931 and then Cohen's proof of the undecidability of the continuum hypothesis in 1960s, which invite such a consideration. The nature of mathematical reality has of course been debated since the pre-Socratics, including the Pythagoreans, and it was at stake in Plato, whose ghost has overshadowed this debate in modernist mathematics, along with and against the ghost and the spirit of Pythagoras. As discussed from the outset, Plato responded to this thought by his attempt to overcome the alogon within the logos of philosophy, if not that of mathematics, leaving the task of this overcoming to mathematicians, who have attempted to do so ever since. The twentieth- and twenty-first-century philosophy of mathematics and mathematical logic have continued this project. Thus, mathematical Platonism (a twentieth-century philosophical trend, which should be distinguished from Plato's thought) assumes the existence of mathematical reality as independent of our thinking, which, however, could represent this reality, at least in principle. This view has been debated in turn, and several alternative, if sometimes intersecting, positions have emerged since and some before, such as logicism, formalism, intuitionism, conventionalism, and constructivism. I shall not enter these debates, apart from noting that the question of the domain, "location," of this reality has never been adequately answered by mathematical Platonists. It is difficult to think of that which is not material and yet is outside human thought, unless it is divine, which, however, is not a common assumption among mathematical Platonists. By contrast, I assume the reality of human thought, different for each of us, as the only domain in relation to which one can speak of the reality of mathematical objects and concepts, in juxtaposition to the material reality of nature considered in physics. It is possible to assume that the Platonist mathematical reality is a potentiality – the same, even if multiply branched, potentiality – in principle realizable by human thought. I shall comment on this possibility below.

What could be claimed to exist in our thought without much controversy are mathematical specifications, from strict definitions to partial and indirect characterizations, implying more complete future specifications. Such specifications would involve concepts, structures, logical propositions, or still others elements, which could be both geometrical and algebraic in the broader sense of these terms adopted here. The question, then, becomes whether anything else exists in our thought

beyond such specifications and the local ontologies they define, at least in our conscious thought, because we can unconsciously think of other properties of a given object or field, which may either be eventually made conscious or never become conscious and thus known. This qualification does not, however, change the nature of the situation, because one could either claim that the unconscious could only contain such specifications or that the object or broader reality in question, as different or exceeding such specifications, somehow exists there. Hence, essentially the same alternative remains in place. Some unconscious specifications may never become conscious. It is possible that some mathematics, even very great mathematics, just as poetry, never left the unconscious and there are accounts by mathematicians or poets of dreaming of mathematics or poetry which could not be remembered as what it actually was, although sometimes it can. Only our memory of dreams is conscious but never dreams themselves. Whatever is in our unconscious can, however, enter our consciousness. Our unconscious does a great deal of mathematical thinking, as it does most of our thinking in general, and some of this thinking may never be realized by our conscious thought. Sometimes, not uncommonly in the logical foundations of mathematics (Hilbert held this view), the consistency of a given definition of a mathematical entity is identified with the existence of the corresponding object, which becomes a form of mathematical Platonism, if this existence is assumed outside human thought.

My assumption here is that nothing mathematical exists beyond what can be thus specified by thought, possibly, again, in one's unconscious. This differentiates the situation from that of quantum theory in the RWR view. While quantum phenomena or quantum theories are specified by thought, one *assumes* the existence ofan ultimate physical reality, which is, in the RWR view, beyond representation or even conception and thus specification. By contrast, in the present view, even if some ultimate mathematical reality may be shared, it cannot be assumed to exist independent of thought; only physical matter in its ultimate constitution is assume to exist in this independent way. This assumption has been challenged as well, even by denying that the ultimate reality is material rather than mental, with Plato as the most famous ancient case (under the assumption, however, that this reality is unique and could be shared, just as the material reality in physics is now) and Bishop Berkeley as the most famous modern case. Still this is a common assumption in modern philosophy of physics, although assuming this reality to be beyond representation or even conception, now or especially ever, is uncommon. As just noted, it is possible that there are (mentally) real things that exist in our unconscious that will never become conscious. It is equally possible, however, that they will enter our consciousness at one point or another. The ultimate constitution of nature, in an RWR-type interpretation, is not assumed to become available, at least as things stand now, and possibly ever.

Our mathematical specifications could be made more complete or modified by new concepts, structures, and logical propositions, which would change the objects or concept in question, as say, a Riemann surface, as it developed during over, by now, a long period. However, in the present view, it is no longer possible to see such changes as referring to the same mathematical object (which can, again, be a broad

and multiple entity), approached by our evolving concepts. Instead, they create new objects or concepts. Thus, new multiplicities of Riemann surfaces are created by each modification of the concept. There are no Riemann surfaces as such, existing by themselves and in themselves; there is only what we can think about them at a given point of time. This view of mathematical reality has thus a constructivist flavor, in part following Kant's view of mathematics as the synthetic construction of mathematical concepts by thought (Kant 1997). (I use the term "constructivist" more generally, rather than referring to the trend known as "constructivism" in the foundational philosophy of mathematics, from intuitionism on, relevant as it may be, in part given Kant's influence.). Mathematics is only what can actually be thought, created by (conscious or unconscious) thought, and then expressed, communicated, and so forth, thus in accord with the Greek meaning of *máthēma* as that which can be known and learned, or taught.

It is not uncommon to encounter a situation in which a mathematical entity that cannot be given, now or possibly ever, an adequate mathematical specification, and is only specified partially mathematically or otherwise (e.g., by means of philosophical concepts), but that could only be consistently related to, indirectly, by means of a more properly specified mathematical concept or set of concepts. In the present view, however, any mathematical entity can only be seen as existing or real if it is sufficiently specified in some way, possibly in terms of ordinary or philosophical concepts, perhaps partially supplemented by mathematical concepts, which may be unconscious. It cannot be assigned existence or reality as independent of thought, somebody's thought.

In view of Gödel's incompleteness theorems, mathematics, at least if it is rich enough to contain arithmetic, cannot completely represent (and thus specify) itself: it cannot mathematically formalize all of its concepts, propositions, or structures and ultimately itself so as to guarantee its consistency. But it does not necessarily follow that the corresponding unspecifiable reality actually exists. One can make this assumption, as Gödel ultimately did on Platonist lines, claiming that there is, at least for now, no human means, mathematical or other, to specify this reality. But this assumption is not a consequence of Gödel's incompleteness theorems, which only imply that it is impossible to prove that all possible specifications, within any such system, are consistent. (As noted, Gödel's theorems do allow that a given system could be proven to be inconsistent.) What may be inconceivable is *why* this is the case and what is the nature of the reality responsible for this situation. This is, however, not a mathematical or even meta-mathematical question, any more than the question why our interaction with nature by means of quantum physics enables us to make correct probabilistic predictions. These questions concern the neurological nature of our thought, although they may not ultimately be answerable by neuroscience either. That is, the ultimate reasons why we think and for the way in which we think may also be beyond the reach of our thought, the alogon within a logos of neuroscience, which, again, need not mean that we cannot advance neuroscience under this condition.

One could speak in considering such as yet unspecified mathematical objects or concepts in terms of a hypothetical *potentiality*, defined by the assumption that a

mathematical object or concept of a certain type could or should exist. Such potentialities are, moreover, only partially, probabilistically, determined by what is sometimes called plausible reasoning, very important in mathematical thinking (Polya 1990). There are different and possibly incompatible way in which this potentially may be become reality. Consider the equation $X^2 + 1 = 0$ and complex numbers. While this equation (which may be assumed to exist in our thought) had no real-number solution, one could have and some had envisioned that it should have a solution and that a mathematical entity or a multiple of such entities, a new type of number, should exist. This hypothesis came to be realized insofar as complex numbers eventually became a mathematical reality. In the present view, however, they were not a mathematical reality before they were correspondingly specified in somebody's thought, in somebody's unconscious, by the time of Gauss, a crucial figure in giving complex numbers a mathematical reality – each time one thinks of them, consciously or unconsciously, but not otherwise.

In sum, in the present view, in mathematics, all reality is constructed, and this construction may, ontologically, involve multiple "mathematics." This multiplicity is also a consequence of Gödel's undecidability, as exemplified by Cantor's continuum hypothesis, mentioned above. This hypothesis was crucial not only for the question of continuity but also for the question of Cantor's hierarchical order of infinities (the infinity of which was one of his discoveries) and thus for the whole edifice of Cantor's set theory. The hypothesis was proven undecidable by Cohen. It follows, however, that one can extend classical arithmetic in two ways by considering Cantor's hypothesis as either true or false, that is, by assuming either that there is no such intermediate infinity or that there is. This allows one, by decisions of thought, to extend arithmetic into mutually incompatible systems, ultimately infinitely many such systems, because each on them will contain at least one undecidable proposition. I am not claiming that Gödel's incompleteness theorems form a necessary condition of this kind of multiplicity of possible mathematics, given, for example, that the existence of Cantorian and non-Cantorian set theory, or the existence of Euclidean and the various non-Euclidean geometries established earlier, does not depend on these theorems. Gödel's theorems, however, have given an inevitability of this situation. (I am grateful to an anonymous reader of this chapter for suggesting this qualification.) It is in principle possible to assume that all such possible constructions form a single, if multiply branching, potentiality, ultimately realizable in principle. I shall not assess this view except by noting that even if one adopted it, one would still only allow for a vast constructible mathematical potentiality rather than independent mathematical reality. Would this view be *in practice* equivalent to mathematical Platonism? While it may be in practice, the difference in principle remains important, both in general and because that it would be impossible to assume that, being infinite, this potentiality could ever be realized. In practice, mathematics creates new mathematical realities and, with them, new mathematical potentialities all the time, quite apart from any undecidable propositions.

This process will only end when mathematics is no longer with us, and 1 day it might not be, in contrast to physical reality, which, in either realist or RWR view, is assumed to exist apart from us, to have existed before we existed, and to continue to

exist when we will no longer exist. For now, however, as long as we exist, we can pursue our projects (logoi) of relating to this physical reality, either by continuing to assume it to be beyond construction (the alogon) or possibly by attempting to construct it as representable, by means of constructed mathematical realities that we can objectively share, rather than as mathematical objects existing independently of us.

5 Summary/Conclusion

This chapter introduced the concept of radical Pythagorean mathematics and considered its role in mathematical modernism, a trend that emerged around 1900, and has played a key role in the subsequent history of mathematics and its use in physics extending to our own time. As its name suggests, however, the history of mathematical thinking that this concept reflect is much longer and extends all the way back to ancient Greek mathematics, specifically to, arguably, the greatest discovery of the Pythagoreans, that of the incommensurability of the side and the diagonal of the square. This discovery established the complex relationships between geometry and arithmetic, and correlatively, the possibility of a new type of logos, a logos containing the alogon within it – a logical thought containing the unthinkable within it. I termed the mathematical thinking defined by these two features "Pythagorean mathematics." I have then argued that, as part of mathematical modernism, there emerged a new attitude toward the unthinkable in thought, an attitude that accepts this situation as a positive, enabling condition of thinking and knowledge. Ancient Greek mathematics was, at most, tolerant of this attitude, ultimately preferring what I termed Platonist mathematical thinking, defined by the belief in a logos without the alogon within it. I termed the mathematical thinking defined by the new attitude, which still keeps the irreducible relationship between geometry and algebra (which subsumes arithmetic within it), radical Pythagorean mathematics.

I have argued that the Pythagorean tension between geometry and algebra and yet their mutual dependence on and often symbiotic relationships with each other have never left mathematics and remain part of modernist mathematics and thus present-day mathematics. This is a good thing because they enrich and help to invent new forms of each other, sometimes to the point where one could no longer unconditionally distinguish geometry and algebra, and both topology and analysis may become part of mathematical architectures that thus emerge. That which underlies both and keeps them in this interplay – drifting them apart, bringing them close, intermixing them – may be beyond either, or beyond our thought altogether, thus forming the alogon within the logos of mathematics, even though we can still relate to this unthinkable by means of algebra or geometry, or their complex interplay. This possibility opens the way to radical Pythagorean mathematical thinking, which, against Platonism, affirms the unthinkable as a friend rather than an enemy of thought, because it does not preclude, but, on the contrary, helps the development of new concepts and theories. It only changes their nature, and in the first place the nature of thinking itself by making the unthinkable an unavoidable part of thought.

Thought remains our only measure of the Universe, even if the Universe may, as the Pythagoreans might have sensed, be beyond thought. The thought of this "beyond thought" is still only a thought. But it is also a testimony to thought's capacity to think beyond itself, without which, the Pythagoreans discovered, thought could not be the true measure of the Universe.

Abstract

This chapter constitutes an attempt to present a modern version of what Platonism in mathematics really entails. Thus one can view it as an attempt to get a closer approximation to Platonic Platonism and not get stuck in Plato's Platonism, which admittedly has great historical value, but when it comes to its specific details only such. In particular, the presentation takes exception to the post-Plato development of Plato's Platonism, the so-called Neo-platonism, which is an exalted version of Plato's thought but shorn off its irony. In particular, it constitutes a literal reading of Plato's metaphor positing a separate abode for forms and interpreting the immortality of the "soul" in personal terms. Those religious ideas are but a distraction irrelevant to the issue of mathematical Platonism, but unfortunately providing easy fodder for contemporary attacks and dismissals of it.

Physics is of course a human invention, but not a frivolous one, but created in response to a physical reality "out there." Mathematics as practiced is also a human activity on par with physics, and the content of mathematical Platonism is that it is also created in response to a "reality" which is "out there." While notions of beauty and virtue are ultimately a matter of social convention, knowledge is not, and just as there exists physical knowledge, we can also talk about mathematical knowledge not only as just being tautological. The latter view becomes seductive if you try to anchor mathematics in Popper's World One through

formalism, when it naturally resides in World Three of Popper, whose discovery incidentally Popper attributes to Plato. While beauty in mathematics is on par with beauty in the arts, it is part of a humanistic aspect of mathematics, not its Platonic. To exclusively place mathematics in the humanistic fold invites the abuses of post-modernism, whose classical antecedents are to be found in the teachings of the sophists, tellingly the mortal enemies of Plato.

1 Introduction

Platonism as a philosophical theory is well-known, and most of us probably came across his famous simile already as children. The image of people in the cave is a metaphor, and as all metaphors it is intended to stimulate thought not to kill it, which invariably becomes the case once you take them literally. Metaphors taken literally are indeed just silly, and for that reason Platonism has acquired a reputation of being unsophisticated, indeed philosophically naive, and long since outgrown, and its last worshipers to be found among primitive tribes made up of mathematicians. The analogy with Cartesian dualism naturally comes to your mind. Most of us in our daily lives (including philosophers) make a distinction between the world of the spirit, that is, our consciousness (or "soul"), on the one hand, and the world of matter, on the other. Likewise the working mathematician takes it for granted that the concepts he struggles with are indeed "real," real in the sense of existing outside himself and beyond the reach and domination of his will. It is for this reason, Yuri Manin speaks about Platonism as psychologically inescapable and intellectually indefensible. But is the issue of Platonism really on the same level as Cartesian Dualism? It is my intention to argue that it is not. Now such an argument can never be as convincing as a mathematical proof (and of course there is a great irony here which should not escape most readers), how can you prove that there is a Platonic world, and more to the point what is really meant by that? Traditional deduction in mathematics, as initiated by the Greek, is based on unproven statements as well as means of reasoning that obviously cannot be rationally supported. Contemplating the deductive procedure, we find ourselves in a metaphysical mode in which we cannot escape resorting to faith. As I understand it, the Greek did not strive for absolute certainty, the axiomatic method had as its purpose not to achieve absolute knowledge, for that the Greeks were too sophisticated, but to achieve transparency. A proof can be criticized, which is not the same thing as rejection, but being

amenable to modification and ultimately to improvement. Incidentally this constitutes the core of democracy, but admittedly most people would balk at the suggestion that the best education in democracy for young people would be to study Geometry in the time-honored tradition of Euclid. Yet what most people who acquire something positive from a mathematical education "take home" with them is an appreciation of the clarity and solidity of mathematical reasoning and the concomitant intellectual honesty and ultimate consensus that characterize it, even if they do not necessarily have any mathematical interest nor talent themselves.

I claim that philosophy is the poetry of science. Many people, especially philosophers, do not take kindly to such a suggestion, but see it as a disparagement, indicating groundless speculation, haziness, and obscurity in thought and ultimate ineffectiveness; but this is not my intention, the view of Bertrand Russell and Karl Popper was instead that philosophy is pre-science, and that it develops by amputation, once a field of philosophy has matured enough to possess clear concepts and allow itself systematic reasoning, it becomes part of science and is no longer philosophy. Much can be said for this view. The folly of the grand metaphysical theories, especially those of Hegel, in the eighteenth and beginning of the nineteenth century was that they treated lofty subjects in a systematic and technical way, in other words taking metaphors literally. The Old Hebrews understood this through their refusal to give their God a name; God was not meant to be part of any ordinary human discourse, to be treated as one entity among others. Thus in a metaphysical mode you cannot argue by straightforward arguments but need to resort to evocations, any other approach would just be a travesty. It is in this spirit I am forced to operate in the discussion to follow.

At the time of Plato you could speak about the True, the Good, and the Beautiful, as if they were more or less on the same level; nowadays in a more modern materialistic mode, most poignantly expressed by Darwin's Evolution by Natural Selection, which philosophers can only ignore at their peril, we make a distinction between ontology, that is, what really is, existing independently of man, and what is based merely on human whims and conventions, whose ramifications nevertheless, one should never forget, can be quite far-reaching and tangible. The question of mathematical Platonism is whether it has a real ontology, that is, existing independently of man; or whether it is to be thought of as a human invention on par with Art, Political and Legal constitutions, or Financial conventions, as suggested by Reuben Hersh. This latter view does not mean, that it thereby trivializes mathematics. After all even if you think of morality as merely a human invention, that does not imply that you do not feel strongly about moral crimes and transgressions, and that you do not have a strong intuitive feeling of what is right and wrong, and maybe even ready to die for it. In fact, as I understand it, the motivation for such an attitude is to demystify mathematics and thereby enrich it as a human endeavor on par with the highest achievements in Art. And also the fact that the value of money ultimately rests on a collective convention does not enable the individual to flaunt it. For the individual lack of money could be as real as lack of food. No serious philosopher of mathematics claims that mathematics is subject to the whims of the individual, as

little as an individual can on his own reinterpret the value of money, or moral concepts, although there has been no lack of trying.

Does mathematical objects exist in the same way as atoms? Atoms exist in space-time, but mathematical objects seem to have no tangible existence outside of the minds of humans. Now if you think of it deeper, the distinction is not as clear-cut as might at first be seen as being the case. The original distinction was between objects in the real world, and objects in an ideal world. A straight line, without thickness and irregularities cannot be manifested in the real messy world. But can an ideal line exist, a line as reasoned with in mathematics? There are many "lines" in the real world, and we think of them as approximations of the real thing, which we form an idea of through our minds. One common interpretation of this is that there exists an ideal line, of which all the lines we encounter are but distortions of. This gives the misleading idea that a Platonic object is the canonical object, which when applied to everyday objects such as chairs and tables becomes rather silly. Is there a Platonic chair, and if so how does it look like, can you sit on it? From a more Aristotelian point of view, the ideal object is not given, but constructed in our minds, thus it has no tangible physical existence. (Never mind that according to a material point of view going back at least to Hobbes, even thoughts have material manifestations as arrangements, be they elusive, of atoms in the brain. But the same "thought," whatever that means, can have different manifestations not only in different brains, but in the same brain at different times.) But our life is filled with concepts which we encounter in many very different ways, but which nevertheless are related to each other. To take a trivial example "crossing a street." The concept of crossing a street is of course very different from every instance of it, it would be silly indeed to single out a specific ideal street crossing as the canonical one of which all other street crossings are distorted images of. A dog cannot learn commands without having an abstract idea of what they refer to. For it to obey the command "do not cross the street" it need to understand what this entails in situations it has never encountered before. In what sense can we physically encode a concept? It does not really work to consider the agglomerate of all "crossing the street" situations, yet we cannot deny that the concept has some real existence with tangible consequences. One may of course cheat, as one does when trying to program a concept, by single out some easily identifiable features, but this does not capture the concept of a concept, although it could have its uses.

To bring the discussion down to a more concrete level, what about the integers? The classical way of approaching integers is via cardinalities. Cardinalities are abstractions which belong to conglomerations of objects, not to the objects themselves; in fact the latter does not even make sense. But if we have an empty universe do we have the notion of cardinalities at all, and hence of integers? Some Victorian philosophers such as J.S. Mill would probably argue not. But if we have a profusion of objects, different cardinalities can be manifested in many different ways and then it can be tempted to define numbers as equivalence classes of collections with respect to the same cardinality, but this is almost as impractical as defining a concept, such as "crossing a street" with all the manifestations of "crossing a street." (Frege tried a definition, obsessed as he was of getting an objective, Platonic definition of number

and to avoid the horror of basing it on psychology, according to him the least reliable and developed of all the sciences; but what he came up with was actually this anti-climactic definition.) One may of all the possible agglomerations choose a canonical sequence, such as $\emptyset$, $\{\emptyset\}$, $\{\emptyset, \{\emptyset\}\}$, $\{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$,... as suggested by von Neumann. This is a clever idea, or rather a clever codification of the integers to be implemented in the machine of logical thinking, and as such with definite applications; but it does not catch the Platonic concept of integers, which of course von Neumann never intended, although it may have been thought so by some; once again a case of the silliness of taking metaphors literally. What we are witnessing here is a twentieth-century attempt to bring integers into the machinery of logic; but as C.S. Peirce remarked, the notion of integers is more basic than logic itself. But here we have a clear-cut example of a mathematical object, more fundamental than the notion of a straight line in geometry. We can talk about ideal lines, as we encounter approximate lines in ordinary life, but we cannot talk about ideal numbers in the same way, because numbers with which we are familiar make already up an abstraction with which we are on very concrete terms with; it is not like that we have encountered defective numbers all the time, and decide that one set is the real ideal thing.

So to return to the initial question of the previous paragraph. What is more real and tangible, the mathematical concept of numbers or atoms? Atoms you can neither see nor touch but are mental constructions, and in fact originally they started out as pure items of speculations, be they the fruit of a powerful paradigm or thought, later on their identities and putative properties were progressively pinned down, acquiring in the process more and more reality, yet as late as the end of the nineteenth century, physicists turned philosophers such as E. Mach doubted their reality, seeing them as mere convenient fictions. (Einstein, who was much influenced by Mach, tried to rebut him by his technical description of Brownian motion, as being caused by random collisions between small organisms, such as bacteria, and molecules. Thus to a bacterium at least, atoms have a tangible existence! But of course they are presumably too small and primitive to experience this tangibility.) Numbers on the other hand have to our minds, and hence to us, a much more intimate existence, although in this regard we may fool ourselves. It is one thing to have a firm feel for small numbers, such as a million, but what about numbers we can define by recursion, by far outstripping anything so called astronomical? In fact thoughts, especially our own (as others we can only know through the medium of our own), so effervescent from a material point of view, are the only entities to which we have direct access. Logically this leads to the position of solipsism, or less dogmatically to idealism. In fact the fashionable attitude of instrumentalism, in which theories are but figments of the mind, is a species of idealism, as Popper pointed out, a stand more and more seductive as modern physics becomes more and more sophisticated. In order to make the discussion of mathematical Platonism meaningful we must posit the existence of an outside world beyond the realm of individual or human thoughts. In other words that thoughts mean something being occasioned by something "out there." We know the world through our senses, but our perception of it should not be confused by our conception of it. We are not instructed by the world, it comes with

no ready-made conceptions, but those we construct ourselves in response to our interaction with it. We form provisional hypothesis which we can test and modify on the basis of the perceptions we receive as a response. We may distinguish between two processes of familiarizing ourselves with our environment, namely the individual and the collective. In the first case it is a matter of making sense of sense perceptions, to be able to "see," "hear" and less cerebrally "smell," "touch," and "taste" and also to use your muscles and move around. Learning how to do so is a matter of automation, in which our conceptual understandings necessarily adhere to certain templates developed through evolution otherwise it would not be automatic and reliably effective. We can talk about evolution through natural selection, as a learning process for the species. In the collective process we try to delve deeper and trying to find an underlying explanatory coherence, in other words to seek the Platonic reality behind the confusing sensual manifestations. We are now speaking about science, in which we try to transcend our biological constraints and free ourselves from the templates with which we are born. This process is not automated and far from having any guarantees of success. As Popper teaches us, this trial-and-error approach carries over a spectrum from the most basic individual and biological to the most sophisticated scientific, so it is indeed impossible to draw a sharp line between the scientific and the individual.

Our intuitive sense of reality derives from the availability of many corroborating senses. The starry sky above us is only accessible by sight, while the terrestrial also allows us to move around in and touch.

> The Greeks were familiar with non-Euclidean geometry, namely the spherical one, but they had no need to think of it as a separate geometry, as the sphere is embeddable in ordinary Euclidean three-dimensional space. Spherical geometry was used for the celestial sphere, only accessible by sight, and Euclidean geometry for the space around us in which we can move. Obviously the celestial sphere is not as real as the terrestrial one (making a pun on the fact that the Earth is approximately spherical). The celestial sphere is an ideal one, and also perfect as a sphere, while the terrestrial one is a messy distortion. I would like to imagine that the Greeks would have made an even stronger distinction between the celestial and the sub-lunar world then they actually did. In fact that they would have believed that the objects in the sky were infinitely far away, and thus for ever beyond the reach of man, only mysteriously known by sight. However, there is of course no historical evidence for this being the case, although the idea no doubt occurred to some without leaving any documentary trace. However closer inspection of the sky do reveal, using elementary principles of Euclidean Geometry, that the Moon is actually at a finite distance from us, although substantial by purely terrestrial scales. From this we eventually derive the idea that the Moon is but a big stone in the sky, and that all the objects in the universe are actually at a finite distance and hence in principle accessible by means other than pure sight, making them much more "real." But what would have happened had we been born on a planet circling a star in the intergalactic void, we would have never been able to reach the lowest rung on the ladder which allows us to climb astronomical distances, the galaxies visible to us, would in fact be assumed to be infinitely far away without any means of falsification. (One may argue that a radiating body infinitely far way would not have infinite energy to send rays across such distances. But of course the physics infinitely far away could have been very different, or maybe the objects on the celestial sky may only have been part of a collective hallucination.)

Fiction differs from reality as there is only one channel, the written or the spoken word. There are many questions which can be asked about real people which cannot be asked about fictional ones. A real person has, for example, parents, who in their turn have parents, and you can ask all kinds of questions about them, but which do not make sense for fictional people (was Sherlock Holmes paternal grandfather bald when he died?) meaning they are neither true nor false. Historical people tend to be perceived as fictional, in fact many fictional figures live more vividly in the minds of people than most historical personages, to that we will return.

There is a material world out there, it is described and explained by subjects such as physics, chemistry, and biology. Those subjects are pursued by human beings and they exist in the minds of humans, but physics shall not be confused with the physical world. The pursuit of physics is made possible by interacting with the physical world, and this interaction can be very direct as being subjected by mechanical forces or very indirect through sophisticated experiments. (Never mind that our friend Mach considered forces "fictive.") The reality of our conception of it depends on that there are so many channels through which it can be tested, and the ways they cohere instill in us our convictions. Convictions are of course subjective feelings belonging to the realm of psychology, but after all we are human beings; but at the heart of Poppers claim for science stands that a falsification is real and objective. (In practice an experiment is complicated and its interpretation rests on further tested assumptions hence subjective convictions enter, yet this does not really invalidate the underlying principle.) Mathematics is different as the study of mathematics seems to coincide with mathematics itself. Thus if the study of mathematics is a human activity on the par with the pursuit of physics, mathematics itself should be a human activity and nothing more. In fact it is popular to think of mathematics as a language, following the adage of Galileo, that Nature is written in the language of mathematics. In fact much of the activity of theoretical physics consists in mathematical manipulation (which can be seen as a kind of experimentation) while that of experimental physics is more of an engineering activity. (In string theory the only resource is mathematics, experimental falsification being (so far) not feasible in fact inaccessible.) The implication of mathematics being a language is that it is ultimately free of solid content, that it only transmits contents, through organizing hard synthetic facts, not that it creates any. Mathematics by itself does not say anything about the world, just as language by itself is vacuous, it just conveys. This presumed vacuity can also be expressed in other ways, as we will see.

2 Axiomatics

The classical way of grounding mathematics to a solid reality is to present it axiomatically. This means treating mathematics as a game, rules are set up, and the game consists in following the rules. Originally the axioms and postulates were intended to match reality, and hence they were picked with great care. The axioms of Euclid were not chosen randomly but felt as being intuitively true. Once you had the axioms, which were meta-logical, you could use some simple logical principles to

churn out a wealth of propositions. Mathematics became applied logic. The rules of logic are ironclad and proceed with an inexorability akin to mechanical forces in the physical world. Mathematics literally kicks back at you, and you cannot flaunt its strictures. The experience of working with mathematics becomes a struggle against a resistant medium beyond your control. It is very different from writing fiction; in fiction you can impose your will, in mathematics you cannot. If the inequalities go the wrong way, you cannot just cheat and turn them around, as would be your privilege as an author of a tale. (But even authors of tales experience that they do not have complete freedom. Part of the restrictions are of course due to restraints imposed by a desire for realism and concomitant credibility, others more interesting is that authors report that characters take on a life of their own and "do" unexpected things that the author simply has to accept. Such experiences are no doubt genuine, yet it is difficult to conceive of them to have any objective character beyond that of psychological projections.) Now likening mathematics to a game is of course a metaphor not to be taken literally. In the typical game, such as chess and go, there is a competition between two opposing minds, and a mathematician would ask very different questions of the game that an actual player would. (This is why mathematical ability and playing say chess has not very much in common pace popular mythology.) Playing chess is a human activity, the objectivity lies in the fact that you can judge whether a game is played correctly or not, and the players come up against restraints given by the rules as well as the positions on the game. You cannot play chess against yourself (although a machine can). If we include games such as solitary, the simile gets closer to mathematics, yet even in solitary games you are not supposed to redo moves, while in mathematics and science in general, redoing moves constitute the essence of the "game" in the form of "trial and error." The relevant notion of a "game" is not the one of competition, where human involvement is crucial as well as there being a definite goal namely the notion of winning, but game as something well-defined and thus apart from "real life" implying frivolity and ultimate irrelevance. They do exist, and one can easily argue for their ontology, which basically consists in that rules may be arbitrary and chosen by humans, yet the consequences are unpredictable and beyond our control, thus having a tangible existence, regardless of relevance or interest, constituting a kind of self-sufficient mini-universe.

One aspect of the "game" nature of mathematics inherent in axiomatization is formalization, championed by David Hilbert. (Hilbert is often described as a formalist when it comes to mathematics. I think this is unfair; his formalism does not necessarily reflect his personal philosophical attitude toward mathematics, to him formalism was merely instrumental to serve some specific purposes, namely to prove once and for all the solidity, that is, the consistency of mathematics.) It means that the objects a mathematician deals with have no meaning in themselves only the ways they are being manipulated have meaning. That is, they are subject to specific rules in a game, and have no existence beyond that. Related to this is the notion that mathematics is about nothing at all and we have no notion of what we are speaking, as provocatively expressed by Russell; and furthermore that it is nothing but a collection of tautologies. Closely related to this is the idea that deduction does not

create any new knowledge (as opposed to induction), that all the conclusions are already to be seen in the premises (the axioms). The underlying assumption, or should we say vision, is that deduction can be done mechanically (in principle if not in fact) and one can imagine that all strings of permissible symbols are systematically generated and in particular all valid deductions. A variant of this, inspired by Kolomogorovs quantification of randomness, argues in the same vein, that the information content of any proposition in a logical system cannot exceed that of the axioms. The point is that any game creates a mini-universe which may refer to nothing at all, but by virtue of its existence, becomes something by itself of which you can ask all kinds of concrete and meaningful questions. Of a logical system we can ask the question of whether it is consistent, and the iconic inquiry of that type was supplied by Gödel, who noted that any game (formal system) can be encoded by the integers, thus any question about it can be coded as an arithmetical question, thus almost, but if not quite, embed a meta-question into one expressed in the system itself and thus draw the famous conclusions (provided of course that it it is powerful enough to encode the integers as well). A strict formalistic approach prohibits meta-mathematics (statements about mathematics) to become part of mathematics itself, just as the Hebrews were not allowed to give their God a name, and for that you pay a price, known as Gödel's theorem, and an application of Cantor's diagonal trick.

The deductive method is of course not confined to mathematics, but only in mathematics does it manifest its pure (Platonic?) form. The prime extramathematical application is of course the legal system. The legal system is an ambitious attempt to encode what is right and what is wrong. This is made much more complicated by the fact that not only the acts themselves enter, but the intentions behind them as well. It is interesting to note that the legal systems goes much further back in history than does mathematics and science proper which we should date to the pre-Socratic philosophers. The existence of legal codes and the institutions which go with them is inseparable from civilization itself, and as indicated above, it stands to reason that the axiomatic system was inspired by the legal system. There are of course clear analogies which make comparisons meaningful and thus highlight the crucial differences. While a set of axioms is usually quite simple, in modern societies the law consists of a huge number of individual regulations compiled to a large extent on ad hoc decisions. Furthermore the legitimacy of say the axioms of Euclid rests on a shared intuition (and when axioms are no longer based on intuition they form a mini-universe whose existence cannot be denied only tolerated), those of a legal code depends on external authority. Laws restrict the actions of individuals and societies in very tangible ways, mathematics restricts as well, but not so tangibly to most people. And more importantly laws are imposed by human will affecting that of others often contradicting them. Mathematical results have to be derived; laws have to be interpreted, because of the latter there has to be lawyers. This comes to the fore during a trial. The point of a trial is to come to a verdict, preferably within a short amount of time. Guilt or non-guilt is to be established (and sometimes a middle is not to be excluded) based on testimonies and through a deductive contest between a prosecutor and a defendant the outcome to be judged by some kind of jury, at times reduced to the judge. The aim of a trial is not to achieve absolute justice, and

although thought of as an inspiration it is not thought of as a realistic ambition; but to get a formal, that is, legal, justice. This reflects human fallibility. One may prefer the judgment of a single wise mind with a direct access to truth, but the advantage of a more formal procedure is that it is open for inspection. But due to the formality of the process it can be, and often is, distorted. The mission of the two main actors is not primarily to establish the truth but look out for the interests of their clients. As those interests are opposed this is seen as a check, both against omissions of relevant issues as well as specious reasoning. Cicero bragged that his final speeches were not supposed to survive a critical scrutiny the next day, but to dazzle the jury for the moment. The procedure is thought of as being democratic and consequently encouraged rhetorics where arguments are chosen to persuade and convince, not necessarily to lead to the truth. This is an attitude embraced by the Greek sophists, the mortal enemies of Platonism, and as such ironically more human. The correctness of a proof is from a Platonic sense independent of human opinion, in practice it is up to the judgment of experts. One may, as noted above, see mathematical proofs as Platonic entities beyond the ultimate judgment of mere human mathematicians. (Is Wiles proof correct? Most people could not tell, so a committee of experts is appointed to decide the matter. Admittedly they have no private axes to grind, and they are in principle indifferent to anything but the truth, yet they are human. So in the eyes of society there is no real difference between a proof deemed correct and a culprit proved guilty. We do feel that the putative guilt of someone is a matter on which there is a clear answer, after all a specific event once took place, but any human verdict is inevitably provisional and can be upset by the events of the future. In the same way, the fact that a proof may be deemed correct by a human committee does not mean that its ultimate correctness is just one of a social convention, as opposed to its actual acceptance by society.)

We have already referred repeatedly above to deductive reasoning being mechanical and unforgiving hence ultra-human. The mind of the mathematician may be very similar to the mind of a lawyer, and in fact many great mathematicians such as Fermat and Cayley were lawyers professionally (but their passion was of course mathematics). One may point to the same desire for precision in pursuit of clarity, and the same predilection for stringing long chains of deductive reasoning. While in mathematics such an approach is natural, its legal implementation appears in comparison to be pedantic not to say a parody, the reason for that being that the world of human affairs is very complex and confusing. Utmost precision needs a very precise language in which deduction is performed, and this allows the deductive process to be literally mechanized not just in principle.

Logical reasoning has much in common with machines. To put together a machine you have to have a clear idea of your intentions, and the way of trying to implement them are subject to the nonnegotiable restraints imposed by an unforgiving external reality. Some of those restraints can be formulated but most of them are discovered by trial and error. The guiding principle is one given by cause and effect, although the existence of such notions is up to doubt by skeptical philosophers. (Most notably by Hume. Cause and effect implies a “before” and an “after” and hence some notion of time. Mathematics, as opposed to human mathematical

practice as documented by the history of mathematics (which is not so much a history of mathematics as a history of mathematical practice), is in its Platonic sense, timeless. A mathematical theorem may be proven in many very different ways, without us asking which is the true cause of its veracity. Even in physics, so heavily mathematized, one may explain a phenomenon in different ways, such as reformulation of Newtonian mechanics using Hamiltonian, without us asking what is the real cause. Such fanciful explanations of the reflection of light due to Fermat, later to be developed into principles of least action initiated by P.L. Maupertuis, are fully legitimate as long as you do not pursue the antropomorphic interpretations they cry out for. Another case of metaphors taken too literally.) A machine exists first in the imagination of its inventor, but the process of translating a vision, often rather vague, into a physical object is not straightforward. External reality stimulates the imagination by putting up obstacles to overcome, the imagination is starved as it needs resistance to become properly stimulated. The translation involves a lot of trial and error, and thus involves a learning process, which will come in good stead for future projects. The finished result has grown out of a process of communication between the mind of the inventor and a resistant external reality. Once it is there as a material object it will exhibit a wealth of consequence which were never intended nor even predicted. Thus the object goes beyond the initial vision and becomes independent of its creator, and in the process blurring the distinction between invention and discovery which is often held up as crucial in any exploration of mathematical Platonism. A human invention is characterized by being the brain-child of a mind and thus brought forth by intention. Thus it is meaningful to ask "why"-questions; in fact it is essential. If you want to assemble something you can either follow a manual step-by-step, this is considered fool-proof, but often very frustrating; or better still you want to fathom the underlying thought which explains why the pieces look as they look and how they are meant to fit together. (It seems as if people in general prefer to get instructed by a Global Positioning System (GPS) rather than to figure things out by looking at a map. The same goes for mathematics, most people seem to prefer given explicit step-wise instructions on how to do it, rather than being given a "map" and figuring things out for themselves.) The inventions of tools goes way back into human prehistory and does not seem to be confined to humans alone, although admittedly no other species has pursued it to such lengths inventing machines to construct other machines and so on. The ambition also to implement mathematics into machines, to turn the spirit into flesh, has also a long story. One of the first examples being the abacus. (There is constant amazement on how the Romans could survive with their clumsy method of representing number, how could they compute with them at all? Those numbers served other purposes I suspect, purposes to which they are still used, when it came to calculation I am convinced they used mechanical apparati such as the abacus. The human capacity to subitize is very limited and does not go beyond four (just try to imagine in your mind a regular heptagon!) and is not superior to that of many mammals and birds such as rats and crows. Many human cognitive abilities do not measure up to that of many animals, thus the need of mental inventions, such as numbering systems and counting schemes.) More sophisticated machines were

thought up by Pascal, Leibniz, and Babbage, having the basic ideas but not the technology to support them, technology being in the nature of a collected human inventions. (Crucial to technological process is also non-material inventions; it is not enough to invent machines, they also have to be integrated in society's infrastructure, the interplay being rather subtle and complicated.) Traditionally the most sophisticated machines, if not necessarily the most useful, were clock-works, exhibiting the most intricate "deductive" chains of constructions, and one may cynically suspect why this made clock-work intellectually exciting. (Accurate clocks turned out in fact to be rather crucial for the determination of longitude with undeniable far-reaching practical applications in sea-faring. Apparently if you take apart one of Harrison's masterpieces, you see in the mechanism various dead ends corresponding to experiments, but which could not be "edited away" as in modern computer programs.)

Implementing visions into bona-fide physical machines are hard because unlike in logical reasoning it is hard if not impossible to break it down into simple discrete steps. In fact even the simplest steps can run into unforeseen difficulties. One says that some people are handy, while others are fumbling and hence cannot implement the simplest steps. The truth is that a skilled craftsman is not so much a question of a steady and nimble hand as mental understanding of what has to be done, but steadiness of hand and nimbleness of fingers do not hurt. (It is popular to contribute the growth of human intelligence on the one hand to manipulation of tools, and on the other social interaction. It is not true that there is an opposition between practical intelligence and theoretical, in particular not that a lack of the former is a sign of the latter. Newton was a master of both. And even in purely cerebral activities one may make a distinction. Gauss in his computations continually came up with clever tricks both out of necessity and pleasure, while Euler seems to have slugged through becoming blind in the process. One may speculate that as Euler had a tremendous memory, knowing large parts of literature by heart, this came naturally to him, while Gauss did not have such questionable gifts even if his computational cognitive capacities were impressive enough.) However, the programmable digital computer changed all that, enabling unpractical people, who had no talent nor desire to acquire so-called tacit knowledge, to construct machines through clear and simple step-wise processes, thus enabling straightforward implementation of logic. Now every program may be seen as a machine, be it virtual; as a logical system it can be seen as successful (consistent) if it runs, and useful and interesting if it eventually comes to an intended goal. (Getting to the goal, however, can take a long and unpredictable time, the so-called halting problem whose intrinsic undecidability is closely akin to Gödels incompleteness theorem and makes nonsense of many theoretical criteria such as Kolmogorov complexity.) A program also starts as a vision, and its implementation is also a matter of trial and error as anyone who seriously has tried to do programming has programming has inevitably found out. Although one may conceive a mathematical proof as a program, in practice programming has much more in common with constructing physical machines than the kind of activity which mathematics involves. (In mathematics you often get stuck, while in programming you can have a dialog with a machine in a much more palpable sense.) A program (and its execution) can be codified in a long string of "0s" and "1s," but such a string

written down on a piece of paper is inert and harmless, but once implemented in a physical machine (the hardware, the details of which tend to be completely unknown to programmers) which furthermore is integrated in the infrastructure of Society can cause unpredictable havoc. The perceived dangers of evolving AI lies in fact in this integration and in any ambition to be able to contain it, we have our best chances. However, the idea of a chain reaction of evolving intelligence is based on the ability of a program (a seed) to produce even better programs. Or in more abstract terms, to create an intelligence superior to human in the sense of being able to do all what humans can do, including creating an intelligence superior to its own, and so on. We note here how the abstract notion of intelligence which AI people seem to take for granted is given a Platonic existence without any protests. The crucial assumption that a transhuman intelligence can create an intelligence superior to its own reminds you of the ontological proof of God's existence due to Anselm. This is no coincidence as much of ultra-logical thinking is in the spirit of medieval scholasticism.

However, the general technological development seems to feed on itself and its course, and it and its impact on society is unpredictable, as any invention carries with it unintended consequences. It is far from certain that it will have a beneficial effect on humanity, as far as the latter has any objective meaning. Also on a more fundamental level there has been a blind development with a far more important impact. Ever since Big Bang matter, as we know it, has been created, more and more chemical elements have emerged as a result of nuclear processes in stars and their sometimes dramatic finales. Furthermore more and more complicated chemical compounds have arisen, in particular those that would eventually define life, at least on Earth, putting on stage a biological evolution of DNA sequences. The point is that this evolution has not been designed, and hence it is pointless to ask "why"-questions as Aristotle was fond of. Thus one may present as a criteria of the natural as opposed to the artificial, the absence of conscious design, in particular things arise blindly devoid of any aforethought. But Aristotelian final causes (so-called teleological) die hard, and there is a general feeling that evolution inexorably tends to higher and higher complexity (as in the perceived explosion of AI (which incidentally is supposed to evolve naturally, and thus should not be termed artificial)), although this is in contradiction with the physicists dogma of the inevitable rise of entropy.

There has been attempts to axiomatize nature, in other words to lay down true and complete natural laws. Once this is done, the pursuit of science can ostensibly become independent of empiricism and done, so to speak, cerebrally and formally. The first attempt to do so was Euclid axiomatization of physical space. (I am grateful to Davis and Hersh, who pointed that out in one of their books.) The very fact that Euclid is concerned with an external reality explains the excitement one as a schoolboy encounters because it gives you a feeling of immense power over that spatial reality by incorporating it all in your mind. You would not have felt the same excitement if you had been presented with the "axioms" of groups and asked to play along. Much of the ancient Greek legacy has been lost and it is possible that it contained extensions of Euclid who also wrote on Optics presumably in the same spirit. Archimedes also pursued physics in a mathematical sense, be it with physical

intuition he also applied to purely mathematical problems. (But such physical demonstrations did not qualify as rigorous proofs in his mind, only as suggestions of what could be true.) Naively at least it would not have been so difficult to formally axiomatize, and Newton tried to write Principia in the style of Euclid. In fact Classical Mechanics became for all intents and purposes a mathematical venture yet not totally separated from empirical considerations. The mechanical world can be seen as a real manifestation of a putative axiomatic system; as it has a real presence one concludes that it is consistent (In the parlance of logicians, it has a model). Also it means that there are no "hidden elephants," striking phenomena meets the eye, so to speak, while in a purely formal axiomatic system there may be striking theorems that have not yet been discovered and the ignorance of which prevents you from viewing its universe properly. The dynamical world is thereby richer than the merely geometrical one. The visual reality that meets us is that of changing perspectives, which could have been worked out by the Greeks, but if so there are no surviving documentations of it, it was of no concern to Euclid. (All the mathematics is there of course, but maybe there was no need for it, after all the theorems in Euclid are concerned with "Die Dinge an sich" not their ephemeral appearances to the human eye. It also illustrates the principle of selection which comes into play in the human pursuit of mathematics.) The mechanical world presents us with a wealth of phenomena that demands our attention and explanation, so even if you pursue it purely mathematically, say as an Euler you are aware of the physical reality around you, both as a corroboration and as an inspiration. (Even if Newton pursued physics mathematically, he also had a hands-on approach I doubt Euler had. His empirical investigations into the nature of light still provide an example to follow when it comes to doing science with its mixture of theoretical hypotheses and empirical observation.) While classical mechanics can be axiomatized the reasoning about it tends not be as formal as the mathematical which more closely follow the ideal set up by logic. This divergence between the mathematician and the physicist has become more and more pronounced. Some people (The British mathematician Brian Davies, for example) claim that this divergence is an argument against mathematical Platonism; I would argue to the contrary, it merely shows a divergence of mathematical practice, not mathematics itself. To axiomatize science means first to find all the natural laws and to formulate them in such a way that they can be manipulated by formal logical steps. Both of those conditions, especially the first, seem doubtful ever to be accomplished. Natural laws are for one thing provisional as Popper emphasizes, or as Hertz remarked, everything you learn from experience can be corrected by it. In fact from this point of view, mathematics is not, according to Popper, a proper science, as their conclusions are beyond doubt; in other words deduction versus induction. (As the British philosopher of history R.G. Collingwood put it: Deduction compels, induction allows.) One may argue, as did Mach, that scientific theories are not part of reality but of human imagination. (In the terminology of Popper, not part of World Two but solely of World Three.) And instead of trying to encapture reality into axiomatic systems, once and for all, one speaks about (mathematical) models, where rather than of having reality trying to approximate an ideal world, tentative approximations to reality are proposed subject to unending modifications prompted by empirical encounters. As an example we have in quantum

mechanics particle models and wave models both useful, but which one is true? This is a meaningless question, because we do not know "Das Ding an sich" and we have only more or less useful conceptions serving in different circumstances. Physics is a very mathematical science, and hence it is, as indicated above, somewhat misleading to speak of physics as applied mathematics, the physicists develop their own mathematics so to speak, while in other fields, say as economics mathematics is supplied more or less wholesale by the mathematicians. (One may argue that Game theory as introduced by von Neumann and Morgenstern is indigenous economics mathematics; true its most relevant applications are in economics, but it is a piece of pure mathematics conceived by a mathematician. It is also noteworthy that one may speak about a physical intuition powerful enough to solve problems in pure mathematics, but not of an economics intuition to perform the same feat.)

3 Imagination Gone Astray Seduced by Formalism

Even in logic there is an empirical element, as suggested above, in mathematical exploration you may encounter hitherto unknown principles of reasoning which makes it hard to completely encode a deductive process. Such principles of reasoning, however persuasive, may lead you astray, because after all principles of reason may be part of human psychology rather than of an objective world. In fact the fancier flights of logical reason may land you in a Carrollean Wonderland. A strict logical and axiomatic approach to mathematics runs the risk of becoming a travesty of mathematics. The effort to ground mathematics in Poppers World Two should be likened to represent pictures pixel by pixel. It has its undeniable uses, but a pixel representation does capture the essence of mathematics as little as it does of a picture. (Given the same pixels, it may very well induce different perceptions among different people; a fortuitous face, for example, could become obviously apparent to some but remain hidden permanently to others.) Convictions in mathematics are not objective; in particular they are not induced by long chains of deductions. What makes a mathematical statement believable in a deeper sense is how it fits with everything else in mathematics. As noted initially, our sense of reality derives from a multitude of channels which all cohere. The mathematics which comes out of logic and the language of set theory stands somewhat apart from mainstream mathematics and does not really engage with anything else. I am thinking of Cantors hierarchy of cardinalities which does have something shadowy to it. For a working mathematician there is the countable infinity and then the uncountable, not much more is necessary to consider. (Dieudonné in his textbook *Foundations of Modern Analysis* says that apart from the negative result that the reals are not countable nothing else is needed. The uncountability of the reals is of course crucial, without it measure theory with countable additivity would not be possible.) One could argue that uncountability is a metaphysical concept (and should not be pursued further. Remember do not give God a name!).

> The crucial idea is the notion of a subset, which we intuitively think of as going through all the members of a set one by one and deciding at each instance whether the element should be

included or not. This is an argument done in your imagination and seems innocent enough and when it only concerns a finite subset, especially of a finite super-set, it appears almost trivial. But finite numbers can be very big indeed, in fact a number defined through your favorite recursion could be mindboggling indeed and induce a sense of vertigo far more powerful than infinity itself, which is but a negative concept. (In some sense, except the strictly logical, we can embed the Cantorian infinities in the finite ones!) Now a subset defined by an infinite number of independent choices cannot be expressed in any finite way, those which can, thus based on some rule, will obviously only be countable, but all subsets form an uncountable set, by the Cantorian diagonal trick. (The Russell paradox is widely known. but of course it is explicit in Cantor's proof that the power set has higher cardinality than the set itself. So once you have a set that can generate its own power-set you have opened the lid to Pandora's box, the underlying idea behind the intelligence explosion.) Then you get the apparent paradox that you can model an uncountable set in a countable, due to Skolem. Seen from above, i.e. with the meta perspective, its countability can be detected but not from inside, as the sought for 1-1 correspondence does not qualify as a subset with a finite rule. This is highly unsatisfactory from an ontological point of view, as we have the notion of all subsets, not just the ones given by rules, which seem to us to exhibit a mere epistemological short-coming. But is one thing to imagine the subsets of a countable infinite set and one of an uncountable one, if we try, our imagination cannot go beyond that of picking one member at a time. Of course we can define subsets of the reals easily by rules, but it is hard to conceive of any other way, in particular the totality of all. This goes of course back to the Ancient Greeks and Zeno's paradox. We have no problems in our imagination to pass along a continuum and in a sense passing through every point, but in the classical paradox, we define a countable infinite subset at each specified point we cannot but stop to pause and become aware and thus the process seems never to end. In a similar vein imaginative processes such as the axiom of choice enter, hard to imagine, but maybe even harder not to imagine. (One should be careful dismissing things as being beyond the imagination. We can easily imagine two or three balls in front of us but not a thousand, although we could easily (if tediously) draw a thousand balls on a piece of paper. So in what sense do we imagine or not imagine? Mathematics is a way of greatly extending our powers of imagination beyond the directly imaginable. Even in mainstream mathematics one encounters "questionable" constructions such as the Absolute Galoisgroup of the rationals, for which we have great difficulties finding explicit elements apart from complex conjugation. But here we have a concept which ties in with others and hence allows alternate approaches.) Thus we are forced to make more or less artificial constraints as to what should count as a subset which seems to be on the same level as human legislation. In fact the Zermelo-Fraenkel system of axioms, ostensible the axiomatic basis of all of mathematics but which most mathematicians could not care less about, seems to be a collection of traffic rules to prevent undesirable pursuits of inquiry. Furthermore the inability to settle the Continuum hypothesis goes against our naive sense of the palpability of the real line. Gödel's idea is that we have not yet found the right axioms for set theory, when we find them we will recognize them. This is a Platonic statement if any, and ties in with Plato's idea that knowledge which is revealed to us is just a matter of remembering things we have forgotten, an experience which well describes the sensation we have of suddenly understanding something pointed out to us as if we have known it all along. Also recognizing things we have forgotten is a common human experience. (Admirably reported on in St-Augustine's confessions)

The meta-mathematical ideas which Cantor had introduced caused strong resistance that the logic and imaginative feats required seemed questionable and self-referential. It caused a crisis in mathematics, or rather the philosophy of mathematics; for mainstream mathematicians they did not really matter and they went on doing business as usual, pragmatism taking precedence over purity of thought.

Intuitionism which was advocated as a remedy against embarrassing paradoxes was never taken seriously by mathematicians in general but seen as a pedantic curiosity. Hilbert's attitude was one of tolerance and the need for freedom, if Cantorian arguments would turn out to be useful in getting results why should we not embrace them? In the end we would be vindicated according to Hilbert, hence manifesting a Platonic view. Time has shown that many classical existence proofs in analysis could be given constructive proofs after all. Maybe intuitionism is a matter of mathematical epistemology rather than ontology, just as the use of non-standard analysis.

4 Faith in External Reality, Including Mathematics

We do believe in a real world out there, something that lies beyond our imagination, even if our imagination of it is the only thing we can directly experience. The reason being, as having been noted repeatedly above, that all those perceptions fit together so well. The same is the thing with mathematics. It provides a web in which everything indeed fits so well together and we never cease to wonder at how the most disparate parts of mathematics connect to each other. As a feat of collective imagination it is unsurpassed, and as the imagination can only be stimulated by external constraints, there must be something out there that corresponds to it, just as an outside reality must correspond to the coherent web of perceptions we have. There is a remarkable consensus when it comes to mathematics which has no real counterpart in other human activities, including science. Of course there will be great differences in opinion when it comes to the importance of various mathematical results and disciplines, as well as the worth and standing of fellow mathematicians, whom should be prized or not, but when it comes to the core, what persuades one persuades the other, and if there is no persuasion one way or another it is due to lack of effort and motivation. To be told in mathematics that your argument is wrong is in principle not taken personally but accepted for what it is, a fact against which it is pointless to oppose better to accept and become instructed. The error is there, not created by the opponent, but in fact existing independent of him, your "opponent" is only a messenger. There is a huge difference between reasoning in mathematics and interpreting a law; the former is inexorable while the latter a kind of negotiation with extra-legal agendas. A sly lawyer looks for loopholes due to accidental deficiencies in the law to take advantage of. What would be the mathematical equivalence of a loophole? In artistic endeavors there is inevitable subjectivity, be it at times collectively shared. Art does not penetrate deeper than the "soul" of man, although admittedly this can be deep enough. There are of course strong artistic elements in mathematics, seeing its manifestation as a feat of imagination, but this imagination does not spring entirely from man, but from an external encounter. (There is no real contradiction to view the pursuit of science in artistic terms, and thus see it as a humanistic project. As has been noted above, theories are the fruits of imagination and involve the inventions of concepts, be it in physics as well as in mathematics. Those concepts, such as holomorphic functions, K-3 surfaces, and groups, are of course human inventions, although some concepts seem more human and ad hoc

than others, but they are subjected to constraints beyond our control, and involve unintended consequences. To define the notion of a holomoŕphic function say, does not mean that we thereby know everything about it. A classical artist concerned with the problem of mimesis becomes involved with an interaction between the tricks he invents in order to transfer his vision into a resistant medium and an observable reality. Thereby he is a scientist, as artists such as Dürer and da Vinci once saw themselves as. One only needs to be reminded of the laws of perspectives, which is mathematics. The singularity with mathematics is that its reality is "invisible" and thus the metaphor should not be carried too far.) This is ultimately not a logical argument, how could such be supplied, but a protestation of faith on par with our faith in an external reality, a philosophical stand of realism, without which science would be impossible. The further we probe, the difference between mathematics and science seems to blur.

Mathematical Practices Can Be Metaphysically Laden

Abstract

In this chapter I explore the reciprocal relationship between the metaphysical views mathematicians hold and their mathematical activity. I focus on the set-theoretic pluralism debate, in which set theorists disagree about the implications of their formal mathematical work. As a first case study, I discuss how Woodin's monist argument for an Ultimate-L feeds on and is fed by mathematical results and metaphysical beliefs. In a second case study, I present Hamkins' pluralist proposal and the mathematical research projects it endows with relevance. These case studies support three claims: (1) the metaphysical views of mathematicians can shape what counts as relevant research; (2) mathematical results can shape the metaphysical beliefs of mathematicians; (3) metaphysical thought and mathematical activity develop in tandem in mathematical practices. This makes metaphysical thought an integral part of mathematical practices.

Keywords

Set theory · Set-theoretic pluralism · Metaphysics · Ultimate-L · Mathematical practices · Set-theoretic multiverse

In this chapter, I argue that the metaphysical views mathematicians hold can shape what counts as relevant research in mathematical practices. I will furthermore show how these metaphysical views are in turn shaped by the results of formal mathematical research. This makes metaphysical thought an integral part of mathematical practices: mathematical practices are metaphysically laden.

To make my argument, I present two case studies from set-theoretic practice. Set theory is arguably more heavily shaped by the metaphysical views of its practitioners than other mathematical practices. In set-theoretic practice, it is particularly visible how metaphysical beliefs and mathematical activity shape each other. This makes set theory a suitable mathematical discipline to study for the aims of this chapter. It also limits my sample space. I only show that one mathematical practice is metaphysically laden, not that all of them are. Hence the "can" in my title. I will come back to this point in the conclusion of this chapter, where I will briefly suggest why it is reasonable to expect that some other mathematical practices are metaphysically laden as well.

Set theorist Hamkins (2012, p. 449) supports the claims of this chapter when he writes that "the mathematician's measure of a philosophical position may be the value of the mathematics to which it leads. Thus, the philosophical debate here may be a proxy for: where should set theory go? Which mathematical questions should it consider?" Hamkins then introduces the *modal logic of forcing* and *set-theoretic geology* as two mathematical research projects which are inspired by his proposed philosophy, the *multiverse view*. This is one direction of the reciprocal relationship between philosophical thought and formal mathematical research I explore in this chapter: Hamkins' metaphysical position, the multiverse view, gives relevance to these two set-theoretic research projects. As for the other direction, Hamkins argues for his multiverse view on the basis of the set theorists' experience with certain formal mathematical results. The claim of this chapter is that philosophical views and mathematical projects develop in tandem; neither is prior to the other. Benedikt Löwe (personal communication, 2016) reported that when he and Hamkins started to collaborate on the modal logic of forcing during a visit of Hamkins' to Bonn in the summer of 2004, their work was neither motivated by nor based on any philosophical considerations about the nature of the multiverse. I argue in this chapter that the metaphysical views mathematicians hold and their formal mathematical activity develop together and may inform each other along the way.

I base my argument on two case studies: the interpretations of the undecidability-situation in set theory by Woodin and Hamkins. The set theorists are currently having a debate about how certain set-theoretic results should be interpreted, the so-called *set-theoretic pluralism debate*. Roughly, Woodin argues for monism and Hamkins for pluralism. Both agree that mathematical objects exist in a vaguely lower-case p platonic sense (Hacking 2014), but they disagree on the nature of this existence; their disagreement is about metaphysics not ontology. Whether and how ontological or other philosophical differences are a part of mathematical practices is left for future research. In this chapter I argue that mathematical practices can be metaphysically laden in the sense described above.

In Sect. 1 I introduce the epistemic situation the set theorists are currently in. I focus on the issue of undecidability and set-theoretic monism as the orthodox view in set-theoretic practice.

In Sect. 2 I present and discuss Woodin's Ultimate-L argument. I introduce the Ultimate-L axioms, Woodin's arguments in support of these axioms, the mathematical program they drive, and highlight the reciprocal relationship between the mathematical results and metaphysical views in Woodin's arguments.

In Sect. 3 I present and discuss Hamkins' multiverse view. I explain his pluralist proposal, introduce the modal logic of forcing and the set-theoretic geology projects, and point to the interplay of Hamkins' metaphysical views and his formal mathematical research.

In Sect. 4 I give a short summary of the preceding sections to highlight salient points and briefly suggest why it is reasonable to expect that other mathematical practices are metaphysically laden as well.

1 The Set-Theoretic Pluralism Debate

Rouse (1996, p. 27) has pointed out that "what scientists share is not a background of beliefs but a situation that they may belong to and understand in partially different ways." In this section I argue that this is also true for set theory. My focus is on the situation as given by the mathematical results set theorists have obtained.

There are limits to the formal machinery of set theory, e.g. the independence results, with which set theorists routinely come into contact (see e.g. (Džamonja and Kant 2019; Rittberg 2016b) for accessible overviews). Individual set theorists interpret this situation in partially different ways: some seek to overcome the paucity of the formal machinery of set theory by proposing new axioms, others interpret the independence results as a sign of the limitations of our epistemic grasp on set-theoretic propositions, and others still understand the situation they are in as revealing metaphysical truths. In this subsection I elaborate on these points by presenting the situation the set theorists currently face in more detail.

The currently accepted system of axioms of set theory are the Zermelo-Fraenkel axioms with Choice, ZFC for short. There are set-theoretic propositions, such as the Continuum Hypothesis CH, which can neither be proved nor disproved from the ZFC axioms. That is, even if we accept the ZFC axioms as true we still do not know whether CH is true or false. This is the well-known *incompleteness* of ZFC, witnessed here by the *independence* of CH from the ZFC axioms. Set theorists also say that CH is *undecidable in* ZFC, which, for the purposes of this chapter, is just the same as saying the CH is *independent from* ZFC. Undecidability (and hence independence) are formal notions; set theorists can prove that CH (and many other propositions) are undecidable in ZFC.

The undecidability of a proposition is relative to the axiom system considered. A proposition may be undecidable relative to ZFC, but decidable in some extension of ZFC by an axiom A, ZFC + A for short. For example, if A is the axiom stating that every set is constructible in Gödel's sense, then ZFC + A proves CH. That is, given

ZFC + A, then the Continuum Hypothesis is true. Since it is common set-theoretic practice to accept ZFC, the question is whether A should be accepted (e.g. Jech 2006, p. 157). Indeed, accepting another axiom may imply that the Continuum Hypothesis is false instead. Which axiom(s) to add to ZFC is a deeply mathematical question and highly skilled and respected mathematicians engage with it in the debate that is the focus of this chapter (Baldwin 2018; Antos et al. 2015; Steel 2014; Väänänen 2014; Hamkins 2012; Magidor 2012; Woodin 2011c; Shelah 2003). But the question cannot be answered by the formal machinery of mathematics. Nothing could prove, in any ordinary mathematical sense of the word, that A should be accepted or rejected. What is needed is thus a convincing rational argument for (or against) A, and this argument cannot be a formal proof.

Gödel put to the debate the idea that for some undecidable propositions there can be no convincing rational argument for any extension of ZFC that would decide whether the proposition is true or false. He wrote:

> The consistency of proposition A (that every set is constructible) is also of interest in its own right, especially because it is very plausible that with A one is dealing with an absolutely undecidable proposition, on which set theory bifurcates into two different systems, similar to Euclidean and non-Euclidean geometry. (Gödel 1995, p. 155)

Gödel suggests in this quotation that there may be *absolutely undecidable* set-theoretic propositions, that is, propositions which are (a) undecidable in ZFC and (b) there can be no convincing rational argument for or against the proposition. As is well-known, he later turned against this view. For the later Gödel, there are no absolutely undecidable propositions (e.g., Gödel 1947).

Notice that, unlike undecidability, absolute undecidability cannot be formally proven. It is a conviction one might have about a proposition rather than a formal result.

The question whether there are absolutely undecidable propositions lies at the heart of the set-theoretic pluralism debate. Set theorists regularly deal with the limits of their currently accepted formal machinery. They face the situation that there are set-theoretic questions which they consider relevant, such as whether the CH is true or false, which are provably unanswerable from the widely agreed upon intellectual resources of their practice. With Rouse (1996), it is unsurprising that they interpret this situation in partially different ways. For some set theorists, the limits of the available formal machinery indicate that certain set-theoretic questions may not have a "true or false"-answer, they are absolutely undecidable. These are the pluralists. Other set theorists argue that the inability of the currently accepted methods to answer "true" or "false" to certain set-theoretic questions is a paucity of the methods, not a challenge to the idea that mathematical statements are either true or false. These are the monists. The later Gödel is a monist in this sense.

The *set-theoretic pluralism debate* is the debate about how set theory as a discipline should deal with the issues of undecidability, the limits of its formal

machinery, and the questions about which axioms should be elevated to the same status the ZFC axioms currently have. This debate is also known as the *foundational debate* (Maddy 2011, 1997). Noteworthy contributions to this debate by set theorists include (Baldwin 2018; Antos et al. 2015; Shelah 2014; Steel 2014; Väänänen 2014; Magidor 2012; Shelah 2003) and the works of Woodin and Hamkins I will introduce in the following two sections. This debate has been the focus of much of the contemporary philosophizing about set theory, including Barton (2019), Centrone et al. (2019), Tanswell (2018), Rittberg (2015), Kennedy (2014), Kennedy and Kossak (2011), Maddy (2011), Koellner (2006).

It will be helpful for the purposes of this chapter to distinguish two forms of set-theoretic pluralism. *Epistemic pluralists* hold that our epistemic capacities may be too limited to know the truth-value of some set-theoretic propositions. Those propositions which are beyond our epistemic grasp are absolutely undecidable. Von Neumann's was an early suggestion of a form of epistemic pluralism in set theory:

> Das abzählbar Unendliche als solches ist unanfechtbar . . . Aber seine Grenzen scheinen sehr verschwommen und ohne anschaulich-inhaltliche Bedeutung zu sein. (von Neumann 1925) (The denumerable infinite as such is beyond dispute. . . But its boundaries seem to be quite blurred and to lack intuitive, substantive meaning; translation from (van Heijenoort 1967).)

Metaphysical pluralists hold that there are multiple universes of sets and propositions are true only relative to the universe considered. Those propositions which are true in one universe but false in another are regarded as absolutely undecidable. Hamkins is a well-known metaphysical pluralist; I discuss his views in Sect. 3.

Accordingly, *epistemic monists* hold that our epistemic grasp is in principle unlimited. *Metaphysical monists* hold that there is only one universe of sets, which is often called the "true universe of sets." Woodin, whose position I discuss in the next section, favors forms of epistemic and metaphysical monism.

My focus in this chapter is on the metaphysical variants of the set-theoretic pluralism debate. I will from now on drop the specification "metaphysical," employing it only where the argument benefits from fine-grained specification.

At this point I have introduced the undecidability-situation contemporary set theorists are in and outlined some of the different proposals endorsed by set theorists to understand this situation. Crucially for what follows, there is an orthodox interpretation of the undecidability-situation in set theory. Maddy (1988, 1997, 2011) provides a successful career-length argument that the orthodox position is monism. Criticism of Maddy's work on this issue has focused on her claim that set theorists should still be monists today (Ternullo 2019; Rittberg 2016b; Antos et al. 2015; Friend 2014). That monism is the historically orthodox position in set theory is not under dispute.

Set theorists also present monism as the orthodoxy in their publications. This orthodoxy vibrates through, for example, Woodin's (2011c) label of a monist

position as "The Set Theorist's" response to a skeptic (see also next section); Väänänen's (2014, p. 180) remark that "the phrase 'multiple realities', as well as 'parallel universes', may sound immediately self-contradictory and ill defined. We try to make sense of it anyway"; Magidor's (2012, p. 3) interpretation of his claim that "the main motivation for set theory is still its foundational goal"; Steel's (2014, p. 154) view that we need a "stronger foundation for mathematics"; Hamkins' (2012, p. 416) claim that monism is "the commonly held philosophical position" in set theory (see Sect. 3).

The empirical question whether monism is the most commonly held position among set theorists I leave unanswered in this chapter. I note, however, that numerous young set theorists (PhD students and postdocs mostly) have told me in unstructured personal discussions that they do not endorse monism.

In what follows I refer to monism as the orthodoxy in the set-theoretic pluralism debate. By this I mean that monism is part of the cultural history of set theory and still shapes the practice today. Those who challenge the position need to argue against it while those who endorse it can and often do assume it without much ado. Indeed, monists tend to focus on the problem the undecidability results pose for monism and offer proposals to engage with or even overcome these problems. This will be visible in Woodin's argument for a monist resolution of the undecidability issue in the next section. Pluralists tend to stress new insights or evidence that challenges the monist orthodoxy. I discuss Hamkins' argument for pluralism as an example in Sect. 3.

It bears stressing here that I explicitly do not claim that monism is the most commonly held position among set theorists. In fact, I believe this claim to be false. This belief I base on various personal communications I had with set theorists over the years. A satisfying answer to the empirical question which view is most common among set theorists is still missing (but see Džamonja and Kant (2019) for preliminary empirical work).

The situation the set theorists currently share is, in the parts relevant for this chapter, shaped by mathematical results about undecidability and an orthodox philosophical view about what it is the discipline studies. This situation is interpreted differently by the contemporary set theorists. Woodin, whose argument I present in the next section, interprets the undecidability results as problems to be overcome and provides an argument how this could be achieved. Hamkins, whose position I present in Sect. 3, interprets the undecidability results as ingredients to a counterargument to the monist orthodoxy. Relevant for this chapter is that neither argues purely philosophically: both mathematicians rely on mathematical results as evidence for their philosophical positions. Furthermore, both mathematicians explore mathematical programs whose relevance is grounded in their philosophical views on the undecidability issue. The argument of this chapter is that there is a reciprocal relationship between the mathematical activity and the metaphysical thoughts these two set theorists put forward. To make this visible, I discuss first Woodin's and then Hamkins' projects in detail in the following sections.

2 Woodin's Ultimate-L Argument

W. Hugh Woodin is a highly respected member of the set-theoretic community. He was affiliated with the informal but very influential group of set theorists known as the Cabal, which was particularly active in the 1980s and 1990s in Berkeley, California. Woodin has produced numerous influential publications and is widely regarded as one of the leading set theorists of today; a certain type of large cardinal (see below) carries his name: Woodin cardinals. Around the year 2000 he developed an argument for the so-called star-axiom as a contribution to the developing set-theoretic pluralism debate. In the first decade of this millennium, he gave up this argument and now proposes an argument for an Ultimate-L. In the historically minded (Rittberg 2015), I present both arguments in detail. Here I focus exclusively on the Ultimate-L argument.

Relevant contributions to Woodin's Ultimate-L argument include Woodin (2010a, b, c, 2011a, b, c), Koellner and Woodin (2009, 2010), Koellner (2011).

Woodin is a monist. As mentioned in Sect. 1, this is the orthodox position in set theory and Woodin provides little argument for it in his writings. Instead, he argues indirectly by challenging two non-monist positions.

Woodin (2011c) challenges skeptic, a literary figure who views the universe of sets as "a complete fiction" (p. 449). That is, Woodin is more concerned with an ontological rather than a metaphysical question here. Skeptic's positions do not reflect those of any set theorist contributing to the set-theoretic pluralism debate. Woodin argues that skeptic cannot account for the consistency results his Ultimate-L project will produce. Woodin sees this as evidence for the existence of "the transfinite universe" (2011c, p. 470), the definitive article indicating that there is only one such universe. Skeptic does not reappear in Woodin's later writings.

Woodin (2011d) challenges what he calls the generic-multiverse conception of truth. According to Woodin, the undecidability of CH in ZFC is "often cited" (2011d, p. 13) as evidence that the CH has no answer. Woodin formalizes this idea (2011d, p. 17), the result of which is the generic-multiverse conception of truth. Woodin does not discuss what is lost in this formalization, nor whether his formalized version successfully tracks the philosophical positions put forth in the set-theoretic pluralism debate. Woodin summarizes his argument:

> The essence of the argument against the generic-multiverse position is that assuming the Ω Conjecture is true (and that there is a proper class of Woodin cardinals) then this position is simply a brand of formalism that denies the transfinite by a reducing truth about the universe of sets to truth about a simple fragment such as the integers or, in this case, the collection of all subsets of the least Woodin cardinal. (Woodin 2011d, p. 17)

For details on the Ω conjecture and the point about Woodin cardinals, see Rittberg (2015).

Foreshadowing the next section, I note that Hamkins appropriated the multiverse terminology from an earlier version of (Woodin 2011d). Hamkins also points out in (2012, p. 445), which appeared later than (Woodin 2011d), that his multiverse view is not the generic-multiverse view.

Monism is part of what drives Woodin's work on Ultimate-L. From his monist point of view, the undecidability situation in set theory is a problem. He sees set theory haunted by a "specter of undecidability" (Woodin 2010a, p. 17) and speaks of "The ZFC Dilemma: Many of the fundamental questions of Set Theory are formally unsolvable from the ZFC axioms" (Woodin 2011c, p. 449). As becomes clear from the surrounding text, Woodin intends "dilemma" in the quotation in its informal meaning as a difficult situation or problem, rather than as a choice between undesirable alternatives. His Ultimate-L argument is a proposed (and still developing) answer to this problem. That is, Woodin holds a philosophical view, monism, for which certain formal mathematical results are problematic. The aim to resolve these problems gives relevance to Woodin's work on Ultimate-L. His metaphysical views provide the relevance for his mathematical research project here.

To understand Woodin's proposal to tame (and possibly banish, see below) the specter of undecidability, it is important to have a grip on the interplay of undecidability and large cardinal axioms. The key point is that set theorists can order undecidability along the large cardinal hierarchy. I offer a brief exploration of this issue here.

Large cardinal axioms are strong axioms of infinity: they state that certain infinite sets exist whose existence cannot be proven from ZFC. Kanamori (2009, p. 472) lists 28 different types of large cardinal axioms, but since there is no clear-cut definition of what makes a set-existence statement a large cardinal axiom, this list is subject to interpretation as well as further developments in set theory. Note however that there is remarkably little discussion in day-to-day set-theoretic practice about whether a certain axiom counts as a large cardinal axiom or not. For a large cardinal axiom LCA, ZFC + LCA proves the consistency of ZFC, which is famously unprovable from ZFC alone (due to Gödel's incompleteness theorems) - I am assuming here and throughout that ZFC is consistent. The mathematical vernacular is that ZFC + LCA has a higher *consistency strength* than ZFC. Indeed, for any two large cardinal axioms A and B, it holds that the consistency strength of ZFC + A is at least as high as ZFC + B or vice versa. That is, the large cardinal axioms form a linear order along consistency-strength: the so-called *large cardinal hierarchy.* Notice how this formulation suppresses the distinction between a large cardinal, which is a set, and a large cardinal axiom, which states that a certain class of cardinals exists. This is common practice in set theory as it is generally clear from the context what is meant and I follow this convention in this chapter; I here order the large cardinals by consistency-strength. Another common ordering relies on the fact that large cardinal properties carry over. For example, every Woodin cardinal is also a measurable cardinal but not vice versa. In this sense Woodin cardinals are stronger than measurable cardinals. This ordering aligns with the ordering by consistency-strength in all but one case: real-valued measurable cardinals are neither stronger nor weaker than weakly compact cardinals in this ordering. This makes the property-ordering a nonlinear ordering. Real-valued measurable cardinals are stronger in consistency-strength than weakly compact cardinals. Because the large cardinal axioms have been identified in vastly different contexts and their initial formulations share no obvious connections, the fact that they can be linearly ordered along their

consistency strength is a remarkable emergence of regularity and a source of wonder and marvel among many experts; see (Kanamori 2009) for technical results and historical remarks.

The large cardinal axiom stating that a Reinhardt cardinal exists is inconsistent with ZFC. Reinhardt cardinals thus form an upper bound of the large cardinal hierarchy in the context of ZFC, even though Reinhardt cardinals and even stronger large cardinals have been meaningfully studied in the context of ZF, that is, ZFC without the axiom of choice, since no inconsistency of these theories is thus far known; for example, Cutolo (2019). For large cardinals weaker than Reinhardt cardinals, no such inconsistencies with ZFC are (yet?) known. "The investigation of [such] large cardinal hypotheses is indeed a mainstream of modern set theory" (Kanamori 2009, p. XI).

To order undecidability in ZFC, set theorists can calibrate the *degree of undecidability* of (some) set-theoretic propositions using the large cardinal hierarchy. This is sometimes referred to as *degree of unsolvability*, for example, Woodin (2011c). Say P is a set-theoretic proposition which is undecidable in ZFC. Set theorists can then search for the smallest large cardinal axiom LCA such that ZFC + LCA decides (i.e., proves or disproves) P; such searches have sometimes taken years of international research efforts and led to new developments along the way. For example, work on the axiom of projective determinacy took years and contributed to the development of Woodin cardinals. See Martin and Steel (1987) for helpful remarks. A satisfying history of the development of Woodin cardinals is still missing. The degree of undecidability of P is then LCA, which can then be compared to the degree of undecidability of other set-theoretic propositions. This way the large cardinal hierarchy can be used to order undecidability along the large cardinal hierarchy. However, not every set-theoretic proposition is decidable in some large cardinal extension of ZFC. For example, CH is undecidable in all known large cardinal extensions of ZFC.

I now return to Woodin's Ultimate-L argument. As we saw he seeks to tame the specter of undecidability. A prominent way to do so is *Gödel's program*:

> Decide mathematically interesting questions independent of ZFC in well-justified extensions of ZFC. (Steel 2014, p. 153)

Large cardinal extensions of ZFC can answer mathematically interesting questions which are undecidable in ZFC; e.g., they can determine whether projective sets are Lebesgue-measurable. The *inner model program* seeks justifications for such large cardinal extensions. As I will show momentarily, this program has certain limitations (versions of Scott's theorem). Woodin's argument for an Ultimate-L rests on a proposal to overcome these limitations.

The basic idea of the inner model program is to build "mathematically accessible" (i.e., L-like, see below) set-theoretic models in which large cardinal axioms hold.

The completeness theorem implies that ZFC is consistent if and only if there is a model of set theory. In a model of set theory, every set-theoretic proposition is either true or false, that is, undecidability is an issue for theories, not for the models of these

theories. Indeed, a proposition P is undecidable in ZFC if there are two ZFC models, one in which P is true and one in which P is false.

Set-theoretic models tend to be resistant to mathematical exploration. Set theorists have means to construct models in which certain targeted propositions hold; they can construct a model for non-CH, for example. However, it is generally not possible to discern whether some other proposition is true or false in the constructed model. This is different for Gödel's constructible universe L. Assuming the consistency of ZF, Gödel constructed the model L, which, unlike most other models, can be studied with relative ease. Today, the so-called *structure-theory* of L, that is, what is true and false in L, is well understood.

An important result for the inner model program is Scott's (1961) theorem. It states that there are no measurable cardinals in L. Measurable cardinals are in the middle of the large cardinal hierarchy and Scott's result implies that there are also no large cardinals stronger than measurable cardinals in L-here and throughout I employ this visual language to generate "a feel" for the strength of the LCA in question; I rely on Kanamori's (2009, p. 472) chart of large cardinals for my positional judgements. The inner model program seeks to construct models that (a) can accommodate such stronger large cardinals and (b) whose structure theory is similarly accessible to that of L, that is, are L-like.

The inner model program has successfully constructed L-like models for some large cardinal axioms. The general heuristic is to target a large cardinal axiom LCA and assume that ZFC + LCA is consistent. The completeness theorem then ensures that there is a model for ZFC + LCA, but it may not be L-like. The inner model program seeks to construct an L-like model for ZFC + LCA. If this can be done, then this is viewed by the proponents of Gödel's program as justification for the belief that ZFC + LCA is consistent. It may seem as if there is a circularity here: ZFC + LCA is assumed to be consistent in an argument for the consistency of ZFC + LCA. Proponents of the argument hold that the construction of the L-like model adds sufficient evidence to justify the conclusion.

In all these L-like models the inner model program produces, a version of Scott's theorem holds, that is, only the targeted large cardinal axiom LCA but no stronger axiom is part of the structure theory of the constructed model. This has led to a stepwise approach in which the set theorists produce such L-like models for stronger and stronger large cardinal axioms. The currently strongest results are the Mitchel-Steel extender models, which can accommodate Woodin cardinals (Mitchel and Steel 1994); Woodin cardinals are two thirds up in the large cardinal hierarchy.

Woodin shows that "and this is the surprise" (Woodin 2011c, p. 465), if the set theorists would succeed in building an inner model of the desired kind for a supercompact cardinal, then this model could accommodate essentially all large cardinals, even those that are stronger than supercompact cardinals. That is, in such a model, versions of Scott's theorem would not hold. This structure would be L-like, that is, its structure theory would be accessible to mathematical exploration, and it would accommodate essentially all large cardinal axioms. Woodin calls it an *Ultimate-L*.

Supercompact cardinals are about three quarters up in the large cardinal hierarchy. The inner model program has thus far not succeeded in constructing an inner model which could accommodate supercompact cardinals. Thus far no Ultimate-L has been constructed. However, Woodin has produced a family of axioms, each expressing the idea that the universe of sets, called V, is an Ultimate-L, expressed as V=Ult-L.

The V = Ult-L axioms are powerful. ZFC + V=Ult-L + LCAs, whereby V=Ult-L stands for one of the Ultimate-L axioms and LCAs stands for a schema expressing that large cardinals exist, decide all contemporarily known formal questions about sets:

> There is no known candidate for a sentence which is independent from [a version of V = Ult-L] and which is not a consequence of some large cardinal axiom. (Woodin 2011c, p. 470)

To note how strong this is, recall that some propositions, such as the Continuum Hypothesis CH, are undecidable even in large cardinal extensions. In a V=Ult-L model however, CH and all other known propositions like it become decided. In this sense, the V=Ult-L axioms tame the "specter of undecidability."

Two principal issues remain. First, set theorists have not yet succeeded in constructing an L-like model which can accommodate a supercompact cardinal (and it is at least theoretically possible that this cannot be done for reasons as of yet unknown). This point requires further mathematical investigation and I will say no more on it in this chapter. Second, there are multiple versions of the V=Ult-L axioms which contradict each other; for example, CH is true under one version of the axiom but false under another. These multiple versions of the V=Ult-L axioms are the focus of what follows.

Woodin and his close colleague Peter Koellner have proposed the *convergence argument* to choose between the different versions of the V=Ult-L axioms (Koellner 2013). They propose to analyze the structure theories of two models under each of the V=Ult-L axioms. One of these models has already received much attention from set theorists and is well understood; the other model has not yet received much attention. If the structure theories of these two models converge under the given version of V=Ult-L, then this counts as evidence in favor of this version of the axiom; if the structure theories diverge, then this counts as evidence against the axiom.

The first model is L($\mathbb{R}$), a model which is constructed just like Gödel's constructible universe L but instead of starting with the empty set, one starts with the set of all real numbers $\mathbb{R}$. There is some monism lurking in the imperative to start from "all real numbers." For the monist there is only one "true" set of all real numbers. The pluralist Hamkins disagrees. For him each set-theoretic universe comes with its own set of real numbers; see next section. L($\mathbb{R}$) "has figured prominently in the investigation of strong hypotheses" (Kanamori 2009, p. 142) and set theorists have an intimate understanding of it. For example, it has featured in the analysis of Projective Determinacy; see (Rittberg 2015) for details. This exploration has delivered arguments (but no generally accepted proof) that the Axiom of Determinacy, AD, holds in L($\mathbb{R}$). The assumption that AD holds in L($\mathbb{R}$) features below.

The second model is a technical generalization of L(ℝ). Notice that L(ℝ) is set-theoretically the same as $L(V_{\omega+1})$. The second model is $L(V_{\lambda+1})$, whereby λ is a cardinal such that there is an elementary embedding from $L(V_{\lambda+1})$ into itself with critical point below λ. As Koellner remarks, this embedding condition is "the strongest large cardinal axiom that appears in the literature" (Koellner 2013). The model $L(V_{\lambda+1})$ has thus far not received much attention from the general set-theoretic community (but this may be changing with Woodin's work).

Assuming that AD holds in L(ℝ), and thus in $L(V_{\omega+1})$, set theorists can prove that ω^+, that is, the successor cardinal of ω, is a measurable cardinal in $L(V_{\omega+1})$: see (Rittberg 2015) for more technical details. Similarly set theorists can prove that λ^+ is a measurable cardinal in $L(V_{\lambda+1})$ under the embedding condition. Woodin and Koellner now propose to study these two models under the assumption of versions of the V=Ult-L axioms. If further similarities of the structure theories of these models are observed, then this counts in favor of the version of the axiom. Diverging structure theories count as evidence against the version of V=Ult-L under consideration.

A negative convergence result has already been obtained. Woodin could show that under the assumption of one version of V=Ult-L the structure theories diverge (Koellner 2013). According to the convergence argument, this is evidence against this version of V=Ult-L.

The search for similarity leads to, as Koellner terms them, a "list of definite questions" (Koellner 2013). These questions are hard mathematical questions that will require considerable effort to answer, but they are answerable: "independence is not an issue" (ibid.). The "specter of undecidability," which resurfaced in the wake of the choice-problem between the different versions of V = Ult-L, seems finally to be tamed. It is not yet banished, as the analysis of the convergence of structure theories is not yet completed, but the set theorists are now in possession of a method that could potentially banish the specter for good.

This completes my presentation of the Ultimate-L argument. To quickly recap, because Woodin is a monist, the undecidability situation set theorists are currently facing is a "dilemma" for him. Woodin embarks on a research project to overcome this problematic situation. He realizes that an L-like structure that can accommodate a supercompact cardinal can accommodate essentially all large cardinals. Furthermore, the axioms stating that the universe of sets is such an Ultimate-L resolve the undecidability issue. The choice problem between the different versions of V=Ult-L is met with the convergence argument. In short, Woodin's monist understanding of the undecidability situation is a driving force of an elaborate (and by now over 10 years long) research project. Metaphysical belief is a driving force for mathematical activity here.

It is worth remembering at this point that metaphysical thought is not prior to mathematical activity. Woodin has come to his monist point of view in part because of mathematical results; he stresses the astonishing linearity of the large cardinal hierarchy, for example. The claim of this chapter is that metaphysical views and mathematical research develop in tandem and may partially influence each other.

This partial influence of metaphysics and mathematical research takes concrete form in the proposal to employ the V=Ult-L axioms and the convergence argument to decide the set-theoretic pluralism issue. Recall that the convergence argument tests the different versions of the V=Ult-L axioms by picking one such version and, under the assumption that this version of the axiom holds, investigates the structure theories of two set-theoretic structures. This leads to a list of hard-to-answer-but-answerable questions; undecidability is not an issue.

> if the answers converge then one will have strong evidence for new axioms settling the undecided statements (and hence non-pluralism about the universe of sets); while if the answers oscillate, one will have evidence that these statements are "absolutely undecidable" and this will strengthen the case for pluralism. (Koellner 2013)

In (Rittberg 2016a) I called this *mathematical pull*. Mathematics and metaphysics are set up in such a way that by doing more mathematics, namely by answering those hard-to-answer-but-answerable questions, cases for metaphysical positions can be made. The hyperbolic enthusiast might say that we can calculate an answer for the set-theoretic pluralism issue. A more sober formulation would stress that this is Koellner's proposal, that it relies on the V=Ult-L axioms and hence also on the assumptions that are part of the Ultimate-L argument, among which are Woodin's monist inclinations. Relevant for this chapter is that this is an argument by mathematicians, made in the context of a debate had by mathematicians, on how a metaphysical debate might be influenced by mathematical results. My point is that (future) mathematical research is set up to pull metaphysical views here.

In the next section I introduce Hamkins' contribution to the set-theoretic pluralism debate. My aim is again to show the reciprocal relationship between metaphysical beliefs and formal mathematical activity.

3 Hamkins' Multiverse View

Joel David Hamkins is a prolific set theorist and active participant in the debates of the mathematical community; for example, he is the top-rated user by reputation-score on the mathematics community website mathoverflow.net (as of June 2020). He was Woodin's PhD student and has maintained amicable relations with his former supervisor which have resulted in several joint publications, including (Hamkins and Woodin 2005, 2017; Hamkins et al. 2008).

Hamkins' primary published contributions to the pluralism debate are his (2012, 2014, 2015) and he has given numerous presentations and contributed online content on the issue. The 2012 paper begins by acknowledging that set-theoretic monism, or the "universe view" as he calls it, "is the commonly held philosophical position" (Hamkins 2012, p. 416) among set theorists (but he gives no evidence to support this empirical claim). The (2012) paper is an argument against this view. In (2015) and (2014) Hamkins focuses on specific arguments made in (2012) and develops them further.

Hamkins' arguments rely on the experience set theorists have with various models of set theory. Set theorists can build set-theoretic models and study them. The inner model program introduced in the last section does this, for example. The general methodology to build a set-theoretic model is to start from a given model and build a new model from there. Forcing is a well-known method to build such new models, looking at submodels such as L or HOD is another. The structure theory of the new model, that is, those statements that are true in the new model, is usually different from the structure theory of the model one has started with. The prominent example comes from Gödel's proof that CH is true in L and Cohen's proof that CH is false in a forcing extension of L. Indeed, set theorists have become very good at manipulating their constructions of the new models to ensure that certain targeted propositions are true or false in the newly built model. This is how the independence phenomenon is studied: start with a model in which a proposition is true (or false) and build a model in which it is false (or true). As Hamkins (2012, p. 418) puts it, "set theorists build models to order."

The orthodox monist interpretation of these many set-theoretic models is roughly this. The true universe of sets is the model of set theory which contains all sets. Every model of set theory "believes" that it contains all sets, this is part of what it means to be a model of set theory. (It is common practice in set theory to ascribe agency to models; for example, Jech (2006). I follow this convention here, using inverted commas to highlight such use.) However, the monist maintains, there is only one true model, the so-called *universe of sets*. All other models are "mistaken" and "overlook" some sets. For example, Gödel's constructible universe "overlooks" all non-constructible sets. The monist may find relevance and joy in the study of these models, as happens in the inner model program, but they are seen as studies restricted to certain kinds of sets (those that are in the model), rather than all sets (that "live" in the universe of sets). In this sense there are many set-theoretic models that "live" inside the one true universe of sets, according to the monist.

Hamkins argues that because set theorists have such extensive experience with diverse set-theoretic models, the ideological stance that one of these models enjoys the privileged status of being the "true universe of sets," that is, monism, has to be given up. For him all set-theoretic models are universes in their own right. The set theorists' experiences with these models indicate "that there are diverse distinct concepts of set, each instantiated in a corresponding set-theoretic universe, which exhibit diverse set-theoretic truths" (Hamkins 2012, p. 416). The collection of all set-theoretic models/universes constitutes what Hamkins calls the "multiverse". Woodin (2011b), Steel (2014), and Väänänen (2014) have introduced different conceptions of a multiverse, which are more limited than Hamkins'.

To highlight, Hamkins argues that the intimate understanding of certain formal mathematical results, those extensive experiences with diverse set-theoretic models, puts pressure on the monist orthodoxy. The argument is that because of formal mathematical results a certain metaphysical position ought to be given up. Hamkins treats formal mathematical results as evidence and lets them shape his metaphysical views here.

For Hamkins, the set-theoretic knowledge about independence constitutes an answer to questions which are undecidable from the ZFC axioms, such as the CH:

> On the multiverse view the continuum hypothesis is a settled question, for the answer consists of the expansive, detailed knowledge set theorists have gained about the extent to which the CH holds and fails in the multiverse, about how to achieve it or its negation in combination with other diverse set-theoretic properties. Of course, there are and will always remain questions about whether one can achieve CH or its negation with this or that hypothesis, but the point is that the most important and essential facts about CH are deeply understood, and it is these facts that constitute the answer to the CH question. (Hamkins 2012, p. 3)

This reminds of Rouse's point about scientists interpreting the situation they are in differently. Where Woodin sees "specters" and "dilemmas," Hamkins sees answers to set-theoretic questions.

According to Woodin there is a paucity to the current set-theoretic machinery because it cannot fully capture the (one true) universe of sets. For Hamkins there is no paucity in these methods. On the contrary, these methods help to reveal that there are in fact multiple set-theoretic realities. Hamkins needs to argue that all those models the set-theoretic machinery can produce deserve to be considered as such set-theoretic realities- it is worth recalling here from the introduction that both Woodin and Hamkins agree that mathematical objects exist; Hamkins (2012, p. 417) calls it a "Platonic sense," but Hacking (2014) would use lower-case p). Hamkins (2012) starts by engaging with the counterargument that there are no forcing extensions of the true universe of sets V.

For a nontrivial forcing extension of a set-theoretic model M, one needs to find a special set G, called an M-generic *filter*, which is not in M. Therefore, to find a forcing extension of the true universe of sets V, one needs to find a V-generic filter G which is not in V. But V is supposed to be the collection of all sets, thus G is in V by assumption. Hamkins calls it a "catechism" (2012, p. 420) of monism that "there are no V-generic filters." He proposes to view the matter rather like moving from real to complex numbers. There is no solution to the square root of -1 in the real numbers, but once one moves to an extension of the real numbers, the complex numbers, such a square root can be found. There is no (non-trivial) V-generic filter G in the conception of sethood embodied by V, but such a G can be found in a new and broader conception of sethood, that is, a new model. As Koellner (2013) points out, this new model is non-standard because it is either countable, or not two-valued, or neither transitive nor well-founded. Despite this, Hamkins even suggests at times that such bigger models are "better" (2012, p. 438), but his argument for pluralism does not hinge on this value-judgment.

Hamkins also draws an analogy between set theory and geometry. According to his presentation, non-Euclidean geometries were considered to be curiosities and mere reinterpretations of concepts within Euclidean geometry. With time came understanding and experience with non-Euclidean geometries and they became accepted as geometrically meaningful. "The situation with set theory is the same"

Hamkins (2012, p. 426) suggests. For a set theorist disagreeing with this analogy, see (Magidor 2012). For a philosophical assessment of the analogy see Maddy (2011).

We saw in the last section that Woodin's monism is a driving-force for his mathematical research project on Ultimate-L. Similarly, Hamkins' pluralism gives relevance to two mathematical research projects he is engaged in, the *modal logic of forcing* and *set-theoretic geology*. I now turn to a discussion of these projects.

Forcing enjoys a special status among the methods set theorists employ to build set-theoretic models because it has proven to be very fruitful (Džamonja and Kant 2019). Today forcing is widely applied in set-theoretic proofs. The method is even influential enough to warrant the philosophical *Forcing Project*, led by Carolin Antos, which explores the philosophical implications of forcing as a mathematical method. This is much aligned with the tenet of this paper that mathematical activity and philosophical thought intertwine and may inform each other. Via forcing one can build from one model of set theory, the ground model, another model of set theory, the forcing extension. This relates these two models: one is the extension of the other. Relational structures can be studied via modal logics (Blackburn et al. 2001), which gives rise to the investigation of the modal logic of forcing. The set-theoretic geology project inverses the extension-relation of forcing: instead of looking "outwards" to find forcing extensions one looks "inwards" to find ground models.

Modal logics make use of two logical symbols: diamond, often interpreted as "it is possible that. . .," and box, often interpreted as "it is necessary that. . ." Hamkins (2003) proposes to interpret these modal operators as "it is forceable that. . ." and "in every forcing extension. . ." respectively. For example, Cohen showed that there is a forcing extension of Gödel's constructible universe L in which non-CH holds and thus "diamond non-CH" is true in L.

Hamkins (2003) introduced this interpretation of the operators in connection with a certain maximality principle. In 2004 Hamkins and Löwe started their collaboration on the modal logic of forcing (Löwe, personal commutation 2020). They uploaded a preprint to arxive.org in 2005, which was later published as (Hamkins and Löwe 2008), neither of which mentions the term *multiverse*. As Löwe recalls it (personal communication 2020), he started thinking about the topic in multiverse terms only in 2009. A few years earlier Woodin (2004) had introduced what he called the *generic multiverse* (see last section) in a talk at a conference in Copenhagen. Hamkins' first mention of the term *multiverse* in print seems to be (Hamkins 2009), which refers to Woodin's (2004). Hamkins and Löwe (2013) is the first contribution to the modal logic of forcing project that explicitly endorses a multiverse perspective, and they refer to a draft version of (Woodin 2011d) as a source for the terminology.

As this timeline shows, Hamkins and Löwe did not have a fleshed out multiverse view when they began work on the modal logic of forcing project. My claim is that metaphysical positions and mathematical activity develop in tandem and may inform each other. At this point of this chapter, my interest is in making visible how pluralism gives relevance to the set-theoretic geology and the modal logic of forcing projects.

Some set-theoretic propositions can be switched on and off via forcing like a light-switch. The CH is an example. For every model in which CH holds there is a forcing extension in which CH fails, and for every model in which CH fails, there is a forcing extension in which CH holds.

Other set-theoretic propositions can be forced to be false, that is, there is a model in which the proposition holds which has a forcing extension in which the proposition is false, but once they are false they cannot be recovered by forcing. They are like buttons that, once pushed, cannot be unpushed. The axiom stating that every set is constructible in Gödel's sense, $V = L$, is such an axiom. It is true in L but false in, for example, Cohen's forcing extension of L, and there is (provably) no forcing extension of Cohen's forcing extension of L in which $V = L$ is true again.

Hamkins and Löwe (2008) show that every set-theoretic proposition is either such a switch, a button, or the negation of a button. This allows them to prove that forcing forms a modal logic called S4.2, the modal logic describing finite pre-lattices. More precisely, S4.2 is sound and complete with respect to the class of Kripke-frames that form a finite pre-lattice. For a detailed formal presentation of Hamkins' and Löwe's result see (Rittberg 2010). This result, and the methods employed to obtain it, is at the core of the modal logic of forcing project. Further relevant contributions to this project include (Inamdar and Löwe 2016; Block and Löwe 2015; Hamkins et al. 2015; Hamkins and Löwe 2013; Inamdar 2013; Friedman et al. 2018).

This completes my brief presentation of the modal logic of forcing project. I now turn to the set-theoretic geology project.

The set-theoretic geology project inverses the extension-relation of forcing. Where forcing starts with a ground model M and moves to a forcing extension M[G], in the set-theoretic geology project one starts with a model N and asks if there is a ground model M and a forcing such that N is the forcing extension M[G]. Metaphorically speaking, the set-theoretic geology project strips away the forcing-residue from a model (Hamkins 2012, pp. 446–447).

In general, the ground M is not unique, which gives rise to the notion of a *bedrock*, a minimal ground. Reitz (2006, 2007) showed that there are models that do not have a bedrock, which in turn gives rise to what Hamkins (2012, p. 444) calls "the principal new set-theoretic concept in [set-theoretic] geology": the *mantle* is the intersection of all grounds.

A "fundamental question" (Hamkins 2012, p. 445) of the set-theoretic geology project was whether the mantle is a model of ZFC. In what Hamkins calls a "breakthrough" (in numerous talks on set-theoretic geology, abstracts for which can be found on his http://jdh.hamkins.org/), Usuba (2017) proved the strong directed grounds hypothesis, which implies that the mantle is indeed a model of ZFC. Usuba's result answered many, but not all, central questions of the set-theoretic geology project and raised new ones. The mathematical introductory paper to the set-theoretic geology project is Fuchs et al. (2015). Further contributions to the project include Habič et al. (2019), Davis (2016), Reitz (2006, 2007).

Hamkins (2012, p. 440) calls the modal logic of forcing and the set-theoretic geology projects "multiverse-inspired mathematics" and points out that "the multiverse view in set theory leads one to consider how the various models of set theory

interact, or how a particular world sits in the multiverse." Words such as "inspire" and "leading to" suggest that the philosophical view was there before the mathematical projects were started. As pointed out above, this temporal order may not suitably reflect the actual happenings to count as good history-writing. To read Hamkins as a historian doing a questionable job is, I suggest, uncharitable. Instead I propose to read him as pointing out that his pluralist philosophy gives relevance to the two mathematical projects. My argument is that the Hamkins-style pluralist can recognize the value of the two projects in ways monists generally do not.

Johansen and Misfeldt (2016, p. 262) remark on what they call the *value of recognizability*:

> The value of recognizability prescribes that the mathematical community or a relevant subgroup thereof can recognize your work as interesting and important, and it is enacted by choosing problems and areas of work that other mathematicians find attractive and can identify themselves with... The subjection to recognizability contrasts with the idea of mathematics being rational and democratic, and also with the idea that mathematics is a landscape to be investigated. As a mathematician, it is not sufficient to obtain mathematical results; you must obtain results that others in the mathematical community are able to recognize [as interesting and important].

In the context of Hamkins-style pluralism, the two projects are interesting and important. The Hamkins-style pluralist holds that there are many different set-theoretic universes, all of which are members of the set-theoretic multiverse. This raises questions about the structure of this multiverse, that is, about how the set-theoretic universes are related to one another in the set-theoretic multiverse, how they "sit in the multiverse" to cite Hamkins (2012, p. 440) again. One of the many ways these universes relate to each other is via forcing; other examples include inner model constructions. The modal logic of forcing and the forcing geology project study this forcing-relation, which make them interesting and important explorations of the multiverse to the Hamkins-style pluralist.

The monist lacks a clear story why the two projects are interesting or important. Unlike Woodin's hard-to-answer-but-answerable questions, they do not aide monism in finding a resolution to the current undecidability-situation. Arguably, very few set-theoretic questions currently explored have this explicitly monist goal, so this may be too much to ask. But there is also no other obvious connection of the two projects with those set-theoretic problems which are currently regarded as relevant, important, and interesting by the set-theoretic community at large. The point is that the two projects explore new questions which can make it hard to recognize their relevance. The projects do not initially promise new consistency results, insights into structure theories of known set-theoretic models that would generally be considered as deep, or fresh insights into definability for example. Without a Hamkins-style view on mathematics, the two projects may seem neither interesting nor important, that is, they lack in value of recognizability.

As so often with accounts of a mathematical practice, lived realities do not adhere to neat accounts. In an interview with Kant, Džamonja remarked that "one can do the same mathematics independently of one's philosophical view" (Džamonja and Kant 2019, p. 19). She is right about this and some set theorists have contributed to the two projects without drawing on a Hamkins-style outlook on set-theory. For example, Gitman (a former PhD student of Hamkins) pointedly remarks that "It took four decades since the invention of forcing for set theorists and to ask (and answer) what post factum seems as one of the most natural questions regarding forcing. Is the ground model a definable class of its set-forcing extensions?" (Gitman and Johnstone 2014). This question was independently answered by Laver (2007) and Woodin (2004), and Hamkins (2012, p. 443) presents their results as a starting point for the set-theoretic geology project. That is, Laver and Woodin were interested in questions relating to the set-theoretic geology project. Another example is Golshani's and Mitchell's (2016) contribution to the modal logic of forcing project. They explore what they call the "Hamkins-Löwe property," showing that even though the project explores new questions, there are points of connection to issues that are of concern to a general set-theoretic audience.

I believe Džamonja's remark mentioned above to be correct. My point is not that proponents of one philosophical view cannot or do not participate in the mathematical projects driven by differing philosophical views. There is indeed much overlap, such as the already mentioned collaborative works of Woodin and Hamkins. But some projects, such as the search for an Ultimate-L or the modal logic of forcing and set-theoretic geology projects, are driven by philosophical interests in a way that discourages mathematicians of a differing philosophical bent to participate. My point is not that these mathematicians cannot participate in such projects, my point is that they rarely do. (I borrow this formulation from Netz (1999, 2017), who argues against the historiographical strategy of conceptual impossibility: "they did not do X because they did not have the concept." He argues: "it's not that they couldn't: it's just that, more often than not, they didn't" (Netz 2017, p. 38).)

I argued that in the context of Hamkins-style pluralism the two projects are recognizably relevant. And indeed, many of the contributors to the two projects are Hamkins' former students (e.g., Jonas Reitz, Victoria Gitman, George Leibman) or set theorists whose philosophical view aligns with Hamkins' (e.g., Benedikt Löwe)- Löwe's views on set-theoretic pluralism remain unpublished; I know of them mostly through personal communication and presentations he gave, for example, at the *FOMUS* conference in Bielefeld 2018. There are other motivations to pursue these projects as well, but they have led to few contributions to the projects. In this sense then is Hamkins-style pluralism a (but possibly not the only) driving force of the modal logic of forcing and the set-theoretic geology projects.

Hamkins-style pluralism gives relevance to the two projects. That is, a philosophical outlook on set theory shapes what counts as relevant, important, or interesting mathematical research. A philosophical outlook shapes mathematical activity here.

4 Concluding Remarks

The case studies presented in the last two sections have shown some of the reciprocal relationship between the mathematical activity of Woodin and Hamkins and the metaphysical positions the two set theorists endorse. I briefly summarize the relevant points here. I then turn to other mathematical practices, such as geometry, and provide some suggestions why it is reasonable to expect that mathematical activity and metaphysical positions shape each other in these practices as well. If I am right about this, then metaphysical views are an integral part of mathematical practices.

Woodin is a monist. Monism is the orthodox view in set theory, which relieves Woodin from providing detailed argument for the position. He focuses on resolving the problem monists see in the current undecidability situation in set theory. Monism thus motivates Woodin's (current) proposal to engage with this "specter of undecidability." He proposes the Ultimate-L argument. His monist inclinations shape his mathematical activity. The key insight is that if an L-like model which can accommodate a supercompact cardinal could be built, then this model would accommodate essentially all large cardinals. It would be an Ultimate-L. No such model has yet been built, but Woodin has offered many different set-theoretic propositions stating that the universe of sets is such an Ultimate-L: the V=Ult-L axioms. These axioms conflict with one another, and Koellner and Woodin have proposed the convergence argument to decide among them. This convergence argument feeds back into the set-theoretic pluralism debate. If there is convergence (of the relevant structure theories), then this would be evidence for monism. But should there be divergence, then pluralism would score a win. This convergence argument relies on hard-to-answer-but-answerable formal mathematical questions. That is, producing new mathematical results can, via the convergence argument, impact a metaphysical debate the set theorists are currently having. Mathematical activity is set up to pull the metaphysical debate.

Hamkins is a pluralist. He needs to argue against the reigning monist orthodoxy, which he does by pointing to the experience set theorists have with various set-theoretic models. These experiences come from mathematical results and mathematical activity involving these results. Thus, Hamkins' arguments draw on mathematical activity (and its results) to make the case for pluralism; mathematical activity shapes the metaphysical view. Hamkins-style pluralism gives relevance to the *modal logic of forcing* and the *set-theoretic geology* projects because it provides motivations to pursue these projects. Metaphysical thinking gives relevance to mathematical activity here.

As I have stressed repeatedly in this chapter, neither metaphysical belief nor mathematical activity is prior to the other. There is no chicken-or-egg problem here but a reciprocal relationship in which both sides may inform and shape each other. This challenges the distinction between intrinsic and extrinsic justifications for axioms often made in the debate about axiom choice in set theory (Maddy 2011; Parsons 2008; Gödel 1947). Set-theoretic axioms are intrinsically justified, according to the proponents of this distinction, if they "unfold the content of the concept of set" (Gödel 1947). Extrinsic justifications of an axiom are its success, its

fruitful and verifiable consequences. Intrinsic justifications thus play on metaphysical beliefs, extrinsic justifications on the results of mathematical activity. The distinction between intrinsic and extrinsic justification hence relies on a demarcation between metaphysical beliefs and mathematical activity. I have argued in this chapter that rather than a clear demarcation there is a reciprocal relationship between metaphysical beliefs and mathematical activity. They inform and shape each other, and this challenges the intrinsic/extrinsic distinction.

There are many mathematical practices and in this chapter I have thus far only engaged with one, set theory. In fact, engagement with set theory is limited to a detailed study of two set theorists. My hope is that the numerous pointers to other set theorists in this paper provide enough indication on where to look to suggest that my claims extend to the practice as a whole. I now want to briefly suggest that it is reasonable to expect that in mathematical practices other than set theory mathematical activity and metaphysical beliefs inform each other as well.

First off, we may simply take the mathematicians seriously who profess to the relevance of philosophical thought to their mathematical activity. Fields medallist Terrance Tao aptly titled his (2018) "There's more to mathematics than rigour and proof." Tao speaks of a post-rigorous stage in which mathematicians are guided in part by what he calls "solid intuition." Such intuitions, I suggest, are partially shaped by the mathematician's metaphysical views. For example, Hamkins' intuitions about set-hood are different from Woodin's. For Hamkins "every countable transitive model of set theory can be continued to a model of V = L" (2012, p. 439) by extending the class of ordinals. This makes no sense for Woodin-style monism: the class of ordinals (in the true universe of sets) cannot be extended (because there is nothing more than "all of them"). Timothy Gowers, another Fields medallist, speaks of two cultures in mathematics. "I mean the distinction between mathematicians who regard their central aim as being to solve problems, and those who are more concerned with building and understanding theories" (Gowers 2000). There are different philosophies at work here. Even more such philosophies are explored in terms of narrative in (Doxiadis and Mazur 2012); Alexander's contribution to the volume (pp. 20–64) is particularly insightful on the point I am making here.

Understood this broadly it is fairly obvious that philosophical thought is part of mathematical research. In this chapter I have made the narrower claim that metaphysical beliefs about mathematical objects of study, sets in this case, stand in a reciprocal relationship with mathematical activity. A similar claim has been put forward by Chang about scientific activity. He argues that "if we want to engage in a certain epistemic activity, then we must presume the truth of some particular metaphysical principles" (Chang 2008, p. 113). Given that a convincing argument to the effect that there is a relevant difference between science and mathematics is still lacking, I take the points of philosophers of science like Chang to support the expectation that metaphysical beliefs play a role in mathematical practices other than set theory as well.

A promising place to look for a reciprocal relationship between mathematical activity and metaphysical beliefs is geometry. Bos (2001, p. 3) reminds us that in what he calls Classical Greek geometry "geometrical figures were 'known' or

'given' if they could be *constructed* starting from elements that were considered given at the outset." Classically, a geometric object is considered 'constructed' if it can be obtained from some given points by ruler and compass constructions; see Manders' seminal (2008) for detailed discussion of subtleties brushed over here. But other possible ways to construct geometric objects where always known.

> Plato himself reproached Eudoxus and Archytas and Menaechmus for setting out to remove the problem of doubling the cube into the realm of instruments and mechanical devices, as if they were trying to find two mean proportionals not by the use of reason but in whatever way would work. In this way, he thought, the advantage of geometry was dissipated and destroyed, since it slipped back into the realm of sense-perception instead of soaring upward and laying hold of the eternal and immaterial images. (Plutarch 1961, pp. 121–123)

What is at stake here is the metaphysical question when a geometrical object counts as constructed or given. Bos' (2001) is an insightful analysis of some of what Plutarch called "mechanical devices" and their usage. It reveals that some mathematicians have considered geometrical objects as constructed when they can be obtained by means of these "mechanical devices," such as marked ruler or Neusis constructions. Such constructions motivated mathematical activity which was sufficiently different from ordinary ruler-and-compass geometry that the two were kept apart: mainstream geometry constructed via ruler and compass, other geometrical practices allowed other tools of construction. Some mathematicians felt bound to one way of doing geometry, others worked in multiple idioms (Bos 2001).

Geometry has also been done by paper folding (Friedman 2018). This off-loads permissible constructive moves to the physical realities of paper (Friedman and Rittberg 2019). For mathematician Sundara Row, this gives proofs by paper folding an undoubtable immediacy. This reflects in his writing. He relies heavily on pictures of folded paper and uses formal syntactic presentations sparingly. Other mathematicians, such as Piazzolla Beloch, forego actual foldings of paper altogether and rely entirely on formal syntactic representations of folds in their proofs. My suspicion is that Row's and Belloch's metaphysical views shape how they conduct their mathematical activities.

Perhaps geometry is as easy a case as set theory to make visible the reciprocal relationship between metaphysical thought and mathematical activity in a mathematical practice. Much harder, I believe, would it be to make visible how this reciprocal relationship plays out in some other mathematical practices, such as number theory (the work of Ed Nelson may be a starting point). The history of the conception of number as well as historical works on mathematical practices whose motivations are remarkably different to those of contemporary mathematics (Chemla 2012; Kümmerle 2019) may be good starting points. But such studies would still lack some indication of how metaphysical beliefs shape and are shaped by *contemporary* mathematical activity in number theory. I know of no good example. Perhaps there is large-scale agreement among contemporary number theorists on relevant matters. It could be that such a state of affairs simply hides instances where mathematical activity is shaped by metaphysical thought. Or it could be evidence

that research activity in number theory is indeed free of any metaphysical presuppositions. I find the latter highly unlikely.

Metaphysics is not influenced by mathematics, nor is mathematics influenced by metaphysics. There is not one thing influencing the other (as e.g., Hamkins has suggested during his CLMPST presentation in Prague 2019; slides available at http://jdh.hamkins.org/wp-content/uploads/Set-theoretic-mereology-as-a-foundation-of-mathematics-CLMPST-Prague-2019.pdf (accessed June 2020). Rather, metaphysical thinking and mathematical research activity are both ordinary aspects of the participation in a mathematical practice (or at least: set-theoretic practice) and partially shape each other. In this section, I have suggested that we might have expected this, that the message of this chapter is ultimately obvious. The interesting part is, I believe, in the *how* mathematical activity and metaphysical thought interact. In this chapter, I have explored how this happens in set-theoretic practice.

Acknowledgments I would like to thank Carolin Antos, Neil Barton, Deborah Kant, Juliette Kennedy, Daniel Kuby, Benedikt Löwe, and Deniz Sarikaya for helpful remarks on draft versions of this chapter. Research for this chapter has been funded by the Centre for Mathematical Cognition at Loughborough University and the Research Foundation - Flanders (FWO), project G056716N.

Abstract

Definitions are traditionally seen as abbreviations, as tools for notational convenience that do not increase inferential power. From a Philosophy of Mathematical Practice point of view, however, there is much more to definitions. For example, definitions can play a role in problem solving, definitions can contribute to understanding, sometimes equivalent definitions are appreciated differently, and so on. This chapter reviews the literature on definitions and (to a certain extent) concepts in mathematical practice. It is structured according to four themes through which definitions (and concepts) in mathematical practice have been studied. These themes concern (1) the nature of definitions, (2) whether and how concepts evolve, (3) definitions and concepts from a communal perspective, and (4) different values relating to definitions and concepts.

1 Introduction

Definitions are a central part of mathematics and mathematical practice. Traditionally, they have been studied in logic for their inferential role (see Belnap 1993). However, the role of definitions in mathematical practice goes beyond this. As Tappenden (2008a) remarks, "mathematicians often set finding the 'right'/'proper'/'correct'/'natural' definition as a research objective and success – finding the 'proper' definition – can be counted as a significant advance in knowledge" (Tappenden 2008a, p. 256).

Understanding proofs in practice is a prominent topic in the philosophy of mathematical practice. To give an imcomplete overview, there is literature on the various functions of proofs (De Villiers 1990; Baldwin 2018; Dawson 2006), on the difference between the ideal conceptions of proofs and proofs in practice (Andersen 2018; Larvor 2012; Hamami 2019), on virtues of proofs (Detlefsen 2008; Inglis and Aberdein 2015; Kleiner 1991), and on proofs and the peer review process (Andersen 2018; Frans and Kosolosky 2014; Geist et al. 2010). By contrast, definitions in practice have not been studied systematically as of yet. This does not mean that definitions have not been investigated at all. In fact, there is a reasonable literature on definitions in mathematical practice. Usually, however, the main point of focus in that literature is not to get a better understanding of definitions in practice, but to discuss a different topic in which definitions are a particular case. As a result, definitions in mathematical practice have been discussed, but not systematically, and it is therefore difficult to navigate through the existing literature that relates to definitions in mathematical practice.

This chapter is an effort to make the literature on definitions more accessible by reviewing and organizing the literature on definitions *in mathematical practice* (from now on referred to as simply "definitions"). Such an overview can help structure future research, in the hope of obtaining a better understanding of definitions in practice.

The chapter will also discuss the notion of "concept." This is because definitions and concepts are intricately related. One of the main functions of definitions is to specify or introduce a concept. In that sense, definitions are sometimes evaluated on the basis of the concept they specify. Vice versa, mathematicians try to understand certain concepts, and definitions can serve as means to do that. In that sense, some definitions are considered better than others for understanding a concept. In short, to meaningfully discuss definitions, one also needs to take concepts into account to a certain extent.

This chapter is outlined as follows. It starts with a brief discussion of the relation between definitions and concepts. This discussion serves two purposes. First, it helps to determine to what extent literature on concepts should be included in this review

(as the literature on concepts is vast and goes well beyond the scope of discussing definitions in practice). Second, the term "definition" is used by various authors, possibly meaning different things. Similarly, the usage of the term "concept" varies slightly across authors. By fixing a meaning for these terms, one can compare the usages.

After these initial remarks, the literature on definitions and concepts in mathematical practice will be discussed. The overview is structured according to four themes that can be identified in the literature. These themes concern (1) the nature of definitions, (2) whether and how concepts evolve, (3) definitions and concepts from a communal perspective, and (4) different values relating to definitions and concepts. N.B. Definitions are also studied in the context of mathematics education. However, a discussion of this is beyond the scope of this chapter. The interested reader is referred to (Ouvrier-Buffet 2013), which includes a summary of the mathematics education literature on definitions. This chapter is concluded with some remarks on the relation between the different themes.

2 The Relation Between Definitions and Concepts

Before looking into the literature regarding definitions, it is useful to first get an idea of the distinction between definitions and concepts. Unfortunately, the discussion regarding definitions and concepts *in general* is too diverse to find an uncontroversial description of both (Belnap 1993; Gupta 2019; Robinson 1954; Cappelen and Plunkett 2020; Margolis and Laurence 2019). For the purpose of this chapter, it suffices to take the notion of "definition" to refer to linguistic entities that specify the meaning or usage of a term. When it comes to the ontological status of concepts, there are also various competing theories (Margolis and Laurence 2019). The relation between definitions and concepts as used in this chapter is that *definitions are linguistic entities that give rise to concepts, mental or otherwise, and in doing so they can concur with or differ from pre-existing/intended concepts.*

As an illustration, consider the example of prime numbers, which is also considered in (Tappenden 2008a) for different purposes. For the natural numbers, one can define prime numbers through the following definitions:

- A natural number P is prime if and only if the only divisors of P are 1 and P.
- A natural number P is prime if and only if for every pair of natural numbers a, b we have that if P divides ab, then P divides a or P divides b.

These are different definitions which give rise to the same concept of "prime number."

Another example can be found in Lakatos' *Proofs and Refutations* (2015). In this well-known work, which will be discussed later in more detail, the notion of a polyhedron is investigated: What is a polyhedron? Several definitions are discussed, and they are often evaluated on the criterion of whether they concur with some intended concept of what a polyhedron is.

In the following, the terms "definition" and "concepts" are used in the way described above. However, some of the authors, whose work is discussed in this chapter, also use these terms, possibly meaning different things. What is meant with the term is usually clear from the context. However, when I want to stress the meaning from the above formulation, I will write *definition* and *concept*.

To illustrate the intricacy of the relation between the notions of *definition* and *concept*, and to show the use of distinguishing between *definition* and *concept*, one can look at the history of the topological notion of compactness (Raman-Sundström 2015). Nowadays, compactness usually refers to open-cover compactness (X is compact if each open cover U has a finite subcover). For metric spaces, the notion of open-cover compactness is equivalent to so-called sequential compactness (a space X is sequentially compact if every sequence xn has a subsequence that converges in X). For topological spaces in general, this is not the case. This means that in some contexts, different *definitions* can lead to the same *concept*, whereas their generalizations can give rise to different *concepts*.

Furthermore, Raman-Sundström (2015) describes definitions of compactness that are analogous to the definition of sequential compactness. In other words, these versions are equivalent to open-cover compactness but, in some way, do justice to the formulation of sequential compactness in terms of convergence and sequences. One of these generalizations is in terms of nets. Whereas sequences are usually indexed by the natural numbers (0, 1, 2, 3, etc.), nets allow elements to be indexed by a far broader class of sets. By using a notion of convergence that relies on the notion of net, one can transform the formulation of sequential compactness in such a way that the result is equivalent to open-cover compactness. In conclusion, it can occur that different *concepts* have analogous *definitions* (in this case, the definition of sequential compactness is analogous to the definition of compactness in terms of nets). For more detail on the history of compactness, the reader is referred to (Raman-Sundström 2015).

3 Theme I: The Nature of Mathematical Definitions

As emphasized in the above relation between definitions and concepts, a definition is a linguistic expression, but not every linguistic expression is a definition. Therefore, the question is: What do we expect definitions to do? What differentiates definitions from linguistic expressions in general? In this section, three points of view on this issue are discussed: the traditional, the heuristic, and the work of Ouvrier-Buffet (2013).

The traditional view and the heuristic view are discussed by Cellucci (2018). He describes the traditional view as a combination of five statements (that he traces back to the works of Frege):

> (1) *A definition merely stipulates the meaning of a term* [. . .] (2) *A definition is an abbreviation* [. . .] (3) *A definition is always correct* [. . .] (4) *A definition can always be*

> *eliminated* [. . .] (5) *A definition says nothing about the existence of the thing defined* [. . .] (Cellucci 2018, p. 608).

Claim (3) is intended to mean that definitions are not right or wrong, as they are not assertions to begin with. Claims (2) and (4) are also discussed in the context of definitions in general (as opposed to mathematical definitions). They are referred to as the criterion of eliminability and conservativeness, respectively (Belnap 1993). (Note that, although item (4) uses the word "eliminated," it corresponds to the criterion of conservativeness and not to the criterion of eliminability.) The idea behind eliminability is that a definition can be formulated in terms that are already known. The criterion of conservativeness says that no new conclusions can be derived by introducing a certain definition. More precisely, let L be a language and T a theory. Then a definition consists of expanding the language, resulting in L', and adding sentences to the theory, resulting in T'. The criterion of elimination is then given by: with respect to theory T', every L'-sentence should be equivalent to an L-sentence. Conservativeness can be formulated as: For every L-sentence S, if S follows from T', then it should also follow from T.

Cellucci discusses the traditional view of mathematical definitions in order to refute it and to defend the heuristic conception of definitions. The latter fits within the heuristic conception of mathematics, which, although not a mainstream view of mathematics, has gained some traction (also see Goethe and Friend 2010). In this view, mathematical problem solving is not a matter of deductively proving statements from axioms, but a process in which problems are solved by the analytic method. This method consists of presenting plausible hypotheses that solve the problem. These hypotheses, in turn, are problems that need to be solved as well. This process of providing hypotheses for open problems can continue indefinitely. In that regard, Cellucci argues that definitions are hypotheses too. He formulates this as: "[a] definition is the hypothesis that there exists something which satisfies the condition stated in the definiens" (Cellucci 2018, p. 618).

Cellucci claims that the heuristic view of definitions is preferable to the traditional one because it can describe mathematics better. What he means with mathematics is "the 'real' mathematics of the 'real' mathematicians" (Cellucci 2018, p. 617). He contrasts this with formal conceptions of mathematics in which there is no room for the logic of discovery. According to Cellucci, the heuristic conception of definitions can explain various phenomena that are not explained by the traditional view of definitions, namely that: "(a) Two extensionally equivalent definitions of the same concept may have different heuristic values; (b) Definitions in mathematics are not starting points but arrival points in the solution to problems; (c) There is no circularity of definitions and theorems; (d) Many definitions are proof-generated; (e) Definitions in mathematics can be justified" (Cellucci 2018, p. 620).

Although Cellucci portrays both points of view as competitors, one might argue that they are complementary. The traditional view focuses on the inferential role of definitions and the context of justification, whereas the heuristic view zooms in on the preformal mathematics and the context of discovery. In that sense, both accommodate an investigation of mathematical practice, albeit of different aspects thereof.

Which view is more appropriate differs for each situation and depends on contextual factors.

The third view on the nature of definitions is offered by Ouvrier-Buffet (2013). She aims to understand the act of defining in order to develop didactical situations for mathematics students. To this end, she develops three conceptions of definitions: the Aristotelian, the Popperian, and the Lakatosian. In the following, only sketches of these conceptions are presented. The interested reader is referred to (Ouvrier-Buffet 2013) for a detailed discussion and references to her earlier work.

In the Aristotelian conception, definitions serve as tools for classification. One starts such a classification by looking at the set of objects and for specific differences within this set. Such an analysis should lead to an "aesthetic definition." Some principles for defining are logical, like that there should be no vicious circles, that previous terms should be defined, etc. Other principles in this conception include that redundancies and metaphors should be avoided and that the concepts, which are defined, should actually exist.

Whereas the Aristotelian conception considers definitions as tools for classification, the Popperian conception considers them useful for choosing between competing theories. In that sense, one can try to reduce the number of postulates of a theory and generate counterexamples. The principles that guide the defining process include, for instance, the resistance to refute theories and criteria for when one theory is better than another.

The Lakatosian conception combines aspects from the previous ones. According to this conception, definitions are employed to solve intramathematical problems (i.e., finding the domain of validity for a given theorem) and for classification. Some of the actions that guide the defining process are "generating examples and counterexamples" and consequently dealing with these counterexamples by the monster-barring and exception-barring (see Sect. 4).

These three conceptions are part of a model of the process of defining. This model also consists of different moments in the definition process ("in-action," "zero," "formalized," and "axiomatic") and an account of the type of problems that definitions can help solve. This model is used to create strategies for developing educational contexts for defining.

Finally, Ouvrier-Buffet (2015), on the basis of interviews with mathematicians, differentiates different types of definitions. For instance, she distinguishes between definitions that are temporarily used to shorten a talk from those that "remain and will belong in the public domain" (Ouvrier-Buffet 2015, p. 2216). Another distinction is made between working definitions that enable the mathematician to start investigating the object and the formal definition that one might arrive at later.

In conclusion, we saw various descriptions of what definitions are and what they (ought to) do. What all these views have in common, however, is that they see definitions as a device that links a term to a concept. This connection between a term and its concept is the subject of the following section.

4 Theme II: The Relation Between a Term and the Concept It Represents

Definitions are a way to assign to a term a concept/meaning. (Technically, concepts and meanings are different entities, but for the purpose of this chapter, I group them as one.) In this section, the relation between terms and their associated concepts is discussed. First, two points of view explicated by Schlimm (2012), regarding the status of this relation, are discussed: Is it fixed or is it subject to change? After establishing that, from a particular point of view, this relation can change over time, we turn to the work of Lakatos (2015) and Kitcher (1983), who discuss two ways in which this relation changes. Finally, the work of Tanswell (2018) is discussed. He not only demonstrates that this relation is not as definite as is sometimes assumed, but also suggests a way to steer conceptual change.

Although the title of Schlimm's *Mathematical Concepts and Investigative Practice* (2012) speaks of concepts, the article does not concern *concepts* (cf. Sect. 2), but the relationship between terms and what they refer to. Schlimm describes this in terms of whether "an object *a* falls under a concept *P*" (Schlimm 2012, p. 128). He then discusses two points of view regarding this relation: the Fregean view and the Lakatosian view. (Schlimm stresses that these perspectives are not per se those held by Frege and Lakatos, respectively, but that these are nonetheless inspired by their work.)

The Fregean view sees concepts as *definite* and *fixed*. That a concept is definite means that for every object, it is ontologically determined whether it falls under that concept or not. This does not suggest, however, that mathematicians themselves can immediately determine whether an object falls under that concept or not. That mathematical concepts are fixed means that if a term refers to a specific concept at one time, it does so always.

Mathematical concepts should be fixed, because otherwise logical deduction is not possible (Schlimm 2012). Arguments like "All *A*'s are *B*'s, this *X* is an *A*, therefore *X* is a *B*" might suffer if concept *A* changes between the first and second premise.

According to the Lakatosion view, by contrast, concepts are fluid and inexact: They may change, and sometimes it is not clear whether a certain object falls under the concept or not. One of the main motivations for this view is its ability to capture heuristic aspects of mathematics as well and not just the deductive parts.

Instead of arguing for either the Fregean or the Lakatosian view, Schlimm suggests that both of these descriptions are very useful in making sense of mathematical developments. He argues that "[i]n the history of mathematics many concepts were introduced informally and went through considerable changes, redefinitions, splittings, etc. However, other concepts were introduced by formal, determinate definitions from the start" (Schlimm 2012, p. 134). Accordingly, the Fregean and Lakatosian notion can complement each other.

One example that Schlimm discusses concerns the term "number." With the introduction of new number systems, "number" refers to different concepts over time. From a Lakatosian view, this is unproblematic. However, the Fregean view

would have us write different terms for these different systems. For instance, the natural numbers can refer to the integers greater than or equal to 0, or to the integers greater than 0. These should be indicated by $\text{Numbers}_{\geq 0}$ and $\text{Numbers}_{>0}$, respectively. Schlimm concludes that both views should be used to highlight different parts of mathematical practice, and therefore, he opts for a pluralistic approach.

Although Schlimm does not do this, one might relate these two views to the points of view regarding definitions listed in Sect. 3. Although the Fregean/Lakatosian views concern the relation between a term and a concept, and the traditional/heuristic views concern the nature of definitions, one can argue that the Fregean view corresponds to the traditional view, and the Lakatosian view to the heuristic view. Both the Fregean and the traditional view highlight the inferential role of definitions and concepts, whereas the Lakatosian and the heuristic view explicitly accommodate for the interference of mathematicians in the course of defining/fixing a concept for a term.

Furthermore, analogous to the case of traditional vs. heuristic, one can make similar remarks about the accuracy of the Fregean and the Lakatosian view: It is a matter of what these views try to describe. If we are looking at an idealized version of mathematics, the Fregean version might be more accurate, whereas the Lakatosian view might be more accurate for preformal mathematics or the human side of mathematics. Which view is more appropriate is dependent on the particulars of a situation.

If we do indeed want to approach conceptual change from the preformal perspective, we cannot ignore Lakatos' seminal *Proofs and Refutations* (2015). As is well-known, *Proofs and Refutations* constitutes a rational reconstruction of the research on Euler's polyhedron formula: $V - E + F = 2$ (i.e., for polyhedra, the number of vertices (V) − the number of edges (E) + the number of faces (F) = 2). The format of the book is a hypothetical discussion between a teacher and its pupils and is connected with historical events via its footnotes. The book contains a wealth of insights regarding mathematical practice. Due to space restrictions, this chapter cannot contain a review of the entire book. Nonetheless, what follows is *Proofs and Refutations*' main idea regarding conceptual change. For in-depth discussions of Lakatos' Philosophy of Mathematics, see (Koetsier 1991) and (Larvor 1998).

Proofs and Refutation's discussion starts right after the conjecture $V-E+F=2$ has been formulated, with the teacher presenting a "proof" of the theorem. However, his sense of a proof is not the standard conception of something that establishes the truth of the theorem beyond a doubt, but a "thought experiment – or 'quasi-experiment'- which suggests a decomposition of the original conjecture into sub-conjectures or lemmas" (Lakatos et al. 2015, p. 10). The students express doubt regarding this "proof" and the theorem and suggest several counterexamples, either to the theorem itself (*global* counterexamples) or to one of the lemmas in the proof (*local* counterexamples). It turns out that there is no consensus with respect to what a polyhedron actually is. The students then try to pin down what polyhedra are by presenting various definitions. It turns out that there is a dialectic between the proof and the concept of a polyhedron. What is understood by polyhedron leads to reformulations of the theorem (and its "proof"), and the steps in the proof suggest

properties that polyhedra should have. In short, improving a "proof" is a process that alters the theorem, the "proof," and the concepts involved. A concept that is the result of such a process is referred to as a *proof-generated* concept.

To get an idea of how this change occurs, one can look at the phenomena of "monster-barring" and "exception-barring." During the hypothetical discussion, some students come up with counterexamples to the polyhedra formula, i.e., a polyhedron for which either the proof fails or the theorem does not hold. One possible reaction to this counterexample is to label it a "monster," i.e., not real polyhedron. By doing this, the concept of polyhedron is revised and the validity of the proof and the theorem preserved. This is referred to as "monster-barring." A more nuanced approach is *exception-barring*, where the counterexample is not yet dismissed as a monster, but is investigated to determine the domain of validity for the theorem.

Another account of conceptual change is presented by Kitcher (1983). This description is given in a general discussion of how mathematical practices change (see Sect. 5). Kitcher argues that concepts (in particular, expressions and sentences) get meaning through so-called *initiating events*. In other words, an initiating event is the way in which a *token* of a *type term* gets appointed a referent. Due to this type/token distinction, the same concept (type term) can have multiple initiating events and the set of these events is called the *reference potential*. Ideally, this reference potential is *homogeneous*, i.e., all of its initiating events lead to the same entity.

Sometimes, however, the reference potential is *heterogeneous* and this can lead to refined expressions by adapting the referential potential so to make it homogeneous again. One of Kitcher's examples concerns Cantor's introduction of the transfinite ordinal ω. Cantor's contemporaries protested against Cantor's move from the natural numbers, a sequence that continues indefinitely, to a completion of that sequence in the form of ω. Kitcher suggests that there is a heterogeneous referential potential at work. Cantor describes ω as a number. But what do we consider numbers to be? One might for instance refer to the complex numbers and say that numbers constitute expressions of the form $a + bi$. In that sense, ω has trouble fitting the bill. However, when one considers numbers as entities on which one can perform certain arithmetical operations, then ordinal arithmetic shows that transfinite ordinals are numbers too. Therefore, this episode *stretched* the concept of number.

If one assumes that mathematical concepts are subject to change, then one can investigate how to deal with these changes. This is done by Tanswell (2018). After establishing that mathematical concepts can be inexact, he suggests that *conceptual engineering* can play a valuable role in making concepts more exact. Conceptual engineering is a branch of philosophy that looks at how concepts acquire meaning, how they are used, and how one can steer the usage of certain terms (see Cappelen and Plunkett 2020). A specific mathematical issue for which conceptual engineering can be useful concerns the concept of sets. Some argue that there exists a single set-theoretic universe, whereas others suggest that there exist many. Tanswell argues that "the best hope for a resolution is through the active deployment of the tools of conceptual engineering" (Tanswell 2018, p. 904).

In conclusion, according to some, the relation between terms and their related concepts is fixed and according to others this relation is subject to change. The next section zooms out and looks at concepts and definitions from the perspective of a mathematical community. A single mathematician might investigate a particular concept or use a definition, but what makes that other mathematicians are also interested in that concept or use that definition as well?

5 Theme III: Concepts and Definitions as Communal Notions

Mathematics is often framed as an objective and individual activity. The philosophy of mathematical practice has shown two things: There are many (inter) subjective factors in mathematics, and it is for a large part also a communal activity. In this section, we look at definitions and concepts from a *communal* perspective.

As in many other activities, there is some sense of fashion in mathematics (Wilder 1953; Thurston 1994). Therefore, one question that presents itself is as follows: What makes concepts or definitions fashionable? Corfield (2003) formulates this accurately through a hypothetical case:

> [i]f I define a *snook* to be a set with three binary, one tertiary and a couple of quaternary operations, satisfying this, that and the other equation, I may be able to demonstrate with unobjectionable logic that all finite snooks possess a certain property, and then proceed to develop snook theory right up to noetherian centralizing snook extensions. But, unless I am extraordinarily fortunate and find powerful links to other areas of mathematics, mathematicians will not think my work worth a jot. By contrast, my articles may well be in demand if I contribute to the understanding of Hopf algebras, perhaps via noetherian centralizing Hopf algebra extensions. (Corfield 2003, p. 11)

As the line "mathematicians will not think my work worth a jot" suggests, Corfield talks as if there is some general consensus to what is considered valuable or not. Whether such a consensus should exist is a topic of debate. Nonetheless, the discussion in the literature is framed as though there is such a consensus. Assuming this is indeed the case, the two questions that are discussed in this section are as follows:

1. Why do mathematicians study the concepts that they study and not others?
2. Given a concept with a variety of equivalent definitions, why would/do mathematicians prefer one definition over another?

This section starts by investigating the first question. The literature regarding this question can be split into descriptive and normative accounts. Descriptive accounts describe the processes by which concepts are introduced, by which they are (possibly) accepted, and how they "survive." Normative accounts have the implicit assumption that mathematical concepts are accepted when they are considered to be valuable. These normative accounts therefore consist of general criteria of

valuable mathematics. Finally, this section concludes with a review of the literature on the second question.

5.1 Descriptive Accounts

In discussing how mathematics develops, metaphors are often used. Hacking (2014), for instance, discusses two metaphors that explain how mathematics grows and which concepts are studied: the butterfly model and the Latin model. According to the butterfly model, mathematics develops teleologically, like a caterpillar becoming a cocoon and then turning into a butterfly. In that sense, mathematical developments are predetermined, although failures can hinder its development. By contrast, the cornerstone of the Latin model is that mathematics is not predetermined and that it evolves through contingencies. The comparison is made with how Latin evolved into various other languages.

A more concrete approach can be found in Wilder (1953), which specifically addresses the introduction and lifespan of concepts. Wilder argues that when it comes to the introduction of concepts, the communal or social aspects of mathematics are just as important as the individual aspects, if not more. He makes the case that mathematical concepts are not created out of nothing, but that they are the result of synthesizing established mathematics. "A concept doesn't just pop up full grown "like Venus from the waves," although it may seem to, to the individual mathematician who does the conceiving. Usually its elements are lying in [. . .] the *mathematical culture stream*" (Wilder 1953, p. 426).

Wilder's goal is to "inquire, above the individual level, the manner in which mathematical concepts originate, and to study those factors that encourage their formation and influence their growth" (Wilder 1953, p. 425). To this end, Wilder discusses several case studies of the introduction and evolution of concepts. From these, he identifies factors that can lead to new concepts. First of all, mathematical concepts arise from interaction with the "non-mathematical environment." He points to primitive mathematics as solutions to practical problems, in farming or taxes, but notes that contemporary mathematics is also influenced by practical, e.g., economical, problems.

Second, Wilder argues that while mathematics is partly individual (the final step in the development of a concept is by the individual), mathematics can only flourish by cooperation. In this sentence, cooperation should be read both in the literal and in a broader sense. The literal one referring to when small groups of mathematicians collaborate, the broader one indicating the efforts of previous mathematicians in generating the needed mathematical tools (e.g., "a Newton can carry on only from the level which the mathematics of his time has reached" (Wilder 1953, p. 438)). Therefore, the greatest factor for mathematical growth is what Wilder calls *conceptual contacts*.

Wilder differentiates conceptual contacts on the level of the individual from the level of the group. The first one represents meetings of mathematicians, like colloquia or international collaboration. The second refers to "diffusion of

concepts," like the fusion of two mathematical subfields (he discusses, for instance, the combination of algebra and geometry into algebraic geometry). The crucial difference is that on the group level, these developments depend on a far larger number of mathematicians.

Wilder then suggests two possible ways in which conceptual contacts can lead to new concepts. First, concepts can arise from the observation of similar structures and patterns in different branches of mathematics. He describes this as a mathematical equivalent of the observation of patterns in nature in physics. The second example of concept formation is that tools from one branch of mathematics are imported into another branch.

One can also look at the axiomatic method as a tool for concept formation. Given that a certain structure is characterized by a set of axioms, one can change one of the axioms and get another structure. Wilder mentions, for instance, how non-Euclidian geometry is obtained by substituting a nonparallel axiom for the parallel axiom. The final example of concept formation that Wilder discusses is the "well known and much abused generalization" (Wilder 1953, p. 442). He remarks that this does not only work at the individual level, but also at the group level, namely via *concept splitting*. He argues that mathematicians sometimes gradually investigate certain objects from particular points of view, each leading to different generalized versions of that concept.

In addition to these various ways in which concepts are introduced, a problem-solving oriented model for concept introduction is discussed in (Carter 2013) and (Kjeldsen and Carter 2012). Using the example of Riemann surfaces, Carter (2013) sets out to study how mathematicians handle mathematical objects, and how they prove, but ends up suggesting a model for how mathematical objects are introduced. Note, however, that where Carter writes 'objects', we can replace this with *concepts* (cf. Sect. 2). This model is crystallized and tested on the introduction of convex bodies in (Kjeldsen and Carter 2012). Despite several differences in comparison to Riemann surfaces, the introduction of convex bodies is seen as evidence for the validity of the model. The model consists of three stages.

Stage 1: The new object is defined "*with reference to already accepted objects*" (Kjeldsen and Carter 2012, p. 360). In Carter's case study on Riemann surfaces, these surfaces are used to study Abelian functions.

Stage 2: Correspondence theorems between the already accepted objects and the new object are obtained, and the already accepted objects are studied with the use of the new object and these correspondence theorems.

Stage 3: The new object is defined without reference to the already accepted objects and studied for its own sake.

The essence of this model is a motif that can be found in several other sources as well. The idea is that in order to solve a particular problem, mathematicians might go in a certain direction and that that direction turns into an established part of mathematics itself. For instance, Corfield (2003) differentiates between concepts that are *fundamental*, *convenient,* or *pointless*. The first type corresponds to concepts

that are "intrinsically worth studying" (Corfield 2003, p. 228) and the second to concepts that are "valuable as a tool" (Corfield 2003, p. 228). According to Corfield, the status of mathematical entities can change from useful tools to intrinsically worth studying. In effect, this is the same message as the model by Kjeldsen and Carter.

A general account of mathematical practices, which can also accommodate the aforementioned model, is presented in Kitcher's *The Nature of Mathematical Knowledge* (1983). Even though the main goal of this book is to show that mathematical knowledge is not a priori, this book is also well known for the introduction of the notions of *mathematical practice* and *interpractice transitions*. A mathematical practice is a five-tuple (L, M, Q, R, S), "where L is the language of the practice, M the set of metamathematical views, Q the set of accepted questions, R the set of accepted reasonings, and S the set of accepted statements" (Kitcher 1983, pp. 163–164). An interpractice transition is a transition from a practice (L, M, Q, R, S) to a practice (L′, M′, Q′, R′, S′).

For our purposes, it is interesting that, with this theory, Kitcher describes three ways in which expressions get introduced. In the first, definitions are abbreviations of other expressions and therefore serve a pragmatic purpose. This concurs with the traditional account of mathematical definitions as described in (Cellucci 2018). The second type is where a particular notion does not have a clearly defined referent and the community of mathematicians looks for a suitable interpretation of that term. This concurs with the account described by Lakatos (2015). As an example, Kitcher discusses how the term "function" evolved. The third type is Kitcher's description of conceptual change in which a heterogeneous reference potential is transformed into a homogeneous one (as described in Sect. 4).

In general, Kitcher presents five patterns of how practices change, namely question-answering, question-generating, generalization, rigorization, and systematization. The motif that some mathematical concepts that were introduced as a means to study another concept become the subject of investigation themselves arises via the patterns of question-answering and question-generating. Concretely, mathematical concepts are sometimes introduced by question-answering. However, these mathematical concepts can lead to questions about those concepts, i.e., a case of question-generating.

These patterns of change are also reviewed by Schlimm (2012). He uses them for the construction of five patterns of *conceptual* change: "Clarifications of informal concepts, systematizations of concepts and results, investigations of sharp concepts (defined by axiom systems), and generalizations and abstractions" (Schlimm 2012, p. 138). He suggests that these can lead to new or modified mathematical concepts. However, Schlimm only mentions these patterns and does not investigate them any further.

Next to looking at how certain concepts can become topics of study, one can also inquire into what Wilder (1953) calls the "life span of a concept." He argues that usually, concepts become fashionable and are studied intensely until they are no longer fashionable. When that happens, the concept's life span has ended. However, concepts can become very old or even immortal when they are connected to other mathematical concepts. Unfortunately, Wilder cannot give examples of concepts that

have died out completely. He remarks that mathematics has a tendency to reorganize itself, making various distinct parts of mathematics coherent. In that way, concepts never really die out but survive by being absorbed by a general theory.

5.2 Normative Accounts

Several authors tacitly assume that valuable mathematics becomes part of the shared mathematical theories and mathematics with little to no value does not. Muntersbjorn (2003) discusses this relation explicitly. She argues that the history of mathematics is sometimes wrongfully portrayed as teleological: Earlier mathematics is developed to facilitate later mathematics. Nowadays, mathematicians might value historical mathematical theories because of the possibilities they provide for our contemporary mathematics. However, that need not be why the theory was appreciated originally. She writes:

> Mathematics is a goal-oriented activity. In general, mathematicians strive to solve problems as quickly, accurately, and generally as possible. But the immediate goals of early individuals cannot be identified solely with the particular accomplishments of later individuals. [. . .] An important measure of mathematical success is the extent to which a particular result enables subsequent results. Good mathematics is fruitful. Yet, mathematical results must have immediate value for their community of origin before they can become candidates for further elaboration, as results without immediate value do not get passed down to the next generation. (Muntersbjorn 2003, p. 163)

Therefore, Muntersbjorn claims that there is a connection between mathematical concepts being accepted and cultivated, on the one hand, and being deemed valuable, on the other. Regarding these values, Muntersbjorn suggests "that the value of a mathematical innovation depends on its provenance and potential. Good mathematics originates from the identification of tacit insights responsible for prior success and generates further success" (Muntersbjorn 2003, p. 175). In addition to provenance and potential, she also discusses the importance of psychological factors such as brevity and clarity.

The quality or value of concepts is also discussed by Carballo (2020). His main question is as follows: In virtue of, what is a concept, better or worse, epistemically? Carballo argues that several claims have been made that some concepts are better because they are more "natural," "sparse," "joint-carving," etc. He refers to these terms as *elite* properties. Carballo first puts forward the hypothesis that concepts are epistemically better if and because they are more elite than others. Then Carballo tries to argue against that hypothesis. He presents several arguments. For instance, good concepts figure in good explanations. However, good explanations do not necessarily need elite concepts. Therefore, eliteness is not necessary for good concepts. Whether Carballo makes a convincing case is beyond the scope of this chapter, but the fact is that when it comes to evaluating concepts (or definitions), mathematicians often refer to values like naturalness or fruitfulness. We will come back to this in Sect. 6.

One can also look at the success of mathematical developments in general. Corfield (2001, 2003), for instance, argues that mathematicians often have to present the value of their work. He presents five criteria for valuable mathematical developments:

1. when a development allows new calculations to be performed in an existing problem domain, possibly leading to the solution of old conjectures;
2. when a development forges a connection between already existing domains, allowing the transfer of results and techniques between them;
3. when a development provides a new way of organising results within existing domains, leading perhaps to a clarification or even a redrafting of domain boundaries;
4. when a development opens up the prospect of new, conceptually motivated domains;
5. when a development reasonably directly leads to successful applications outside of mathematics. (Corfield 2001, pp. 508–509)

Developments that score high on all criteria are considered to be uncontroversially valuable. When developments do not score high on all criteria, the value depends on a tacit weighing of the criteria.

As these criteria are formulated quite generally, they do not only apply to concepts, but also to definitions. Some definitions can be valuable because they provide "a new way of organising results within existing domains" (see point 3) or because they forge "a connection between already existing domains" (see point 2). However, there is also literature that addresses the value of definitions directly.

5.3 Why Do Mathematicians Use Certain Definitions and Not Others?

An approach that addresses the value of definitions can be found in (Werndl 2009). Her main question is: "in what ways are definitions in mathematics justified, and are these kinds of justification reasonable?" (Werndl 2009, p. 313). Werndl argues that it is important to justify definitions, since unjustified ones are less meaningful to "us." Note that Werndl's use of the word "us" suggests some form of consensus on what are meaningful definitions. Therefore, she concludes, justified definitions are the ones we should focus on.

The first type of justification she identifies is the Lakatosian *proof-generated definition*. Note, however, that in *Proofs and Refutations*, proof-generated *definitions* are seldom discussed; Lakatos mainly discusses proof-generated *concepts*. Nonetheless, Werndl suggests that "[Lakatos'] main idea is the notion of a *proof-generated definition*. Here his main example is definitions of polyhedron which are justified because they are needed to make the proof of Eulerian conjecture work" (Werndl 2009, p. 315). Extrapolating the meaning of proof-generated concepts to proof-generated definitions, one might argue that the latter are definitions that are the result of improving a proof. Werndl phrases this as "a definition which is needed in order to prove a specific conjecture regarded as valuable" (Werndl 2009, p. 315). Note that in suggesting that definitions can be justified by being proof-generated, the

term "definition" should be interpreted as *concept*. A part of proof-generated definitions is that they capture the right domain of validity for the theorem. This then involves not the *definitions* themselves, but the *concepts* they correspond to.

Next to the justification of definitions being proof-generated, Werndl identifies three other types of justifications of definitions:

- Natural-world justified definitions: definitions that "*capture a preformal idea regarded as valuable for describing or understanding the natural world*" (Werndl 2009, p. 320)
- Condition-justified definitions: "*a definition … justified by the fact that it is equivalent in an allegedly natural way to a previously specified condition which is regarded as mathematically valuable*" (Werndl 2009, p. 326)
- Redundancy-justified definitions: a definition that "*eliminates at least one redundant condition in an already accepted definition*" (Werndl 2009, p. 330)

In these cases, the term "definition" does refer to *definitions*. Natural-world justifications are about what *captures* a preformal idea, condition-justified definitions show that a certain expression captures a relevant condition as well, and redundancy-justified definitions are more economical than others.

Furthermore, one can examine how certain definitions developed over time. As mentioned, Raman-Sundström (2015) does this by looking at "the origin and development of open-cover and sequential compactness" and "how and why open-cover compactness came to be favoured" (Raman-Sundström 2015, p. 619). She shows how in general topology, open-cover and sequential compactness are not equivalent and that the open-cover version was preferred because it is "more general and applicable" (Raman-Sundström 2015, p. 629).

In the final comments, she remarks that "the story of how open-cover compactness came to be seen as the right one is a story of developing mathematics without always knowing where it was going, how important terms should be defined and how widely they might be applied" (Raman-Sundström 2015, p. 633). Even though the mathematicians involved might not always have known where the path would lead them, Raman-Sundström also shows that many choices were based on values. This becomes clear from the following excerpts:

- "[Frechet] preferred definitions that had an intuitive feel rather than analytic power" (Raman-Sundström 2015, p. 625)
- "Alexandroff claimed the accumulation point characterization was most important initially, due to the dominance of the Bolzano–Weierstrass property, but after some years it became clear that the open-cover property was more fruitful" (Raman-Sundström 2015, p. 625)
- "some mathematicians find nets more intuitively appealing and useful, while others prefer filters" (Raman-Sundström 2015, p. 631).

The next section discusses several values regarding definitions and concepts.

6 Theme IV: Values Regarding Mathematical Definitions and Concepts

As the above section shows, values play an important role when it comes to concepts and definitions. Not only is mathematics often evaluated on the basis of values (see Sect. 5.2), mathematical developments are also often steered by these values (see Sect. 5.3). Usually, these values are referred to in an imprecise and informal way. As a response, there are several efforts to make these notions more precise. In this section, philosophical accounts of three values are discussed: naturalness, fruitfulness, and explanatory value.

6.1 Naturalness

Mathematicians often describe constructions and concepts as "natural." Although there are methodological difficulties involved in studying an informal concept like "natural" (Mauro and Venturi 2015), several authors have reflected on this term. For instance, Corfield (2003) briefly differentiates between three types of naturalness. The first interpretation sees natural as the opposite of artificial. Natural concepts are those that we can encounter "in nature." This, obviously, does not refer to the same nature in which one encounters plants and birds, but to "reasonably well frequented regions of mathematics" (Corfield 2003, p. 224). In the second interpretation, naturalness is linked to inevitability. Natural concepts are those concepts that mathematicians will discover at some point. Formulated more strongly, natural concepts "will necessarily appear and that, by virtue of their nature, they rather than the user will determine their use" (Corfield 2003, p. 226). If mathematicians from various backgrounds discover the same concept, then this indicates that the concept might be a natural one. Lastly, Corfield discusses a narrow interpretation of naturalness, based on origins of category theory. In this interpretation, naturalness constitutes the absence of arbitrary choices. For instance, the proof that every vector space is isomorphic with its double dual is considered natural as it requires no choice of basis. Where Corfield discusses naturalness of concepts, constructions, proofs, and a variety of mathematical phenomena, Tappenden (2008a) zooms in on concepts and definitions. He describes naturalness in terms of "carving at the conceptual joints." Then he looks at two examples, the Legendre symbol and prime numbers. Regarding the first, he asks (1) whether this concept is natural and (2) how we can establish its naturalness. At first sight, the Legendre symbol seems to be an artificial concept due to the case distinction in the definition (The Legendre symbol is defined by: for an odd prime p, an integer a, $\left(\frac{a}{p}\right) = 1$, if a is a quadratic residue modulo p; $\left(\frac{a}{p}\right) = -1$, if a is a nonquadratic residue modulo p; and $\left(\frac{a}{p}\right) = 0$ if $a \equiv 0 \pmod{p}$.). However, it also appears to unify the theory of quadratic reciprocity. Tappenden remarks this and concludes that there are two possible perspectives on the symbol: Either it is a useful notion which helps to streamline the theory, in which case it is mathematically natural,

or it is only useful because it is a gerrymander in a particular context and not generally useful, and therefore, not natural. Tappenden argues for the first approach by showing that the Legendre symbol is useful in various different mathematical contexts and that it proves to be a key notion in various generalizations. He therefore concludes, regarding questions (1) and (2) that "[i]t is a mathematical question whether the Legendre symbol carves mathematical reality at the joints and the verdict is unequivocally yes" (Tappenden 2008a, p. 264).

Tappenden also considers the carving at the conceptual joints in the case of prime numbers. He provides two definitions:

1. A natural number P is prime if and only if the only divisors of P are *1* and *P*.
2. A natural number P is prime if and only if for every pair of natural numbers a, b we have that if P divides ab, then P divides a or P divides b.

Although these definitions are equivalent in the context of natural numbers, the definition that is taught to high school students is the first. In contexts like algebraic number theory, however, these definitions are no longer equivalent. In order to generalize the notion of primeness, mathematicians have to choose between these definitions. To make this decision, Tappenden argues, mathematicians look at the original theorems involving prime numbers to see which property was actually doing the heavy lifting so that these theorems can be generalized. It turns out that in the general context, the high school definition is referred to as *irreducibility* whereas the other is referred to as *primeness*. The second definition therefore carves at the conceptual joints of primeness.

6.2 Fruitfulness

Fruitfulness is seen by Tappenden (2012) as a bridge between the foundational works of Frege and the study of mathematical practice. The main connection is Frege's view that "logical reasoning needs 'fruitful concepts' to extend knowledge, and that identifying and studying the fine structure of such concepts can produce further discoveries" (2012, p. 205). Several authors have tried to make sense of Frege's usage of the term fruitful for definitions (Shieh 2008; Tappenden 1995, 2012; Horty 2007). The consensus seems to be that some definitions are merely collections of unordered characteristics, whereas others display a logical structure That, when analyzed, leads to new knowledge. In that sense, fruitful definitions are those that enable the extension of knowledge. Horty (2007), on the other hand, takes this notion and contrasts it with other parts of Frege's theory of concepts. He concludes that there is a friction between the conception of definitions as abbreviations (cf. Sect. 3) and definitions as being fruitful. If definitions should not increase the inferential power of a logical system, how can they lead to new knowledge? Horty then assesses Frege's work to explain this seeming contradiction, the details of which are beyond the scope of this text.

After discussing Dedekind's remarks on fruitfulness, which are similar to Frege's, Tappenden (2012) asks: "how can Frege/Dedekind's recognition of fruitfulness as a practical basis for choice of concepts and definitions in mathematics helpfully guide us?" (2012, p. 211). He hopes to show that by looking at fruitfulness, we can better understand the reliance of mathematicians on "beauty." More generally, Tappenden argues that many judgments like "elegance" or "simplicity" have a guiding role in science, even though it is not clear why these notions would lead to truth. Therefore, he concludes, we should look at those notions in detail. In Tappenden (2012), he makes a start by exploring a connection between beauty and fruitfulness. He argues that seeing the way one result might lead to other, can lead to an aesthetic reaction.

Fruitfulness is also discussed by Yap (2011). She first tries to grasp the notion by looking at remarks by Gauss and provides a mathematical interpretation of those remarks. In this interpretation, mathematical calculi are fruitful if they can be integrated in existing methods, if they help to split mathematical problems into subproblems, and if they help to capture the core of the issues we frequently encounter. Note, however, that a "calculus" is not the same as a "concept," in general. However, one of the cases that Yap discusses is the Legendre symbol which is also discussed in Tappenden (2008a, b). Therefore, Yap's article on the fruitfulness of calculi is also discussed here.

She then compares the Legendre symbol with Gauss' congruence notation, i.e., $a \equiv b \pmod{n}$. She argues that Gauss' congruence notation and not the Legendre symbol was useful for *proving* the quadratic reciprocity theorem. Yap presents three arguments for the usefulness of Gauss' congruence notation: It rather straightforwardly leads to partitioning the integers in equivalence classes, equivalence behaves much like equality, and this calculus enabled the induction strategy that is essential in Gauss' first proof of the theorem.

Yap argues that the Legendre symbol is not as fruitful as the congruence notation, because it is too specific. She concludes that the congruence notation has the right balance between generality and specificity. Nonetheless, the Legendre symbol has proved to be useful, but that usefulness is "tied to the truth of the reciprocity theorem itself, whereas the usefulness of congruences, being more general, is wider" (Yap 2011, p. 414).

6.3 Explanatoriness

It has been established that many mathematicians refer to proofs as being explanatory. Consequently, there have been many efforts to describe what mathematical explanation actually is (see D'Alessandro 2019). Another question regarding mathematical explanation is about which mathematical techniques are (or can be) explanatory or not. Lange (2009), for instance, argues that mathematical induction, in general, is not explanatory. Lehet (2019) disagrees and looks at induction in mathematical definitions to argue that it can be explanatory in some cases.

To do this, Lehet first expands the theory of mathematical explanation to cover explanatory definitions as well. "A mathematical definition is explanatory if it makes

the mathematical concept being defined more accessible—i.e., it explains some feature or property of the relevant concept" (Lehet 2019, p. 6). She gives two examples of explanatory definitions. The first concerns the derivative. She focuses on which definition might be best suitable for an introductory calculus course. She argues that a definition of the derivative, as a limit of secants and tangents, is more explanatory than one in which the algebraic manipulations are highlighted (e.g., $\frac{d}{dx}x^n = nx^{n-1}$). For those only interested in calculating the derivatives, the algebraic example is preferable. However, for a more profound understanding, the limit example is preferable, and as the limit definition makes the "deeper meaning accessible" (Lehet 2019, p. 8), it is explanatory.

The second example concerns CW-complexes. The details are beyond the scope of this text. The crux is that CW-complexes are larger spaces, constructed out of smaller spaces. By doing this, mathematicians can reduce complex properties of these larger spaces into a number of simpler properties of smaller spaces. In effect, these larger spaces become accessible by reducing them to a number of accessible smaller spaces.

Although Lehet (2019) was the first to explicitly discuss explanatory definitions, the aforementioned article by Raman-Sundström (2015) in a sense already shows how explanatoriness is an important factor for definitions. Given the vast literature on mathematical explanation in general, there are many opportunities for further investigating explanatory definitions.

7 Conclusion

Definitions (and concepts) in mathematical practice is not a standard topic of investigation in the philosophy of mathematical practice. Usually, they are discussed in light of others matters; for example, Kitcher (1983) discusses conceptual change in his description of mathematical practices. In the above, the literature on definitions (and concepts) is structured using five themes. Whereas definitions and concepts are intricately related, the first theme focuses on definitions: What is the nature/role of definitions? As one important function of definitions is specifying the meaning of a term, the relationship between terms and concepts constitutes theme two. From a broader perspective, one can look at how definitions and concepts are accepted and studied by mathematical communities, which is theme three. Within this theme, one can further differentiate between descriptive and normative accounts of how concepts enter the shared mathematical scope and literature on why certain definitions and not others are used. Theme four is about various values that are attributed to concepts and definitions. This is summarized in Fig. 1.

These themes are not disjoint. For instance, the work by Tappenden (2008a) shows why the mathematical community might choose to work with a particular definition (cf. theme III) as well as the role of the naturalness considerations in this decision (cf. theme IV). Moreover, some types of conceptual change (cf. theme II)

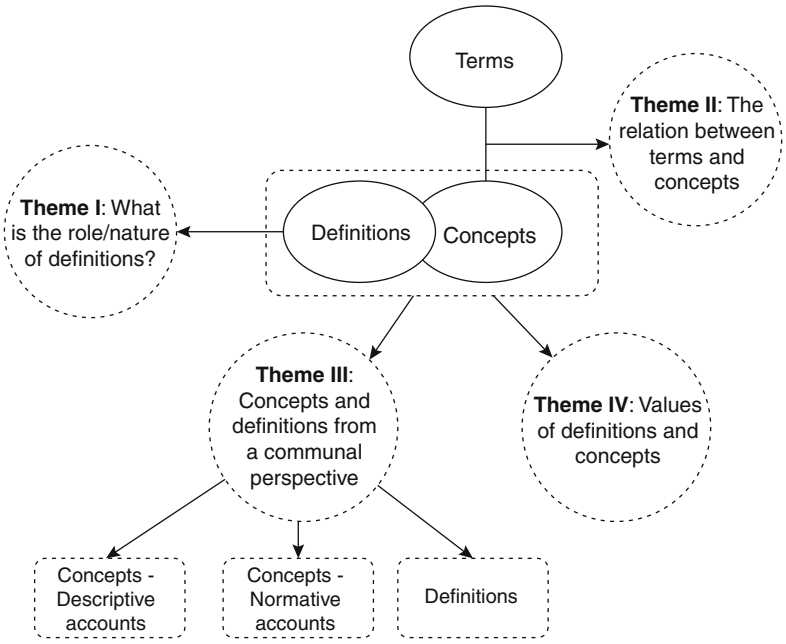

Fig. 1 The four themes and their relations

can also be considered cases of certain concepts becoming fashionable and others falling out of fashion (cf. theme III).

The themes represent different paths that lead to the discussion of definitions and concepts in mathematical practice. However, these paths are connected. For instance, beneficial properties of definitions (cf. theme IV) are dependent on the expectations and aims of definitions (cf. theme I). Different values (cf. theme IV) can guide the process of choosing which concept to relate to a term (cf. theme II). Definitions can become fashionable because they capture a relevant concept in a natural way (cf. themes II, III, and IV). Studying the relations between the different themes is therefore a promising avenue for future research.

Mathematics and the Method of Abstraction

Kit Fine

Abstract

I provide a brief history and some philosophical reflections on the development of the method of abstraction in mathematics during the late nineteenth and early twentieth century.

Keywords

Abstraction · Frege · von Neumann · Cantor · Locke · Berkeley · Russell · Number

It is a familiar thought that mathematics derives from abstraction. We observe three rocks, three stars, three French hens and from these respective observations we are able to derive the concept of the number 3; or we observe a line in the sand and from this observed line, thick and wiggly as it may be, we are able to derive the concept of a line, perfectly indivisible in extent, absolutely straight, and extending infinitely in either direction; or we observe a car in motion, the rising temperature of the air, or the increasing volume of the water in the tub and from these sundry observations we are able to derive the concept of the rate of change of one quantity with respect to another.

Abstraction may be a familiar idea but it is also vague. What exactly is abstraction? *From* what do we abstract? *To* what do we abstract? And *how* do we get from the one to the other?

This chapter is based upon an address I gave to a general audience in 2013, under the auspices of the Humboldt Foundation.

These are questions which have been discussed since the beginning of mathematics and philosophy. But what I want to consider is the discussion of the questions in a particular period and by a particular group of people. The period was the end of the nineteenth century and the beginning of the twentieth century. And the people in question were mathematicians who had a strong interest in foundational issues. They were not only concerned to *do* mathematics but also to put the subject on a firm foundation.

The period was, I believe, a time when discussion of abstraction came to fruition. And this, certainly, was no accident. For this was a time when many of the most significant advances in mathematics depended upon extending its ontology. Mathematicians could no longer be content with the familiar numbers of arithmetic or the familiar points of Euclidean geometry; they also had to traffic in complex numbers, points at infinity, transfinite numbers, and the like. The question therefore arose as to what might justify these extensions of the familiar ontology; and to many mathematicians it seemed that the answer lay in the method of abstraction. These new objects were to be introduced and legitimated, if at all, on the basis of abstraction.

When one examines the mathematical writings of this period, then there are, I think, three main conceptions of abstraction that emerge. I will call them abstraction via *extension*, via *subtraction*, and via *representation*. Each of these three conceptions is associated with particular authors – extensional abstraction with Frege and Russell, subtractive abstraction with Dedekind and Cantor, and representational abstraction with Zermelo and von Neumann. And so what I would like to do is to discuss each conception in turn, more or less as it was developed by the respective authors.

In each case, I shall focus on the case of natural numbers – the numbers 0, 1, 2, . . . and the question of how they are to be obtained by abstraction. But it is important to bear in mind that the case of numbers is merely illustrative. The method of abstraction is meant to have more general application – to the rational numbers, for example, or to the reals of analysis, or to directions in geometry, or to free groups in algebra, and so on and so forth.

In each case, I shall emphasize the historical and philosophical milieu in which the investigation into abstraction took place. For it is my view that this investigation did not take place within some isolated mathematical bubble but was heavily informed by previous philosophical discussion of the issues, dating all the way back to Euclid. Sometimes this influence was conscious – as in the case of Frege and Russell and Cantor – but, even when it was not conscious, there is no doubt of its presence.

I begin with Frege and his account of abstraction as a form of extension. Gottlob Frege was a German mathematician, who was born in 1848 and died in 1925 and who spent most of his working life in Jena. He is best known for his work in logic, the philosophy of mathematics, and the philosophy of language and he is commonly regarded as the founder of analytic philosophy.

Although Frege seems to have received very little formal training in philosophy, there is no doubt that he was very well read in the subject. His work is replete with references to philosophers, both past and present; and he himself is credited with having said “Every good mathematician is at least half a philosopher, and every good

philosopher is at least half a mathematician." (If only more philosophers and more mathematicians would heed his words!)

His principal contribution to the philosophy of mathematics may well be regarded as a response to Kant. Kant had thought that arithmetical truths were synthetic apriori. They were a priori in that they could be known independently of experience – no experiments are required, for example, in order to know that $2 + 2 = 4$; and they were synthetic in that their truth could not, in general, be revealed through analysis alone. Whereas the truth of "every bachelor is unmarried" could be made evident through the analysis of the subject term "bachelor" as "unmarried man," no such analysis would reveal the truth of $2 + 2 = 4$. Frege, by contrast, held that all that arithmetical truths were analytic, that, just as in the bachelor case, a proper analysis of "2" and "+" and "4" would make evident the truth of $2 + 2 = 4$; and a large part of his detailed work in the philosophy of mathematics was devoted to showing how this was so.

To do this, Frege had to give an analysis of "2" and of other number concepts; and it is here that he appeals to the idea of extensional abstraction. Consider all pairs of objects: the pair of cities, Hamburg and Berlin; the pair of celestial bodies, the sun and the moon; or the pair of politicians, Trump and Merkel. Despite their vast differences, they all have something in common – duplicity or being double. A natural thought is that one might then take this common element of duplicity to be the number 2.

But what does one mean by saying that all these pairs have duplicity in common? What is this duplicity and what is it for a pair to have it? Frege's answer is beautifully simple. Just as we can collect objects into pairs, so we can collect all pairs. Thus we may take duplicity to be the collection of all pairs – or perhaps more simply still, it is the set of all sets with two members. But how can I say that a set has two members without presupposing the number 2? Simply by saying that there is a member x and a distinct member y which are such that very member of the set is either identical to x or identical to y. In this way, we can provide a purely logical definition of the number 2 and any more substantive conception of number simply disappears in a puff of logical smoke.

Moreover, the account generalizes. For given any two collections we can say that they are "equinumerous" if they can be paired one to one. The collection of boys and the collection of girls at a party, for example, will be equinumerous (in this purely logical sense) if they can be paired off, with each boy going with one girl and each girl with one boy. Given a collection of objects, we can then say that its number is the collection of all equinumerous collections; and a number, in general, will be the number of some collection.

Frege's account of number did not appear out of the blue. It owed a great deal to the discussion of the role of ideal elements in mathematics earlier in the century. Frege himself credits one critical aspect of his account to Hume. In his Treatise (Part 3 of Book 1), Hume had written:

> When two numbers are so combined, as that the one has always a unit answering to every unit of the other, we pronounce them equal.

And it was this "standard of equality," as Hume called it, that provided Frege with his general account of number. But Frege went one step further. For he did not simply adopt one-one pairing as a "standard of equality" but took numbers themselves to be the embodiment of that standard, with each number being a totality of collections that conformed to the standard.

I turn to Cantor and Dedekind and what I have called their subtractive account of abstraction. I shall focus on Cantor, although Dedekind held very similar views.

Cantor was a German mathematician, who lived from 1845 to 1918 and who spent most of his working career in Halle. He is best known for founding set theory and developing the theory of transfinite number. David Hilbert, in a rare accolade, called his work in this area "the finest product of mathematical genius and one of the supreme achievements of purely intellectual human activity."

I do not know what formal training Cantor received in philosophy but there is no doubt that he took his work on the transfinite to require philosophical defense. He was especially concerned with investigating previous philosophical work on the infinite to see if it provided any good arguments for or against his conception of actual infinity. Indeed, at one point in his career, when he was especially depressed about the reception of his mathematical work, he asked if he could lecture on philosophy instead! He was also an accomplished violinist and spent a large amount of time studying Elizabethan literature in the attempt to show that Francis Bacon wrote the plays attributed to Shakespeare. Perhaps we should say, not that he was half mathematician and half philosopher, but quarter mathematician, quarter philosopher, quarter musician, and quarter literary critic.

I cannot deal with his theory of transfinite number here. But I do want to look at one aspect of that theory which is invariably overlooked in contemporary expositions of his work but which bears directly on the question of abstraction. Cantor wanted to extend numbers from the finite to the infinite. He did not simply want to use the natural numbers to count finite collections; he also wanted to count the natural numbers themselves. And not just the natural numbers but all sets of natural numbers. And all sets of such sets. And so on.

To this end, he required a uniform account of number, one which would apply equally well to the finite natural numbers and to the transfinite cardinals, by which infinite collections of objects might also be counted. Take the number 2, as an example. What is it? Like Frege, Cantor thought that the number 2 could be obtained by abstraction from all pairs. But his conception of abstraction was quite different. Instead of collecting all pairs of objects together to form a single object, the number 2, Cantor focused on a particular pair – it does not matter which, say the pair consisting of Anthony and Cleopatra – and then stripped the two objects of all their defining features – the color of their hair, the softness of their skin, even their humanity – until we were left with two objects which differed merely in being distinct. The resulting pair of objects was then taken to be the number 2. Thus the number 2 was itself a pair of objects, but no ordinary pair, but a pair of objects that had been stripped of all individuality beyond their mere numerical difference. A similar account would then apply to all finite collections of objects or all collections whatever, whether finite or infinite.

Cantor likened his account to Euclid's well-known account of number as a multiplicity of units, where he took the units to be what is left of the concrete individuals once they have been stripped of their individuality. But one might also compare Cantor's account of number to Locke's account of abstract ideas. One obtains an abstract idea of a triangle by stripping away the particular idea of a triangle of all those features – such as being right angled or obtuse or acute – that might distinguish it from one kind of triangle as opposed to another. Clearly, the process by which Cantor's units are obtained is similar, though in this case the stripping away is much more drastic, since only the mere identity of the particular is left. A further difference is that a unit is not left, in a solitary denuded state, out in the cold; it has similar denuded companions and these may combine with one another to form sets or other more complex structures. One might say that Cantor's conception of abstraction is the same as Locke's but with a mathematical twist, making it more rigorous and more suited to the needs of mathematics.

Bishop Berkeley subjected to Locke's account of abstract ideas to scathing criticism; and Frege, in his turn, subjected Cantor's account of numbers as sets of units to what was possibly even more scathing criticism. It seems that, in either case, we can form no intelligible conception of what an abstract idea of a triangle or of what a unit might be; and even Locke, in what appears to be an unguarded moment, admits that the abstract idea of a triangle "must be neither equilateral, nor equicrural, nor scalenon; but none and all of these at once." A strange thing, indeed!

My view is that the criticisms of Berkeley and Frege can be met, that the Cantorian view can be put on a firm mathematical foundation, and that it thereby offers a much more satisfactory and fruitful account of number than the Fregean account. I cannot argue this here but let me note that the Cantorian view is much more *natural* than the Fregean view. If we want the number two to be what is *common* to all pairs, then it cannot sensibly be regarded as the set of all pairs but is much more naturally regarded as the template, so to speak, from which all pairs might then be derived. But the set of two units provides such a template. Substitute Anthony and Cleopatra, or any other two objects, for the units and one thereby obtains the pair of those objects; the particular pairs are, in this way, derived from the generic set that is common to all pairs.

The Frege-Russell account of number, by contrast, is highly artificial – instead of telling us what different pairs have in *common* it simply piles them one on top of the other within an over-arching set. Imagine, upon being asked what all cocktails have in common, one was simply given more cocktails! Moreover, in standard axiomatizations of set theory, the account is inconsistent. To put it crudely, the totality of *all* pairs, including pairs of objects that include this totality itself, is too large to constitute a well-defined set and, in conjunction with other plausible assumptions, the assumption of its existence will lead to contradiction.

I turn finally to Zermelo and von Neumann and their development of the representational account of abstraction. I shall focus on von Neumann rather than Zermelo since, in his hands, the representational account of number received its most developed form.

John von Neumann lived from 1903 to 1957. He was an infant prodigy able to perform complex mathematical calculations at lightning speed. He made significant

contributions to a wide number of different fields – including game theory, quantum mechanics, the theory of computing, and the foundations of mathematics – and was perhaps the most versatile mathematician who ever lived.

My concern, as before, is with his account of number and with its significance for the concept of abstraction. We have already encountered two accounts of number. According to the first, Frege's, the number 2 is the set of all pairs. According to the second, Cantor's, the number 2 is a generic pair, the pair of two units. Von Neumann's account is different still. Like Cantor, he takes the number 2 to be itself a pair. But he does not take it to be a pair of units but a pair of ordinary objects. But which objects might these be? Surely, we cannot take the number 2 to be the pair Anthony and Cleopatra. For Anthony and Cleopatra, intense as their love may have been, are only one pair among many; and why choose Anthony and Cleopatra, rather than Trump and Merkel or the sun and the moon – two other remarkable pairs?

Von Neumann realized that there was a very natural choice for the pair. For we might take the number 2 to be the set of its predecessors. 2 has two predecessors, 1 and 0; and so the number 2 will be the set whose members are 1 and 0; a two-membered set. But what of 1 and 0? A similar account may be given. 1 will be the set of its predecessors. But it has only one predecessor, viz. 0, and so 1 will be the set whose sole member is 0. 0 itself has no predecessors and so it will be the null set, the set with no members. Thus 2 will turn out to be the set whose members are 1, that is, the set whose sole member is the null set, and 0, that is, the null set. And similarly for all other natural numbers.

One nice feature of von Neumann's account is that it readily extends to the transfinite. According to Cantor, there should be a transfinite ordinal ω that occurs after all the natural numbers. But this can now be taken to be the set of natural numbers. Likewise ω + 1, the next ordinal after ω, can be taken to be the set whose members consist of the natural numbers and the set of all natural numbers. And so on, through ever higher levels of infinity.

Another nice feature is that it does not lead to paradox and conforms to a well-founded conception of sets. If I take a number, it will be the set of preceding numbers; each of those, in its turn, will be the set of preceding numbers; and so on. Eventually, the whole construction will bottom out in the empty set, that is, the number 0.

There is little doubt that von Neumann saw his account of number as an alternative to the Frege-Russell view and perhaps to the Cantorian view as well. He says of his account "What we really wish to do is to take as the basis of our considerations the proposition: 'Every ordinal is the type of the set of all ordinals that precede it.' But in order to avoid the vague notion 'type,' we express it in the form: 'Every ordinal is the set of the ordinals that precede it'" (von Neumann 1923, p. 347 of the English translation). But what is this "type" that is said to be vague? Von Neumann could only have had two models in mind: the Frege-Russell type which is obtained by extensional abstraction; or the Cantorian type which is obtained by subtractive abstraction. But he would have regarded both as unsatisfactory – the first because it leads to inconsistency and the second because it seems hopeless obscure.

In the face of these difficulties, he made the bold move of replacing the type with a particular instance of that type, the set of preceding ordinals.

Those familiar with the history of philosophy will recognize that he makes the same move as Berkeley made in response to Locke. As I mentioned, Berkeley criticized Locke's theory of abstract ideas as incoherent, but he had a positive view of his own, which Hume described as "one of the . . . most valuable discoveries that has been made . . . in the Republic of Letters." His view was that the role played by Locke's abstract idea should instead be played by a particular idea that served to represent all similar ideas or, to state the view in less psychological terms, the type was to be replaced with a particular instance of the type but used in a generic way to represent all other instances of the type. Thus just as Cantor is Locke with a mathematical twist, so von Neumann is Berkeley with a mathematical twist. For von Neumann did not simply choose any particular instance to represent the type but a very particular instance, one that was especially well suited to meet the mathematical demands placed upon an adequate theory of number within the context of set theory.

I do not want to say that Cantor or Zermelo or von Neumann explicitly had Locke or Berkeley in mind. Indeed, I doubt that they did. But I find it hard to believe that, as well educated individuals, they were not to some extent familiar, either directly or indirectly, with the empiricist debate over abstract ideas and were not to some extent influenced by it.

Let me conclude with two general points. The first is that the work of these mathematicians was not only relevant to the foundations of mathematics but has become assimilated into general mathematical practice. Any mathematics undergraduate is likely to encounter some form of these different methods of abstraction in his or her study. An example is arithmetic modulo 2 (or, more generally, modulo n). Consider again the natural numbers and suppose we ignore the difference between all of the even numbers, on the one hand, and all of the odd numbers on the other hand. Then abstraction gives us two numbers, so to speak, the Odd and the Even. The numbers can then be added and multiplied. Odd plus Even will be Odd, for example, Odd plus Odd will be Even, while Odd times Even will be Even. But mathematically speaking, what are these numbers, the Odd and the Even? Here the method of extensional abstraction may be used. For we can identify the Even with the set of all even numbers and the Odd with the set of all odd numbers. Moreover, this procedure can be generalized to cover many other cases in which we are given some elements, such as the numbers, some operations on these elements, such as addition and multiplication, and wish to identify certain of these elements, just as we have identified all odd numbers and all even numbers (another nice example is Conway's theory of surreal numbers, in which each surreal number is identified with a set of surreal "forms").

The methods of extensional and representational abstraction have been thoroughly absorbed into the mathematical literature. But my own view is that the potential of subtractive abstraction has not been fully realized and that there is a great deal more that could be done, both in making the idea mathematically precise and in applying it across a wide range of different fields.

The second point is that this work on abstraction would not have been possible – or so readily possible – in the absence of an intellectual milieu in which there was a free interplay between mathematical and philosophical ideas and that such a milieu would not itself have been possible if the mathematicians had not themselves had some kind of philosophical background or had been receptive to philosophical ideas. As we look back, we can see how beneficial it was for them to be working within such a milieu; and, as we look forward, we should be aware, even in this age of increased specialization, of how important it is that the interplay between mathematical and philosophical ideas be sustained.

Abstract

This chapter examines the pioneering work of Gottfried Wilhelm Leibniz (1646–1716) on various number systems, in particular binary, which he independently invented in the mid-to-late 1670s, and hexadecimal, which he invented in 1679. The chapter begins with the oft-debated question of who may have influenced Leibniz's invention of binary, though as none of the proposed candidates is plausible, I suggest a different hypothesis that Leibniz initially developed binary notation as a tool to assist his investigations in mathematical problems that were exercising him at the time, namely those concerning the divisibility of composite numbers, primality, and perfect numbers. The chapter then explores Leibniz's development of binary, his little-known work on binary fractions and expansions, his use of binary as a symbol for creation in his philosophical-theology, and his response to the suggestion that there was a correlation between binary numeration and the hexagrams of the ancient Chinese divinatory text, the Yijing. The chapter

1 Introduction

Although the German polymath Gottfried Wilhelm Leibniz (1646–1716) made original contributions to a wide range of disciplines, such as law, philosophy, politics, languages, and many areas of science, his fame and renown have always rested principally on his pioneering mathematical work, in particular his independent invention of the calculus in 1675. Another of his enduring mathematical contributions was his invention of the binary number system, the basis for today's world of digital computing and communications. In this system, which uses only two digits – 0 and 1 – every position starting from the right represents a successive power of 2, such that the rightmost place is the 2^0 (or 1's) column, the next-rightmost place the 2^1 (or 2's column), and so on. While Leibniz had a particular fascination with binary, his work on nondecimal number systems covered all the bases, or at least bases 2–16. Particularly notable is his invention of base 16, or "hexadecimal" in modern parlance (Leibniz called it "sedecimal" and "sedenary"), another number system used in modern computing.

128's	64's	32's	16's	8's	4's	2's	1's
1	0	0	1	0	0	1	0

Despite the proliferation of nondecimal weights, measures, and currencies in the seventeenth century, the idea of exploring nondecimal number bases, as opposed to tallying systems, was not commonplace. While counting in fives, twelves, or twenties was well understood and widely practiced, the idea of counting in bases 5, 12, or 20 was not. The modern idea of a base as a positional numbering system was still coalescing. But it was glimpsed by a few. Indeed, the binary number system was independently invented at least three times in the seventeenth century: by Thomas Hariot (1560–1621) near the turn of the century (see Strickland 2023c), by Juan Caramuel y Lobkowitz (1606–1682) in 1670, and again by Leibniz c.1677–1678. Moreover, Erhard Weigel (1625–1699) proposed the quaternary or base-4 number system in 1673, and Joshua Jordaine vigorously defended the duodecimal or base 12 system in 1687 (see Weigel 1673 and Jordaine 1687). But if Leibniz's willingness to explore nondecimal number systems was not entirely unprecedented in the seventeenth century, the depth of his explorations was. He wrote in excess of a

hundred manuscripts on binary, and at least as many more in which binary is mentioned alongside other matters. There are manuscripts dealing with other nondecimal bases too. Of these riches, Leibniz chose to publish just a single paper in his lifetime: "Explanation of Binary Arithmetic," which appeared in 1705. This was enough to bind his name to the binary system in the centuries that followed, such that it was often incorrectly stated that he was its sole inventor. But of the three mathematicians who had devised binary in the seventeenth century, only Leibniz would influence the future development of base 2 and its eventual adoption by early computer engineers (see Strickland and Lewis 2022, 16–21): Hariot's manuscripts on binary arithmetic remained unknown until the 1920s (see Morley 1922) and have been published only in the last decade, while Caramuel y Lobkowitz's book was widely overlooked, being cited more in catalogues of book collections than in the work of other mathematicians.

Leibniz's decision not to publish more of his work on nondecimal number systems limited his impact; he is not, for example, generally given credit for the invention of base 16 (an honor usually given to the nineteenth-century Swedish-American engineer John Nystrom; see Knuth 1998, 202). Even today, more than 300 years after Leibniz's death, the vast majority of his writings on binary and other nondecimal number systems remains unpublished. As a consequence, many of the texts cited in this chapter are unpublished manuscripts. Since these are not generally accessible, I have quoted from them liberally. Given that the full depth of Leibniz's writings on binary and other nondecimal number systems remains to be explored, the account of them in this chapter will necessarily be incomplete but nevertheless should go some way toward showing the depth of Leibniz's engagement with nondecimal number systems.

The plan of this chapter is as follows. Section 1 takes up the oft-debated question of who may have influenced Leibniz's invention of binary. As none of the proposed candidates is plausible, I turn in Sect. 2 to the question of why Leibniz invented binary, considering both his own answer and a rather different one suggested by his earliest writings on the subject. Section 3 concerns Leibniz's subsequent development of binary, in particular his methods for converting decimal to binary and for performing the four basic arithmetic operations in base 2, as well as his ideas for binary-calculating machines and his fascination with the periodic recurrence of digits of the numbers of different arithmetic and geometric sequences expressed in binary. Section 4 focuses on Leibniz's little-known work on binary fractions and expansions, and his hope that these would throw light on irrationals and transcendental quantities. In Sect. 5, I outline the symbolic use of binary in Leibniz's philosophy, where 1 and 0 are envisaged as analogues of God and nothingness, such that binary numeration is seen as a representation of the theologically orthodox doctrine of creation *ex nihilo*. Having learned of Leibniz's binary system, a Jesuit missionary in China, Joachim Bouvet (1656–1730), suggested a correlation between binary numeration and the hexagrams of the ancient Chinese divinatory text, the Yijing. This correlation – and Leibniz's enthusiastic reaction thereto – is the subject of Sect. 6. In Sect. 7, I turn to Leibniz's invention and exploration of base 16, or sedecimal, while Sect. 8 concerns Leibniz's work on other nondecimal number

systems, in particular bases 4 and 12. The chapter concludes with an account of a hitherto unknown practical application of binary that Leibniz devised in the last year of his life. Let us begin, then, with Leibniz's potential influences.

2 Who Influenced Leibniz?

The question of who influenced Leibniz's invention of binary has been often asked and just as often has been answered inadequately. Four candidates have been proposed: John Napier (1550–1617), Francis Bacon (1561–1626), Erhard Weigel, and Juan Caramuel y Lobkowitz.[1] While none of these suggestions is tenable, examining them is worthwhile for the light it sheds on seventeenth-century exploration of different number bases and of ways to simplify calculation.

In 1617, Napier published his "location arithmetic" which employed a form of binary *reckoning* based on the powers of 2 geometric sequence – 1, 2, 4, 8, 16, 32, 64, etc. – carried out on a chessboard. The successive powers of 2, identified by letters from the classic Latin alphabet (so no j, u, or w) and then the Greek letters, are given in the margins. When multiplying two numbers, each had to be decomposed into its respective powers of 2, e.g., 37 into 32, 4, and 1, with these then converted into letters which determined where counters would be placed on the board. By moving the counters according to fixed rules, one could carry out the multiplication sum without effort, aside from having to reconstruct the product by adding up its various powers of 2, the form in which the answer was given (see Napier 1617, 115–154).

Napier's binary reckoning was shortly followed by a form of binary *information code*. In 1623, Bacon published his *De dignitate et augmentis scientiarum* [On the Dignity and Advancement of the Sciences] which contained a description of a cipher employing a biliteral alphabet, where aaaaa = A, aaaab = B, aaaba = C, aaabb = D, etc. Bacon (1623, 279) believed these cipher-characters opened the way for people to express their thoughts "by objects which may be presented to sight or hearing, provided those objects are capable of a twofold difference only, as by bells, trumpets, torches, the report of muskets, and any other things whatsoever." The suggestion was not pursued, but the principle survives in the binary code used in the Braille reading system and in the ASCII (American Standard Code for Information Interchange) character table.

The first publication of binary *notation* for numbers occurred almost fifty years after Bacon. In his *Mathesis biceps* of 1670, Caramuel y Lobkowitz included brief chapters on bases 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, and 60, in each case providing a table of numbers, details of who (if anyone) had used that system, and examples of how each number is embedded or reflected in the natural or supernatural world (Caramuel y Lobkowitz 1670, XLV–LXI). In the chapter entitled "On Binary Arithmetic," he presents a table using 0 and the letter *a* to form the sequence of numbers up to 32 expressed in binary (for example, in his notation, 17 is a00a). Despite the chapter

[1] See Couturat (1901, 473); Zacher (1973, 9–33); Tropfke (1980, 12); and Ingaliso (2017, 111–112).

title, no attempt is made to show how arithmetic would work in base 2; as such, Caramuel y Lobkowitz did not venture beyond binary notation.

However, a fully developed nondecimal *number system*, complete with arithmetic algorithms, was not long in coming. In 1673, Weigel published *Tetractys*, a small book in which he advocated for the widespread adoption of the quaternary, or base-4 system, loosely inspired by the Pythagorean tetrad, a triangular figure with four rows of 1, 2, 3, and 4 points, respectively. In a relatively detailed treatment, Weigel (1673, 16–23) outlines methods of performing all four arithmetic operations in base 4, as well as methods for the extraction of square and cube roots.

It is easy to see why the ideas of many of these thinkers have been considered as a possible influence on Leibniz's invention of binary, since all share structural features with the binary number system. But as superficially tempting as it might be to consider one or more of these thinkers as Leibniz's influence, there is no evidence that any of them were, and good reason to think that two of them were not. Manuscript evidence indicates that Leibniz became aware of Weigel's quaternary system only in 1683 (see A VI 4, 1162–1163), too late for it to have influenced his development of binary, while there is evidence that Leibniz never saw Caramuel y Lobkowitz's *Mathesis biceps* at all.[2] As for Napier and Bacon, Leibniz knew of their work but did not mention it in connection with binary. It was unlikely he was influenced by either. The similarities between Bacon's biliteral alphabet and the binary number system might be obvious to us, as we are in a position of being able to compare both, but to a seventeenth-century mind knowing only the former there would have been little reason to think of the latter, as the biliteral alphabet hardly suggests or implies a positional number system employing two digits. Indeed, Bacon's biliteral alphabet is sufficiently different from a binary number system in both form and function that the passage from one to the other would have required an enormous leap of imagination, almost on a par with that required to arrive at binary from any of the routine examples of duality or twoness with which Leibniz would have been familiar, such as matter and spirit, good and evil, and light and dark. As for the specific powers of 2 geometric sequence used by Napier, this was a common feature of mathematical works: Adam Ries (1529, n.p., chapter "Progressio") referred to it as the progression "in which one number exceeds another twofold"; Peter Ramus (1599, 177) called it the "subduple ratio," while Marin Mersenne (1644, n.p., "preface") dubbed it the "double progression" (Leibniz's own term was "double geometric progression"). In many cases, the sequence was used in case studies of how to sum portions of progressions (see Schott 1658, 636), a staple part of the medieval and early modern mathematical curriculum. But some mathematicians went further. Michael Stifel (1544, 237, cf. 31), for example, treated the sequence as an object of study in its own right, observing that addition and

[2] In 1711, decades after devising binary and only 5 years before his death, Leibniz (1768, V: 418) wrote: "Regarding Caramuel's *Mathesis biceps* [*Old*] *and New*, for which he asks ten thalers, I am unable to judge well because I have not yet seen it, and I fear it may contain vain subtleties, which is not unusual for Caramuel."

subtraction in the arithmetic sequence of natural numbers correspond to multiplication and division in the powers of 2 geometric sequence:

> Whatever the arithmetic progression does by addition and subtraction, such are the things the geometric progression does by multiplication and division...

0.	1.	2.	3.	4.	5.	6.	7.	8.
1.	2.	4.	8.	16.	32.	64.	128.	256.

Moreover, as we shall see in the next section, the powers of 2 geometric sequence was also the cornerstone of seventeenth-century investigations into both prime and perfect numbers, and some of Leibniz's earliest writings involving binary are on those subjects. The sequence was also well known to assayers, who routinely used weights in the proportion 1:2:4:8..., in order to weigh money and metals with as few weights as possible, as Leibniz often noted (Strickland and Lewis 2022, 130, 139, 195, 202). Accordingly, as the powers of 2 geometric sequence was in sufficiently wide use by mathematicians and assayers, Leibniz is no more likely to have drawn it from Napier than anyone else.

Since no plausible case can be made for thinking that any of the aforementioned thinkers influenced Leibniz's invention of binary, and there are no other likely candidates, we ought to be open to the idea that "who influenced Leibniz?" might be the wrong question to ask. A better question would be: Why did he invent it? There are two ways to answer this question: either by looking at Leibniz's own answer to it, or by looking at his earliest manuscripts on binary and seeing how it was used. In the next section, we shall do both.

3 Early Writings on Binary

In his own *ex post facto* narrative, written decades after his invention of binary, Leibniz claimed that it was conscious reflection on other nondecimal number systems that led him to think of binary, as "the simplest and most natural" base (Strickland and Lewis 2022, 138). He sometimes identified the duodecimal and the quaternary as these other nondecimal bases. While there is no evidence that he paid any attention to the quaternary system prior to encountering Weigel's defense of it in 1683 (see A VI 4, 1162–1163), there is one early writing in which Leibniz treats binary as an alternative to duodecimal: a manuscript entitled "Thesaurus mathematicus" [Mathematical Thesaurus], probably written in either 1678 or 1679. In this text, Leibniz works through various topics in arithmetic, geometry, and mechanics; near the end, he outlines how positional notation works in the decimal and duodecimal number systems before identifying binary as an alternative:

> From this outline it is clear that only these ten digits are needed: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9. Those in the first position signify the equivalent number of 1s, namely no 1s, one 1, two

> 1s, three, four, five, six, seven, eight, nine 1s. Those in the second position signify the equivalent number of *10s*, that is, 1s taken ten times; in the third position, the equivalent number of *100*s, that is, 10s taken ten times, or the squares of 10; in the fourth position, the equivalent number of *1000s*, that is, 100s taken ten times, or the cubes of 10, and so on. And in place of 10 one would be able to put any other number, for example, 12. For just as when the base a is 10, the square a^2 signifies 100 and the cube a^3 signifies 1000, so when a is 12, a^2 will be 12 times 12, that is, 144, and a^3 will be 12 times 144. But on this method, instead of the digits mentioned above—0, 1 etc. 9—two new digits would be needed in addition, one which would represent ten, the other which would represent eleven; but [the digits] 10 would signify twelve, and 100 would signify one hundred and forty four. And there are some who prefer to use this method of calculating over the common method, because 12 can be divided by 2, 3, 4, and 6; in addition, a calculation is completed with fewer digits. But the difference is not so great as to be worth abandoning the decimal progression. If anyone should want to use the binary progression, he would not need any digits except 0 and 1... But the calculation would be longer, albeit easier. (LH 35, 1, 25 Bl. 3v)

This is the only writing from the 1670s in which Leibniz mentions both binary and duodecimal. And his remarks in it do not support his later narrative that he devised binary after reflecting upon duodecimal; rather, binary is simply presented as an alternative to bases 10 and 12. Moreover, at the time of writing this manuscript, Leibniz must have developed a good understanding of binary already, given his remarks about the length and ease of calculations in base 2. Quite how good his understanding was at the time is unclear: in a marginal comment, Leibniz added, "We shall say more things about the binary progression below," though this promise is not fulfilled and the manuscript contains nothing further on the subject.

The lack of supporting evidence is one good reason to be cautious about Leibniz's *ex post facto* narrative. A second reason is that the narrative presents his invention of binary as detached from and independent of the other mathematical problems with which he was dealing at the time, as though binary emerged *sine contextu*, in what can only be described as a eureka moment. As little more can be said about Leibniz's narrative, let us consider an alternative hypothesis, that Leibniz's invention of binary – or at least binary *notation* – occurred in response to his work on three problems that exercised him in the mid-to-late 1670s, namely, devising methods and formulae to determine the divisibility of composite numbers, primality, and perfect numbers.[3] This hypothesis not only has the virtue of showing that binary developed in response to and as an aid for mathematical work with which he was already engaged, but also is supported by manuscript evidence. To illustrate, we shall consider three manuscripts, all written c.1677–1678, featuring some of Leibniz's earliest uses of binary notation. At the heart of all three manuscripts is the powers of 2 geometric sequence, which was at the forefront of Leibniz's mind at the time because of his investigations into the problems of number composition and primality. In the late 1670s, these would lead him to formulate and prove the primality test known as Fermat's little

[3] This work yielded his first publication in mathematics in February 1678, namely, the short journal article "A new observation about the way of testing whether a number is prime"; see Leibniz 1678/ http://www.leibniz-translations.com/prime.htm. For details of Leibniz's work on primes, see Mahnke (1912–1913).

theorem: $2^{n-1} - 1 \equiv 0 \pmod{n}$.[4] On his way to that, Leibniz investigated numbers of the form $2^n - 1$ (these would later be dubbed "Mersenne numbers"), as in the first of our three early manuscripts, a series of remarks about the divisibility of numbers written on the back of an envelope probably in 1678. Leibniz begins by stating the formulae $2^n - 1$, $3^n - 2$, $4^n - 3$, etc.:

> Every number exactly divides any number of the double geometric progression diminished by one.
> Every number exactly divides any number of the triple geometric progression diminished by one or two.
> Every number exactly divides any number of the quadruple geometric progression diminished by one or two or three.
> And so on ad infinitum.

(To the first statement, Leibniz later added: "false, except about a prime [number].") The manuscript continues:

> The numbers of any geometric progression can be expressed generally thus: 1, 10, 100, 1000, 10000 etc. Putting 10 means either 2 for the double [geometric progression] or 3 for the triple [geometric progression] etc. Therefore the numbers of the double geometric progression *diminished by one* can be expressed thus: 1 or 11 or 111 or 1111 etc.
> And of the triple [geometric progression] thus: 2 or 22 or 222 etc.
> And of the quadruple [geometric progression] thus: 3 or 33 or 333 etc.
> And of the decuple [geometric progression] thus: 9 or 99 or 999 etc. (LH 35, 12, 2 Bl. 4r)

Here, Leibniz uses binary numeration as an alternative way of expressing the numbers of a base (or "geometric progression"), noting that the numbers 1, 10, 100, 1000, 10000, etc. have different values depending on which base one is using.[5]

[4] In the manuscript entitled "Formarum reductio ad simplices," written 12 September 1680: "Therefore, $2^{z-1} - 1$ will be divisible by z, if z is prime" (LH 35, 3 A 4 Bl. 14r). During these investigations, Leibniz also glimpsed Wilson's theorem: $(n-2)! \equiv 1 \pmod{n}$, or in Leibniz's words: "The product of continuous [integers] up to the number which anteprecedes the given integer, when divided by the given integer, leaves 1, if the given integer is prime. If the given integer is derivative, it will leave a number which, since it has a common measure with the given integer, is greater than one" (LH 35 3 B 11 Bl. 21r). However, when testing his articulation of the theorem, Leibniz made a miscalculation that led him to add the false statement "(or the complement of 1)" after "leaves 1."

[5] In a slightly later manuscript, from 1679 (LH 35, 8, 30 Bl. 148), Leibniz again uses binary notation to illustrate his (still immature) formulation of a prime number theorem, namely, $2^n - 1$: "Let ⊙ = 111111, ☽ = 1111, ♀ = 111, ♂ = 11. ⊙ = ♀A, ⊙ = ♂B. Now ♀ and ♂ are prime among themselves, because their exponents are such, that is, their indices, or the numbers 2 and 3. Therefore A and B are not prime among themselves and necessarily will become A = ♂C and B = ♀C, and will become ⊙ = ♀♂C. $Z^z - 1$ is divisible by Z if Z is prime, and I have demonstrated this as follows: $2^2 - 1$ by 3 and $2^4 - 1$ by 5, therefore 1111 is divisible by 5 and 11 by 3 and 111111 by 7. But 11111 cannot be divided by 6, for since 11 can be divided by 3, 11111 and 11 have a common divisor, yet they are prime among themselves. And hence we have the sought-for demonstration of a reciprocal property of a prime number."

His use of binary here is purely illustrative, and binary plays no further role in his analysis (in the rest of the manuscript, Leibniz concerns himself with devising a method to determine which decimal number ending . . .991 to . . .999 is divisible by 17).

The second manuscript deals with a related matter: perfect numbers, that is, positive integers that are equal to the sum of their divisors (including 1 but excluding the number itself), such as 6 (= 3 + 2 + 1) and 28 (= 14 + 7 + 4 + 2 + 1). From the time of Euclid, investigations in this area of number theory have concentrated upon the powers of 2 geometric sequence, since Euclid's theorem of generating perfect numbers (or rather, even perfect numbers) is this: "if any number of numbers are set out successively in a double proportion [starting] from one, until the whole sum becomes prime, and this sum multiplied into the last [number] makes some number, then the [number] made will be perfect."[6] That is, if $2^n - 1$ is prime, then $2^{n-1}(2^n - 1)$ is perfect. Leibniz was reminded of this theorem when reading a 1678 dissertation on perfect numbers by Johann Wilhelm Pauli (1658–1723), who had used Roman letters to stand for the numbers of the powers of 2 geometric sequence in order to investigate the parts of perfect numbers via a sort of rudimentary algebraic calculus. Upon reading Pauli's book, Leibniz copied out Euclid's theorem then illustrated it in binary notation: "If 111 is prime, 11100 (that is, 111 by 100) is perfect (assuming 10, 100, 1000 are 2, 4, 8), production of the same thing by a different route" (LH 35 3 B 17, Bl. 2r). There is no indication here of Leibniz using binary notation to compute unknown perfect numbers, nor would that have been a realistic prospect in any case: the first five perfect numbers are 6, 28, 496, 8128, and 33550336, so using binary notation to represent any except the first two would obviously require unmanageably long strings of digits.[7]

Given the central role of powers of 2 in Leibniz's work on number composition, primes, and perfect numbers in the mid-to-late 1670s, it is easy to see why binary notation would have appealed to him. Take, for example, the number 7 expressed in binary: 111. A striking feature of this notation is that it displays the component powers of 2, as there is a 1 in the 4's position, a 1 in the 2's position, and a 1 in the 1's position. Thus, the binary value 111 is not just an alternative way of writing the decimal number 7, it is one that shows the three calculation steps $-(1 \times 2^2) + (1 \times 2^1) + (1 \times 2^0)$, that is, 4 + 2 + 1 – required to produce the number through powers of 2. In this vein, in 1686 Leibniz claimed that binary numeration is more perfect than decimal because in decimal there is no way to demonstrate from the digits 3 and

[6] Euclid, *Elements*, IX.36. That is, if p is a positive integer and $2^p - 1$ is prime, then $2^{p-1}(2^p - 1)$ is perfect.

[7] Perhaps because of this, in another manuscript on the subject, probably written in 1678, Leibniz sought to demonstrate perfect numbers using a mixture of binary numeration and algebra based thereon (so unrelated to Pauli's algebra), eventually reaching the conclusion "$2^{2z+1} - 2^z$ will be a perfect number if $2^{z+1} - 1$ is prime. Likewise, $2^{z-1} - 1$ will be divisible by z, if z is prime" (LH 35, 3 B 17 Bl. 1).

9 that $3 \times 3 = 9$, whereas in binary it is apparent (with a little working out) that $11 \times 11 = 1001$ (A VI 4, 800). And in the 1690s, when Leibniz started to provide detailed accounts of binary to some of his mathematician correspondents, he often made the point that a unique feature of binary notation is that it shows how any number can be represented as the sum of distinct powers of 2 (see A II 3, 452; Strickland and Lewis 2022, 111; 195).

Moreover, binary notation is convenient for expressing the numbers of the powers of 2 geometric sequence because these always consist in a 1 followed by 0s, e.g., $2 = 10$, $4 = 100$, $8 = 1000$, etc. And as Leibniz acknowledged in the first of our three early manuscripts above, binary notation is just as convenient for expressing the values of the Mersenne numbers, $2^n - 1$, because these always consist in 1s with no 0s, e.g., $2^1 - 1 = 1$; $2^2 - 1 = 11$; $2^3 - 1 = 111$; etc.[8] (In contemporary terminology, every Mersenne number is a binary repunit.) Therefore, binary numeration serves as a very convenient and very informative shorthand if one is working with various powers of 2, or the values of $2^n - 1$, especially for the lower values thereof, the very ones Leibniz tended to favor when illustrating his formulae.

And indeed, in our third manuscript, entitled "Calculus" [Calculation], written sometime after 1676 (but probably before 1680), Leibniz uses binary notation as one of the various ways of expressing the powers of 2. In this manuscript, Leibniz outlines elementary arithmetic terms and operations, and when he comes to "powers" he offers this:

Powers. bb is b^2, bbb is b^3, etc. $b^r b^z$ is b^{r+z}; thus, $b^2 b^3$ is b^{2+3}, that is, b^5.

1	2	4	8	16	32	64	128	256
b^0	b^1	b^2	b^3	b^4	b^5	b^6	b^7	b^8
1	b	bb	bbb	b^3b		b^{3-2}	b^{4+3}	
			b^2b	b^2b^2	b^3b^2	b^3b^3	b^4b^2	
1	10	100	1000	10000	100000	1000000	10000000	100000000

(LH 35, 4 11 Bl. 8r)[9]

The three manuscripts surveyed share a number of notable features. First, while binary *notation* may be present in all three, binary *arithmetic* is not; instead, Leibniz performs all his arithmetic in decimal or algebra. Second, binary notation is used for illustration rather than for calculation. These common features suggest that at the time of writing these three manuscripts, Leibniz was not thinking beyond the notation, and this in turn would support the hypothesis that he developed this

[8] Leibniz explicitly acknowledged these features, at least in the 1680s onward. For example: "The very last digits of a number of the double geometric progression can be easily obtained like this: if 1 is subtracted from it, then it is written in binary: etc.1111111, that is, 1 + 2 + 4 + 8 + 16 + 32 etc." (LH 35, 3 B 11 Bl. 10r; cf. LH 35, 8, 30 Bl. 75; LH 35, 13, 3 Bl. 33; LH 35, 15, 5 Bl. 10r; and LH 35, 3 B 5 Bl. 51r).

[9] A similar table is found in other manuscripts, such as LH 35, 4, 11 Bl. 10r, though this was likely written in 1681.

notation as a tool to assist his investigations in mathematical problems that were exercising him at the time.[10] Of course, given the difficulty in dating Leibniz's earliest writings on binary with great accuracy,[11] the hypothesis just sketched about binary's origins must remain speculative. But the three manuscripts are probably among his earliest writings on binary, predating the developed treatment in his earliest dated writing on the subject, "On the Binary Progression," written 15 March 1679 (on the Julian calendar, 25 March 1679 on the Gregorian).

As for when Leibniz invented binary, a precise date is difficult to fix, but the three early manuscripts outlined above were probably written in 1677 or 1678. He was certainly in possession of the idea of a binary progression, i.e., base 2, no later than February 1678, the date he wrote on a manuscript in which he floated the idea of working with various nondecimal number systems, including binary. The manuscript begins with Leibniz giving himself instructions: "Attend to other progressions, such as nines, eights, etc., starting from the lowest—twos, threes, and so on going upwards—for thus only then will a progression be apparent and even the method of confirmation, which otherwise will be difficult to procure from decimal alone" (LH 35, 3 A 24 Bl. 6r).[12] (He subsequently struck this passage out, and the rest of the manuscript concerns the reduction of fractions to decimal numbers.) An earlier date for the invention of binary is possible, since another manuscript containing a table of the numbers 0–8 in binary along with a few simple binary sums has been dated to October 1674 (see Strickland and Lewis 2022, 30). However, the material in binary – written in a different ink from the rest of the contents – was probably added later, though how much later is not known. Hence on the question of dating the invention of binary, two hypotheses may be formed: first, that Leibniz invented binary in 1674 or thereabouts, but did no further work on it or with it for another 3 or 4 years, or second, that he invented it in 1677 or early 1678.

4 The Development of Binary

Although Leibniz probably invented binary notation in response to, and as an illustrative aid for his work on divisibility, primes, and perfect numbers, it did not take him long to develop a full-blown base-2 number system. The evidence suggests this occurred in stages rather than all at once. There are many manuscripts containing rudimentary explorations of binary, such as tables of numbers and simple sums, sometimes scrawled in the margins of manuscripts on nonmathematical topics (for an example of which, see Strickland and Lewis 2022, 4). In his earliest *dated* writing

[10] Another writing in this vein is printed in Strickland and Lewis (2022, 41–43).

[11] Leibniz did not affix a date to them, and the paper contains no watermarks that could be used to determine a dating, so they have to be dated using internal evidence.

[12] Leibniz also refers to "the binary progression, where only ones and 0 express a number," in a manuscript on the construction of a universal language, tentatively dated to February 1678 (A VI 4, 68).

on binary, "On the Binary Progression," written 15/25 March 1679, Leibniz outlined algorithms for conversion between decimal and binary notation and for addition, subtraction, multiplication, and division in binary numerals. He also devised a binary algebra in order to work out the square of a 6-digit number and to extract square roots (Strickland and Lewis 2022, 48–59). Similar ground is covered in later systematic treatments, such as "Essay on a New Science of Numbers" from 1701, and "On Binary" from 1705 (see Strickland and Lewis 2022, 138–144, 206–212). Rather than attempt to plot the steps of Leibniz's increasing facility with binary, I shall focus on his methods for converting decimal to binary along with the algorithms for the four arithmetic operations, his attempts to mechanize binary calculation, and his investigations into the periodicity of arithmetic progressions expressed in binary.

Leibniz's original method for converting decimal numbers to binary was to start with a given number, for example, 47, then successively halve it, at each step noting whether 0 or 1 remains (see Strickland and Lewis 2022, 50). When the process is finished, the digits can be written in a row, where the bottommost digit is the leftmost, and the topmost digit the rightmost, i.e., in the 1s position: 101111.

47	
23	1
11	1
5	1
2	1
1	0
	1

Leibniz later devised a variation of this method, whereby one arranges the successive halves of the given decimal number in columns and then simply writes a 1 underneath an odd number and a 0 underneath an even number to get the binary equivalent:

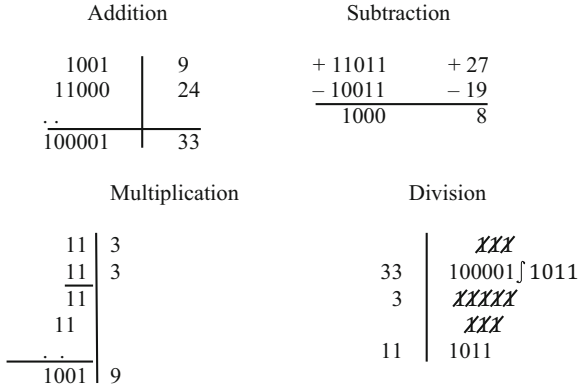
1	2	5	10	21	42	85	171	343	
1	0	1	0	1	0	1	1	1	343

(LBr 705, 69r)

The algorithms Leibniz developed for the four basic arithmetic operations are straightforward. He claimed that to perform these operations, one need know only the following:

> For *addition*, 0 plus 0 is 0. And 0 plus 1 is 1, and 1 plus 1 is 10.
> For *subtraction*, 0 minus 0 is 0, 1 minus 0 is 1, and 1 minus 1 is 0.
> For *multiplication*, only this: 0 times 0 is 0, 0 times 1 is 0, and 1 times 0 is 0, and 1 times 1 is 1.
> For *division*, I have 1 in 1 once, and I have 0 in 0 once. (Strickland and Lewis 2022, 92)

Typical examples given were:



(Strickland and Lewis 2022, 96–97)

Note here that the dots in the examples of multiplication and addition indicate a carry of 1. Note also that the example of division follows the so-called "galley" method, popular in Europe in the seventeenth and eighteenth centuries.

Leibniz later devised a shortcut when adding multiple numbers, such as:

```
    1
   11
  100
 1001
 1011
11100
```

(example simplified from Strickland and Lewis 2022, 140)

The first column on the right has four 1s, but instead of making two carries to the second column as per the standard algorithm, Leibniz realized that one could instead make a single carry to the third column (see Strickland and Lewis 2022, 140, 146, 208–209). When dealing with subtraction, Leibniz also anticipated the two's complement operation, where x – y is computed by determining the two's complement of y, i.e., the number that when added to y gives 0:

> It should also be noted that for the subtrahend number, its complement [up] to 100000 etc. can be placed, and then subtraction is not needed but only addition... As, for example:

The subtrahend is	11 0101
Supposing it should be subtracted from	100 0000
It is evident that this gives	00 1011
For if you add this:	11 0101
It gives us	100 0000

(Strickland and Lewis 2022, 51)

During his early explorations of binary, Leibniz envisaged the mechanization of the four basic arithmetic operations, jotting down ideas for binary-calculating machines of

two different designs. The first was based on his decimal-calculating machine that he had had built in 1673 (though it never worked properly). Instead of being driven by a series of cylinders with nine teeth, as per his decimal machine, the binary version was envisaged as having cylinders with four teeth, each alternately designated as 0 or 1, so that "one revolution will cause two carries" (Strickland and Lewis 2022, 45). Leibniz acknowledged that, with this machine, "the greatest difficulty is to convert a binary number into an ordinary one or vice versa" (Strickland and Lewis 2022, 45), but from his description it is clear that he envisaged conversion going only one way, for while the machine's user would enter the sum in decimal, the result would be given in binary (for more details on this machine's design, see von Mackensen 1974). The second proposed binary machine, conceived as carrying out only the operation of multiplication, is described in "On the Binary Progression." This design is of a sliding box or carriage with shutters on the underside that can be set open or closed, the whole contraption sitting atop various fixed channels representing the columns of a binary number. If a shutter is set open, then a ball is released into the channel below it, and the box is then moved by an unspecified mechanism from one channel to the next, dropping a ball into the channel below if the shutter is open and nothing if not. The process is repeated for each bit of the multiplier, and if a channel accumulates two balls, another unspecified mechanism passes one of these to the next channel on the left while the other is removed (Strickland and Lewis 2022, 52). Although Leibniz's description of this machine lacks detail, and it is doubtful he would have been able to have had it constructed, from his sketchy outline a functional replica was built in 2003/2004 (see Stein et al. 2006).

While Leibniz certainly enjoyed a flirtation with mechanization during his exploration of binary, his true infatuation was with arithmetic and geometric progressions, on account of the recurring periods of the individual digits being significantly shorter in binary than in decimal. Take, for example, the sequence of square numbers: 1, 4, 9, 16, 25, 36, etc. In decimal numeration, the last digit of the successive square numbers recurs periodically: 1, 4, 9, 6, 5, 6, 9, 4, 1, 0; switch to binary numeration and the period of the last digit of successive square numbers is drastically reduced to just two terms: 0, 1 (see below). The other columns are periodic too: Leaving aside the second column, which consists only of 0s, the third column has the period 0010, the fourth 0001 0100, etc. Leibniz's hope was that working with the shorter periods in binary notation would make it easier to determine formation laws for the periods, making it possible to calculate any term of a periodic sequence.

0	0000000
1	0000001
4	0000100
9	0001001
16	0010000
25	0011001
36	0100100
49	0110001

From the late 1670s onward, Leibniz intermittently investigated column periodicity in binary, filling many dozens of manuscript pages, often using algebraic terms to stand for period-sequences or even entire columns. To assist his efforts further, he occasionally devised new notation, though it was often abandoned immediately afterward after it failed to produce the desired breakthrough. In 1699, he introduced the parenthetical term (b) to signify logical complement, calling it "anti-b," "so that if b is 1 then (b) is 0; and if b is 0 then (b) is 1" (LH 35, 3 B 6 Bl. 1r). Two years later, he devised the notation a $\dot{+}$ b, which

> signifies the digit which is produced from the digits a + b added into one in the same column. For example, if a is 0 and b is 0, a $\dot{+}$ b will be 0. If a is 0 and b is 1, or the other way around, a $\dot{+}$ b will be 1; if a is 1 and b is 1, a $\dot{+}$ b will be 0, for a + b is 10, where the 1 is carried into the next column (LH 35, 3 B 5 Bl. 87).

So stated, Leibniz's a $\dot{+}$ b clearly anticipates the boolean exclusive-or operator $\oplus$.

Despite his efforts, the anticipated number-theoretic rewards of investigating column periodicity eluded Leibniz. He did, however, have some successes. In 1698, he observed that in the natural and triangular numbers, the first half of any period is always the complement of the second half, such that if the first half is 0000, then the second half will be 1111 (LH 35, 3 B 5, Bl. 10). And in 1701, he established that if two or more periodic sequences are added together, the resulting sequence will itself be periodic, its period determined by the periods of the two or more generating sequences (Strickland and Lewis 2022, 158–160). When Leibniz began to provide details of the binary system to mathematicians from the late 1690s onward, much of the information he provided was about column periodicity (see A II 3, 450–452; Strickland and Lewis 2002, 111, 122–124, 128–130). His hope was that others would assist in the investigations for which he had little time himself, but there were few takers. The exceptions were Theobald Overbeck (1672–1719), who corresponded with Leibniz about column periodicity from 1709 onward (see LBr 705 Bl. 23–26, 71–73; LH 35, 15, 5 Bl. 10–11), and Pierre Dangicourt (1664–1727), who at Leibniz's behest published an essay entitled "On the Periods of Columns in a Binary-Expressed Sequence of Numbers of an Arithmetic Progression" in 1710 (see Dangicourt 1710).

5 Binary Fractions and Expansions

While the majority of Leibniz's writings on binary focused on integers, he also explored binary fractions and their expansions, especially but not exclusively in the late 1670s and early 1680s. Leibniz quickly discovered that just like decimal fractions, binary fractions are either terminating, i.e., expanding to a finite number of digits, or repeating or recurrent, i.e., expanding to infinity, with a finite set of digits (the repetend, or period) repeating forever. For example:

Decimal fraction	Binary equivalent	Binary expansion
$\frac{1}{2}$	$\frac{1}{10}$	0.1
$\frac{1}{3}$	$\frac{1}{111}$	$0.\overline{01}$
$\frac{1}{4}$	$\frac{1}{100}$	0.01
$\frac{1}{5}$	$\frac{1}{101}$	$0.\overline{0011}$

Leibniz's preferred method for working out binary expansions was the galley method (mentioned above in relation to division in integers), but this often proved challenging. In one manuscript (LH 35, 13 2 B Bl. 155), Leibniz focuses on the binary expansions of the decimal fractions $\frac{1}{13}$ and $\frac{1}{17}$. While he gets the correct result – $0.\overline{000100111011}$ – for the former, for the latter he first gets the incorrect result 0.0000111 (which is in fact the binary expansion for $\frac{7}{128}$) before arriving at the correct $0.\overline{00001111}$ on the second attempt. In another manuscript, two out of seven attempted binary expansions arrive at the wrong result: for the expansion of $\frac{1}{6}$ Leibniz gets 0.001 (which is the expansion for $\frac{1}{8}$), while for $\frac{1}{9}$ he gets 0.00101, which is the expansion for $\frac{5}{32}$ (see Strickland and Lewis 2022, 62). Such mistakes are common in Leibniz's use of the galley method to determine binary expansions, and perhaps for this reason he developed various other methods, of which I shall mention two.[13]

The first is found in a manuscript from c.1679, where Leibniz describes an algorithm for finding the repetend in the binary expansion of those reciprocals whose denominator is odd, and this with "no need for actual division":

Take, for example, the fraction $\frac{1}{7}$, expressed in binary as $\frac{1}{111}$.
Add 1 to the numerator = 1001.
Take half of this = 100; this number serves as the "constant multiplier."
The last digit of the period is always 1, so write 1.
Multiply this by the constant multiplier: $100 \times 1 = 100$. Write 0 as the penultimate digit of the period, and carry the remaining 10.
Multiply the last digit obtained – 0 – by the constant multiplier: $100 \times 0 = 0$. To this, add the carry of 10: $0 + 10 = 10$. Write 0 as the antepenultimate digit of the period, and carry the remaining 1.
Multiply the last digit obtained – 0 – by the constant multiplier: $100 \times 0 = 0$. To this, add the carry of 1: $0 + 1 = 1$. So write 1. Since the remainder is now 0, the digit just obtained is the last one of the next iteration of the repetend (see LH 35, 3 B 3 Bl. 12r).

As the algorithm reveals that the period is 001, the binary expansion of $\frac{1}{111}$ is $0.\overline{001}$. After obtaining this result, Leibniz seeks to confirm it using the galley method of division, but as if trying to demonstrate the need for the alternative method just sketched, his calculation goes awry and he comes up with $0.\overline{100}$ instead.

[13] A third is outlined in Strickland and Lewis (2022, 40n2).

A second method for working out binary expansions comes from a manuscript written in 1680 (LH 35, 3 B, 5 Bl. 89). Here, Leibniz seeks to multiply known binary expansions to determine a new one. Beginning by multiplying the binary expansions of $\frac{1}{3}$ and $\frac{1}{5}$ to determine the binary expansion of $\frac{1}{15}$, Leibniz multiplies $0.\overline{0011}$ by $0.\overline{01}$ and ends up with $0.\overline{00001111}$, triumphantly proclaiming "Therefore, two periodic sequences have been added into one," before realizing the calculation has gone astray (as $\frac{1}{15}$ in fact expands to $0.\overline{0001}$). In a second attempt, Leibniz first computes the binary expansion of $\frac{1}{9}$, namely, $0.\overline{000111}$, then tries to reach the same result by multiplying the binary expansion of $\frac{1}{3}$ by itself. This time, he gets the correct result, stopping at 0.000111000111.

Some of Leibniz's earliest explorations with binary fractions and expansions concern irrationals. In "On the Binary Progression," he computes the first digits of $\sqrt{2_{10}}$, getting the result $1.011010100..._2$. In order to confirm his result, Leibniz then multiplies that number by itself, obtaining the value 01.111111111110100, noting that as the infinite numeral [0].1111111... represents 1, so 1.1111111 represents 2 (Strickland and Lewis 2022, 58). In another manuscript, probably from 1680, he repeats the process, this time obtaining several more digits of $\sqrt{2_{10}}$: 1.0110111101 (LH 35, 8, 30 Bl. 125v). The aim of such exercises was not to find a periodic sequence of digits – Leibniz was well aware that irrationals did not have such[14] – but to show that irrationals could be "determined as far as possible" through binary (Strickland and Lewis 2022, 54). His hope was to find "laws of sequences which not only seem not to have a period but also really do not have one. Such are those which correspond to irrationals. For not all laws of sequences are periods" (LH 35, 13 3 Bl. 33r).

In a similar vein, Leibniz hoped that binary could offer insight into transcendental quantities, most notably the alternating converging series that now bears his name: $\frac{1}{1} - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \frac{1}{11} + \frac{1}{13} - \frac{1}{15} + \frac{1}{17} - \frac{1}{19}$, etc. The series, discovered in 1674, was the key result of his investigation into the classic problem of squaring the circle, that is, determining the area of a circle enclosed by a 1×1 square. After discovering the series in 1674, Leibniz for a time entertained hopes that it might prove to have a finite sum (as some infinite series of reciprocals do, for example, that of triangular numbers $\frac{1}{1} + \frac{1}{3} + \frac{1}{6} + \frac{1}{10} + \frac{1}{15}$, etc. sums to 2), but these had dissipated by the time he had invented binary. Nevertheless, he believed that investigating the periodicity of these fractions in binary could yield a rule that would enable one to continue the expansion of the digits of π: "Having obtained the period from a given number, one will also obtain the method of expressing by a certain rule the sequence of digits expressing the size of a circle, that is, $\frac{1}{1} - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9}$ etc." (Strickland and Lewis 2002, 59). As such a rule eluded him, in August 1680 Leibniz tried out a different approach in a manuscript entitled "Attempted Expression of the Circle in Binary Progression" (Strickland and Lewis 2022, 61–62). Here, Leibniz considers the powers of 2^{-1} geometric sequence, namely, 1, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, $\frac{1}{32}$, $\frac{1}{64}$, etc. (unhelpfully

[14] Although in one early writing he exclaims that binary will be "remarkable for periodic progressions in expressible quantities which are not whole or rational" (Strickland and Lewis 2022, 32).

also called "binary progression"), comparing various terms of this sequence with sequences of terms from his circle formula. However, a calculation error early in the process led him to incorrectly conclude that $\frac{1}{2}+\frac{1}{4}$ is greater than the area of the circle (which, if true, would make π less than 3). Failing to spot the mistake, which subsequently gets compounded, Leibniz eventually gave up.[15]

In the last twenty years of his life, Leibniz outlined binary notation and arithmetic to many of his mathematician correspondents, but he was not similarly forthcoming about his work on binary fractions and expansions, electing to keep this to himself. However, he did suggest to a few correspondents the idea of exploring π using binary. In 1704, Leibniz informed Jakob Hermann (1678–1733) of his hope that a rule would be found to enable the digits of π to be computed, describing this as something "we will obtain more easily through binary" (GM IV 266), though he did not elaborate on this remark. The following year, he made the same suggestion to Jacob Bernoulli (1655–1705), who took the bait and presented Leibniz with a 118-digit binary representation of the first 36 decimal digits of π:

$$11110010000001001111110110011000110110110110011000010011110010010110010101101101101010001101110010101000000011110100000_0^1$$

There are a number of problems with this result. First, Bernoulli, apparently not realizing the significance of the radix point, simply converted the integer 31415926535897932384626433832795028 into binary, rather than the fraction $\frac{31415926535897932384626433832795028}{10000000000000000000000000000000000}$, so he did not express π in binary at all. Second, his 118-digit binary number is actually equal to the integer 31415926535897932384626433832792980 8, which is short by 20480, indicating that he dropped some bits in his calculation (for more details, see Knuth 1983, 238). Bernoulli did at least get one thing right, noting of his binary number that "no period of digits is apparent here, nor any law of the progression" (GM III/1, 97). In his response, which made no mention of Bernoulli's errors, Leibniz clung to the view that the law of progression of π was simply hidden and probably more easy to detect in binary than in decimal (GM III/1, 101).

6 Binary and Philosophy

Leibniz's faith in the illuminatory power of binary is nowhere more evident than in his use of it in philosophical theology. In 1694/1695, when sketching notes on one of Weigel's books, Leibniz devised an analogy between the representation of all numbers by 1 and 0 and the theologically orthodox idea of creation *ex nihilo*, that is, the creation of all things out of nothing by God. Treating God as the analogue of 1 and nothingness as the analogue of 0, Leibniz took the origination of all numbers

[15] For further details of Leibniz's work on the binary expression of his circle formula, see Strickland (2023a).

from 1 and 0 in binary as a reflection of the doctrine that all created things originate from God and nothingness. This analogy would play a pivotal role in Leibniz's willingness to inform correspondents about binary from 1696 onward (and as we shall see in Sect. 6, this in turn played a pivotal role in his decision to publish an essay on binary in 1705).

To understand Leibniz's binary-creation analogy, note that in his metaphysics, all created beings contain the same perfections as God (namely, power, wisdom, and goodness), albeit not to the same degree, because, as created beings, they have limitations or privations. In this sense, all created beings originate both from God, the source or principle of their perfections, and from nothingness, the source or principle of their privations or imperfections. Hence:

> According to the binary [progression], all numbers are expressed by the digits 0 and 1 alone, by unity and nothing, a remarkable analogy of the origin of created things from God and nothing, with creatures having their own perfections from pure, positive actuality, or God, and their imperfections or limits from the negative, or nothing. (Strickland and Lewis 2022, 85)

Such remarks can easily be read as saying that created things are literally composed of two distinct but seemingly mutually exclusive elements, such that it is difficult to see how they could coexist in one and the same being. Leibniz clarifies:

> there are in him [God] three primacies: power, knowledge and will; the result of these is the operation or creature, which is varied according to the different combinations of unity and zero; or rather of the positive with the privative, for the privative is nothing other than limits, and there are limits everywhere in a creature, just as there are points everywhere in the line. However, a creature is something more than limits, because it has received some perfection or power from God, just as the line is more than points. For ultimately the point (the end of the line) is nothing more than the negation of the progress beyond which it ends. (Leibniz 2006, 39)[16]

Leibniz thus envisaged the creation of something from nothing as involving God divesting a finite portion of his essence to the creature and then *stopping*, the stopping point marking the limit of the creature. As such, Leibniz should not be understood as claiming that nothingness is an element of the creation process; rather, the reference to nothingness is a poetic way of referring to a limit, the idea that a creature contains some of God's essence but not all. A created thing should not be construed as literally a mixture of God's essence and nothingness, but rather as a finite instantiation (or dilution) of the former.[17]

[16] Also: "Without doubt boundaries or limits are of the essence of creatures, but limits are something privative and consist in the denial of further progress." Leibniz (2006, 38), cf. A I 15, 369; Leibniz (2006, 102–103); and Strickland (2014, 22).

[17] Or as he puts it in a manuscript written perhaps in 1695 or possibly in 1702, "things are educed from God's active power—as Julius Scaliger said—rather than from passive nothing. My invention of the composition of numbers from 0 and 1 would wonderfully support this doctrine" (LH 4, 3, 5e Bl. 5). See Scaliger (1557, fols. 16–17).

Clarifying the analogy in this way does not prevent it from being inapt, however. In binary numeration, all numbers are composed from two elements (0 and 1) by compounding them in ever longer strings, whereas Leibniz envisaged all created things arising from God through an entirely different process, in which God divests some of his own essence to a creature, so that in terms of essence, or perfection, each creature is greater than nothingness but less than God, i.e., it has the same qualities as God but not to the same degree as God. Because of this, it would make more sense to say that all created things are analogues of binary fractions, each having a unique expression of their perfection and limitations in the same way that all fractional numbers between 0 and 1 are uniquely expressed in binary. Leibniz did not frame his analogy in this way, however.

Once the binary-creation analogy had been devised, Leibniz quickly recognized its philosophical value. It next appeared in December 1695, in the middle of a brief sketch of a planned book entitled *Theodicy*, envisaged as a defense of God's justice in response to the world's evil. The sketch reveals Leibniz's belief that the binary-creation analogy could help explain why created beings are liable to sin, i.e., because, by virtue of being limited, they fall short in the perfections of power, wisdom, and goodness:

> New studies: concerning the original imperfection of creatures before sin, from which the cause of sin is to be sought. All things are good but nothing is absolutely perfect. Concerning the composition of things from perfection and limitation, i.e. from action and privation, and concerning the origin of things from God and nothing, in which concerns the origin of numbers from 1 and 0, i.e. from unity and nothing. (LH 1, 6, 2 Bl. 20r/http://www.leibniz-translations.com/theodicaea.htm)[18]

With the binary-creation analogy now envisaged as a key part of his philosophical theology, Leibniz sought to promulgate both it and the number system on which it was based. In early May 1696, he discussed it with Rudolph August, Duke of Brunswick and Lüneburg (1627–1704). The duke's warm reception of the analogy prompted Leibniz to pitch the idea of commemorating it on a medal, to be struck at the duke's command. Various designs were sketched (for which see Strickland and Lewis 2022, 103), but the duke decided to commemorate the binary-creation analogy in a different way: by commissioning three wax seals (for which see Strickland and Lewis 2022, 106).

Believing that the binary-creation analogy had the potential to make the Christian doctrine of creation *ex nihilo* intelligible and even plausible to non-Christians, Leibniz communicated it – with attendant details of the mathematics of binary – to two Jesuit missionaries in China, Claudio Filippo Grimaldi (1638–1712) in 1697 and Joachim Bouvet in 1701 (see Strickland and Lewis 2022, 108–115, 126–134). While the former did not respond, the latter famously suggested a correlation between Leibniz's binary numeration and the sixty-four hexagrams of the ancient Chinese

[18] When Leibniz did come to write the *Theodicy* more than a decade later, the binary-creation analogy was not mentioned. The *Theodicy* was published in 1710. See Leibniz (1985).

divinatory text, the Yijing (or Book of Changes), a suggestion that would prompt Leibniz to go public with his invention.

7 Binary and The Yijing

The Yijing consists of sixty-four individually named hexagrams, each accompanied by a short, enigmatic essay. The hexagrams themselves consist of six stacked horizontal lines, each line being either unbroken (representing yang) or broken (representing yin). From these two elements, arranged in all possible groupings of six, emerge the sixty-four hexagrams. Bouvet had been a student of the Yijing for many years before he learned of Leibniz's binary arithmetic, and had already suspected that it somehow encapsulated "a numerary metaphysics" that, when properly deciphered, would reveal the perfected science of the ancient Chinese (A I 20, 573). Upon learning of Leibniz's binary arithmetic, Bouvet hypothesized that the hexagrams had been intended as a binary number system.

To see what Bouvet saw, and thus to understand his hypothesis, we need to consider the hexagram-sequence he sent to Leibniz. This is the so-called "Fuxi sequence," named after the mythical Chinese philosopher-emperor traditionally believed to be the author of the Yijing. The first sixteen hexagrams of the Fuxi sequence are:

䷀ ䷁ ䷂ ䷃ ䷄ ䷅ ䷆ ䷇ ䷈ ䷉ ䷊ ䷋ ䷌ ䷍ ䷎ ䷏

Let us start with the component lines of each hexagram. Bouvet equated – albeit without justification – the broken line with 0 and the unbroken line with 1. If we replace the lines with binary digits in the way Bouvet suggested, the hexagrams are converted thus:

000000 000001 000010 000011 000100 000101 000110 000111 001000 001001 001010 001011 001100 001101 001110 001111

Rotating the digits 90° clockwise gives us the decimal numbers 0–15 in binary notation. From this, it is clear that Bouvet read each hexagram from the bottom line upward, such that he took the bottom line to represent the leftmost digit (32's place) of a six-digit number in binary, the next line up to represent the leftmost-but-one digit (16's place) and so on, such that the hexagram ䷆ would be equivalent to 000110 in binary (6 in decimal).

Various problems have been noted both with Bouvet's approach to reading the hexagrams and with his hypothesis more broadly (see Zacher 1973, 112; Zhonglian 2000; Swetz 2003, 288–289; Sypniewski 2005). Here it will be sufficient to mention just one, namely, that the sequence of hexagrams upon which Bouvet based his hypothesis – the so-called "Fuxi sequence" – is a relatively modern rearrangement (by the eleventh century philosopher Shao Yong) of a much older and more

traditional sequence, namely the King Wen sequence. Bouvet neglected to mention this to Leibniz, though as a long-time student of the Yijing, he would at least have been aware of the King Wen sequence. Bouvet's omission is problematic because while the arrangement of hexagrams in the Fuxi sequence may support the idea that the hexagrams were intended as a binary number system, that of the King Wen sequence does not. The first sixteen hexagrams of the King Wen sequence are:

䷀ ䷁ ䷂ ䷃ ䷄ ䷅ ䷆ ䷇ ䷈ ䷉ ䷊ ䷋ ䷌ ䷍ ䷎ ䷏

Here, there is no prospect of seeing an orderly sequence of numbers expressed in binary. If we again take an unbroken line to be 1 and an unbroken line to be 0, and thus treat each hexagram as representing a number expressed in binary, the order of numbers in the King Wen sequence would be 63, 0, 34, 17, 58, 23, 16, 2, 59, 55, 56, 7, 47, 61, 8, and 4. Little wonder that Leibniz, seduced by Bouvet's hypothesis of a correlation with binary arithmetic, concluded that the King Wen sequence – which he had seen in a Latin book about Confucius (namely, Intorcetta et al 1689, xliv) – was a scrambling of the true order (Strickland and Lewis 2022, 187).[19]

Leibniz was so intoxicated by the idea of his binary system being the key to deciphering an ancient Chinese enigma that he related Bouvet's hypothesis to many of his correspondents, even informing Pope Clement XI (see A I 23, 353). Bouvet's hypothesis also prompted Leibniz to go public with the binary system at long last. Days after receiving Bouvet's letter, Leibniz wrote a short paper, "Explanation of Binary Arithmetic," in which he outlined binary numeration and arithmetic as well as Bouvet's hypothesis (Strickland and Lewis 2022, 195–197).[20] The paper was read at the Académie Royale des Sciences in Paris, and published in its annual periodical for 1703 (though the volume did not appear until 1705). This paper was the only one of Leibniz's hundreds of writings on binary to be published in his lifetime.

8 Sedecimal

Leibniz's "Explanation of binary arithmetic" is also notable for containing the first published reference to base 16, though this is often overlooked. Leibniz's experiments with base 16 in fact began in 1679, giving him clear priority over the English schoolmaster Thomas Wright Hill (1763–1851) and the Swedish-American engineer John Nystrom (1825–1885), both of whom independently reinvented it in the nineteenth century (see Hill 1850, Nystrom 1862, 1863).[21]

[19] There are other sequences of hexagrams apart from the two mentioned already, such as the Eight Palaces sequence, which predates the Fuxi sequence. These sequences have elicited many studies of their structure, interrelation, and history, though such matters are outside of the scope of this chapter.

[20] For more information on Bouvet's hypothesis and Leibniz's reaction thereto, see Kempe (2022, 141–174).

[21] For more information about the history of base 16, and Leibniz's place therein, see Strickland and Jones (2023).

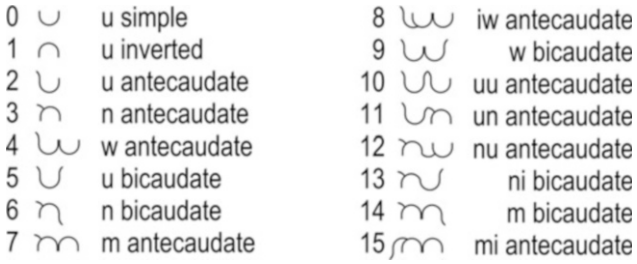
Initially, Leibniz's term for base 16 was "sedecimal," though on occasion he called it "sedenary" (the former means "sixteen," the latter "sixteen-fold," or "in sixteens"). He devised no fewer than six different forms of notation for sedecimal. In his first writing on the subject (Strickland and Lewis 2022, 64–68), he used the Roman letters m, n, p, q, r, and s for the six extra digits, before abandoning them in favor of the six Aretinian syllables ut, re, mi, fa, sol, and la, abbreviated to u, r, m, f, s, and ℓ. By combining these syllables with the German words for numbers, he created an entirely new set of terms for values expressed in sedecimal. For example, "utzwanzig," a combination of the syllable "ut," standing for 10, and the German word "zwanzig," which traditionally meant 20 but was repurposed by Leibniz to stand for 32, was Leibniz's term for the decimal number 42 expressed sedecimally.

Leibniz's later experiments with sedecimal notation were more elaborate. In one manuscript, he stacked dots and dashes, using a dot for each 0 bit and a dash for each 1 bit, with the most significant bit at the top and the least significant bit at the bottom:

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
•	–	–	–	–	–	–	–	–	–	–	–	–	–	–	–	– •
		•	–	•	•	–	–	•	•	•	•	–	–	–	–	
				•	–	•	–	•	•	–	–	•	•	–	–	
								•	–	•	–	•	–	•	–	

(Strickland and Lewis 2022, 70)

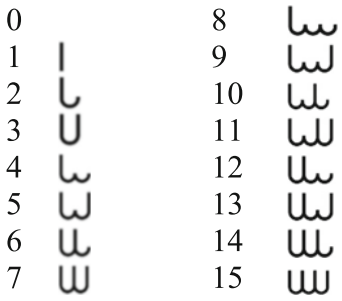
A further set of novel sedecimal digits were scrawled on the back of an envelope c.1682. This time, he starts with a concave-up semicircle to denote 0, a concave-down semicircle to denote 1, and then modifies these characters to create the remaining digits:



(Strickland and Lewis 2022, 78)

The accompanying descriptions (or instructions) indicate that Leibniz based each digit on Roman letters, either single or joined-up, with some of them being "bicaudate," that is, extended by a tail on either side, and others "antecaudate," that is, extended by a tail on the left-hand side alone.

Almost twenty years later, Leibniz devised yet another form of sedecimal notation, with the characters loosely based on the Roman letters i, u, and w, some extended with one or two right-hand tails:



(Strickland and Lewis 2022, 130)

Leibniz's sixth and final form of notation for sedecimal appears in a manuscript featuring a table of decimal numbers 0–40 represented in every base from 2 to 16 (LH 35, 3 B 11 Bl. 11v). Here, Leibniz uses the Arabic numerals 0–9 and lower-case Roman letters a, b, c, d, e, and f for the six extra digits, anticipating the modern convention, which employs the same six letters, usually in upper-case.

Shortly after having invented base 16, Leibniz arrived at the view that while binary is for theory, sedecimal is for practice (Strickland and Lewis 2022, 70). Thereafter, he occasionally suggested that sedecimal would be the ideal choice if practice were to be changed. To justify this, he used what may be termed an argument from economy, namely, that as values expressed in sedecimal are shorter than those expressed in decimal, sedecimal is more convenient. The argument is illustrated only in his very first writing on sedecimal, where he converts the decimal number 1679 (representing the date of writing) into the sedecimal number 68ℓ (equivalent to 68F in modern notation), leading him to conclude: "From this it is apparent that sedecimal expressions are much shorter" (Strickland and Lewis 2022, 64). Subsequent conversions, such as 10000 to 2710_{16} and 100000 to $186u0_{16}$, secure the point that sedecimal expressions tend to be shorter than decimal, though Leibniz's conclusion that they are "much shorter" is difficult to draw from the examples he gave, each of which compact the expression by a single digit.[22] Nevertheless, he continued to use the argument from economy to support the practical advantage of sedecimal, most notably in his published essay "Explanation of Binary Arithmetic," where he noted in passing that decimal has an advantage over binary because its numbers are not as long, but "if we were accustomed to proceed by twelves or sixteens, there would be even more benefit" (Strickland and Lewis 2022, 196). Hill and Nystrom, later advocates of base 16, also used the argument from economy, but both believed the chief advantage of base 16 lay in the fact that 16 allowed for more convenient bisections of the sort that were routinely required in shops and trade, an argument Leibniz himself did not articulate (though he could not have been unaware of it, since in the passage from "Thesaurus mathematicus" quoted in Sect. 2 above, he noted that an advantage of duodecimal is that it allows for divisions by 2, 3, 4, and 6). Moreover, while these later advocates of base

[22] The same conversion of 100000 to $186u0_{16}$ is also found in a contemporaneous text: LH 35, 8, 30 Bl. 148r.

16 envisaged and argued for a wholesale switch away from decimal, with weights, measures, coinage, and (in the case of Nystrom) even the day and the year being divided into 16 units, Leibniz's own preference for sedecimal did not extend beyond wistful thinking about reforming "practice" without indicating how far this should go. Consequently, his advocacy of base 16 was neither forthright nor vociferous, as Hill and Nystrom's would be, and Leibniz conceded that since decimal was so widely accepted, we should be satisfied with it (Strickland and Lewis 2022, 85).

9 Other Nondecimal Number Systems

Leibniz's flirtation with sedecimal shows that his engagement with nondecimal number systems was not exhausted by binary, even if that was his predominant focus. But in contrast to his writings on binary, Leibniz's writings on other nondecimal systems are occasional, scattered, and unsystematic. I have already mentioned Leibniz's 1703 sketch of table of decimal numbers 0–40 represented in every base from 2 to 16 (LH 35, 3 B 11 Bl. 11v). The table may have been intended as a ready reckoner of sorts, and no doubt came in useful as such when in the same year he sought to apply his formulation of Fermat's little theorem, $2^{n-1} - 1$, in various other number bases, such as the septenary, octonary, and nonary (LH 35, 3 B 11 Bl. 9–10). However, such ventures outside of decimal and binary were rare, and aside from binary (and to a lesser extent, sedecimal), most of Leibniz's other references to nondecimal number systems were to bases 4 and 12.

References to base 4 start to appear in Leibniz's writings from 1683 when he read Weigel's *Tetractyn*. Leibniz made brief reading notes on Weigel's book; these consist mostly of verbatim reproductions of Weigel's reasons for thinking four the most natural base but conclude with a cryptic assessment that refers to bases 2, 3, and 8: "I think the binary is best absolutely, the ternary in planes, and the octonary in solids" (A VI 4, 1163). In critical reading notes on another of Weigel's books in which the quaternary system is outlined, Leibniz offers this assessment:

> As far as quaternary arithmetic is concerned, I think that if anything were to be changed in practice, it would be to use the duodecimal or sedecimal instead of the decimal, for the larger the numbers used by a progression, the more convenient the calculation... As for theory and the discovery of extraordinary truths in arithmetic, which may likewise be very useful for practice, I think that not only should the quaternary be preferred to the decimal, but also that preferable to the quaternary in turn is the binary, which is the most perfect of all, nor does it suppose anything but instead completely resolves numbers. (Strickland and Lewis 2022, 85)

This is as close as Leibniz came to a comparison of the relative merits of the binary and quaternary systems. Thereafter, he often mentioned Weigel's advocacy of base 4, but invariably in passing when writing about binary (see Zacher 1973, 353; Strickland and Lewis 2022, 110). It would be fair to say that he had little interest in the quaternary system itself, opting to mention it only as a pretext for discussing and extolling the merits of binary.

To some extent, the same is true of the duodecimal system which, like Weigel's quaternary, is often mentioned in passing in the preamble when Leibniz outlines binary

to a correspondent for the first time (see Zacher 1973, 353; Strickland and Lewis 2022, 110). However, Leibniz's engagement with duodecimal goes back further and is occasionally deeper. The earliest mention of duodecimal in Leibniz's writings is in a preface he wrote in 1670 to an edition of the writings of the Italian humanist Marius Nizolius (1498–1576). There he considers the view of those who would have it that truth depends upon the definitions of terms, and definitions of terms in turn upon the human mind (in other words, that truth is arbitrary). To this, Leibniz (1969, 128) responds: "In arithmetic, and in other disciplines as well, truths remain the same even if notations are changed, and it does not matter whether a decimal or a duodecimal number system is used." Unfortunately, Leibniz does not reveal where he had learned about duodecimal, though his use of it suggests he thought it was sufficiently well known that educated readers would be able to understand his argument.

Other early writings hint at explorations of duodecimal. In a manuscript written around 1678, Leibniz noted that if the duodecimal system were used, the arithmetic checking method known as casting out nines "could become the proof by casting out elevens" (LH 35, 4, 13 Bl. 21). In the spring of 1680, Leibniz met the Dutch mathematician Johann Jakob Ferguson (1630–1706) and must have mentioned both binary and duodecimal to him, as in the scratch paper upon which both recorded their ideas, Leibniz wrote out a table showing the values of the decimal numbers 0–8 in binary, and a set of duodecimal digits, with the two extra digits given as ~ and $ (A III 3, 137). (In passing, it should be noted that on the same scratch paper Leibniz also worked out $\frac{1}{2}$ in base 11: "$\frac{1}{2} = \frac{555\ 555\ \text{etc.}}{1\ 000\ 000}$"; A III 3, 138). And in August of 1680, Leibniz noted: "It is well known that all fractions can be expressed by an infinite sequence of integers of a certain progression, for example, the decimal, or even the duodecimal, or the one I prefer overall, the binary" (LH 35, 13, 3 Bl. 33). The remainder of this manuscript is concerned with binary fractions, but given the confidence of his remark here, it is likely that he had already undertaken some investigation of duodecimal fractions. If he had, his work on that remains to be discovered.

Leibniz often claimed that some people had preferred duodecimal to decimal, but it is not certain who he had in mind. In a manuscript from 1712, he claimed that a proponent of duodecimal had been identified by the German mathematician Daniel Schwenter (1585–1636): "In the German *Deliciae mathematicae*, someone is reported to have given preference to the duodecimal progression, in which eleven digits will be needed, namely 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, δ, ε, where δ is 10 and ε is 11" (LBr 705 Bl. 93r).[23] Having identified an unnamed proponent of duodecimal, Leibniz proceeds to describe algorithms for converting decimal numbers into duodecimal:

> Lay out the twelvefolds: 1, 12, 144, 1728, 20736 etc. Now, the aforementioned number, 1712,[24] is to be expressed duodecimally. The largest of the twelvefolds lower than 1712 itself, namely 144, is subtracted as many times as possible, that is, it [i.e. the number 1712] is

[23] Leibniz is probably thinking of Schwenter's *Deliciae physico-mathematicae* [The Charms of Physico-Mathematics] of 1636, which was posthumously revised and expanded by Georg Philipp Harsdörffer (1607–1658) in 1651 and again in 1653. However, as far as I have been able to tell, in none of those works is there any mention of duodecimal, let alone any report of anyone endorsing it.

[24] Leibniz actually wrote "1728," but this is clearly a mistake as his example uses 1712.

> divided by 144; the quotient will be 11, or ε. The remainder is 128, and that is divided by the next lowest twelvefold, 12, and the quotient will be 11 with a remainder of 6. And 1712 will be εε6 = 6 + ε ×12 + ε. However, if anyone wants to accomplish this without the list of twelvefolds, divide the number 1712 by 12, then divide the quotient, 142, by 12; the quotient, 11, cannot likewise be divided by 12, therefore the largest twelvefold is 12 × 12 or 144, by which 1712 is divided to produce 11 with a remainder of 128. Divide this [remainder] in turn by 12 to produce 11 with a remainder of 6. This [remainder] cannot be divided by 12, therefore 1712 = 6 + 11 × 12 + 11 × 144 = εε6 (LBr 705 Bl. 93r).[25]

This passage represents Leibniz's deepest engagement with duodecimal aside from a single manuscript exclusively devoted to it, probably written in 1695 (LH 35, 12 1 Bl. 40r/Strickland 2022). That manuscript begins with the observation that, in the decimal system, the digital root (that is, the digit sum) of multiples of nine is always nine, e.g., 9 × 3 = 27, and 2 + 7 = 9. Leibniz then generalizes this to any number base, or "progression," supposing that for any base n, the digital root of multiples of $n - 1$ is always $n - 1$. He illustrates this in duodecimal, showing that the digital root of any multiple of 11 is always 11, or rather, since he here uses the Greek letters χ and φ for 10 and 11 respectively, any multiple of φ is always φ. To secure the point, Leibniz draws a large table of duodecimal numbers in which his "new notation" for duodecimal is shown alongside the "old meaning" (i.e., the decimal equivalents).

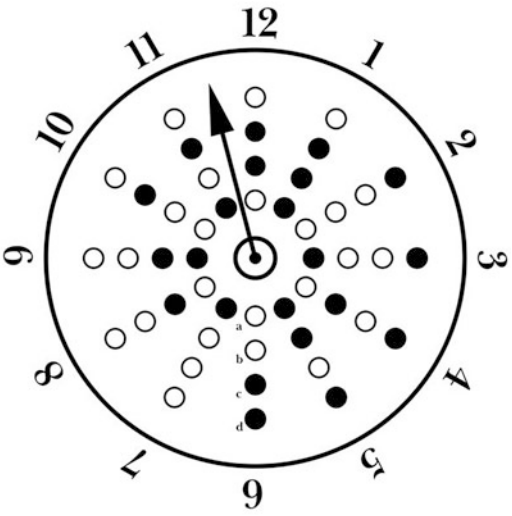
10 Conclusion

The depth as well as the breadth of Leibniz's explorations of nondecimal number systems is quite remarkable in itself, and even more so against the backdrop of a widespread lack of interest in – and awareness of – such systems among the mathematicians of his time. This backdrop no doubt contributed to Leibniz's unwillingness to go public with many of the ideas discussed in this chapter, most of which were groundbreaking at the time. However, it is worth noting that he saw fit to publish only a tiny fraction of what he wrote in any field; his writings on nondecimal number systems were no exception in that regard.

Leibniz never gave up his hope that binary would help unlock the innermost secrets of numbers. Success eluded his efforts. Yet while he cleaved fast to the belief that binary would eventually prove to be an invaluable tool for number-theoretic investigations, he did not dismiss the possibility of practical applications altogether. Indeed, in 1716, the last year of his life, he hit upon an innovative application of binary that has remained unknown till now. In a single-page manuscript (LBr 916 Bl. 44r), Leibniz sketched out a plan for a tactile clock based on binary reckoning that would enable one to tell the time at night. His illustration shows a single hour hand that moves around the clock face. Between each numeral and the center is a row of four points, each of which is either hollow (represented by an empty circle) or bumpy

[25] After this example, Leibniz turned to the quaternary system, efficiently sketching out the steps required to convert the decimal value 1712 to 122300_4 (LBr 705 Bl. 93r). He then did the same with binary, before turning to the periodicity of columns in binary.

(represented by a filled circle). Hollow points denote 0, and bumpy points denote 1 if they occur in the first position, 2 in the second, 4 in the third, and 8 in the fourth, with positions being counted from the center outward to the edge. The idea is that you feel for where the hand points, then trace your finger from the tip of the hour hand down toward the center and then further down along the same line until you encounter a row of four points, which are then read by touch. Hence in the diagram, a is 0, b is 0, c is 1, and d is 1, and since c and d are in the third and fourth positions, they denote 4 and 8, respectively. Add them together, and one knows that the time is 12 o' clock.



A casual glance at the clock face will reveal a mismatch between numerals and binary representations, as the row of holes and bumps leading from each numeral to the center contains the binary representation not of that numeral, but of the one on the opposite side of the clock (e.g., the row between the numeral 7 and the center is ooo•, which is the binary representation for 1, and vice versa). The reason for this, of course, is that the clock face is not meant to be *seen*, only touched – the row of dots one reads is the one directly opposite where the hour hand happens to be pointing, not the one that would be underneath the hand (which would not be accessible to touch anyway, because the hour hand would be over it).

Leibniz's tactile clock is as simple as it is ingenious, and the idea is all the more remarkable because it precedes the cognate inventions of night writing and Braille by more than a century.[26] In the manuscript, Leibniz says nothing about the clock's mechanism, but this would have been easy enough for a horologer of the day to construct.[27] Yet Leibniz appears not to have commissioned the clock, despite its

[26] For further details of Leibniz's tactile binary clock, and an English translation of the manuscript, see Strickland (2023b).

[27] Leibniz himself had devised a spring-driven pocket watch in the mid-1670s and continued to improve it even four decades later; see Leibniz 1675, and LH 38 Bl. 274–275.

potential to benefit not only those in ill-lit rooms at night but also the blind and visually impaired. Accordingly, his tactile binary clock is much like the majority of his other ideas about binary and other nondecimal number systems, in that it was destined only for the admiration of future generations rather than the benefit of his own.

Acknowledgments The author would like to express his gratitude to the Gerda Henkel Stiftung, Düsseldorf, for their award of a research scholarship (AZ 46/V/21), which made this chapter possible. The author would also like to thank Daniel J. Cook, Donald E. Knuth, and Harry R. Lewis for their helpful comments on an earlier version of this chapter; Siegmund Probst and Julia Weckend for their assistance in transcribing manuscripts and their illuminating discussion thereof; and Lisa Silva – @lisa_cs8 – for her illustration of Leibniz's tactile clock.

Abstract

There were two radically different algebras practiced in Europe in the time of Fermat and Descartes. One was the traditional cossic algebra grounded in arithmetic whose roots stretch back to al-Khwārizmī and Diophantus, and the other was the new geometrical algebra of François Viète. Both Fermat and Descartes chose to work in the latter. To understand their choice, and to determine how they understood their algebraic terms, we first outline the conceptual foundations of the two algebras, one that regards a monomial as a premodern number in which

the coefficient is a multitude and the power is a kind, and the other that regards a monomial as the product of two magnitudes, one known and the other unknown. We find that cossic algebra could not have been modified to include undetermined coefficients, and thus would have been inadequate for the purposes of Fermat and Descartes. Further, both authors, when solving problems in geometry, worked with precisely the same non-arithmetized algebra as Viète, without a unit measure, respecting dimension, and using magnitudes of arbitrarily high dimension for which no justification is provided.

Algebra, premodern algebra · Modern algebra · Michael Stifel · François Viète · Pierre de Fermat · René descartes

1 Introduction

Algebra played a limited role in mathematics prior to the seventeenth century. Along the path from Greek to Arabic to European algebra, it had remained a numerical technique for finding unknown numbers in problem-solving. Algebraic language and notation were not used to state arithmetical identities like $(a+b)^2 = a^2 + b^2 + 2ab$, formulas like $A = \pi r^2$, curves like $y = x^2 + 1$, or physical laws like $d = \frac{1}{2}gt^2$. For those purposes, arithmetical or geometrical language was used. Apart from rare applications in proofs in some Arabic authors (Oaks 2019), algebra concerned itself solely with the setting up and solving of equations to find the values of unknowns. While several authors such as al-Karajī and Bombelli had studied different aspects of algebra from a more theoretical viewpoint, these investigations remained internal to algebra as a problem-solving technique. This started to change in the first half of the seventeenth century, when Pierre de Fermat and René Descartes independently began to study curves through equations. Each of them discovered independently how curves can be represented by equations in two unknowns, and they both found ways to apply algebra to problems of determining normal and tangent lines to curves. These were among the first steps in what would eventually lead to the wholesale algebraization of mathematics, and by association of science as well.

In this chapter, I examine the ontology of the knowns and unknowns in the algebra practiced by Fermat and Descartes. The algebraic landscape of their time offered two basic alternatives: the traditional numerical algebra familiar to readers of such figures as Rafael Bombelli, Simon Stevin, and Christoph Clavius, and the new, geometrical algebra of François Viète and his followers. As the familiar story goes, Fermat and Descartes both built on the latter. To understand the nature of their algebraic terms and the rationale behind their choice, we should summarize the conceptual foundations of both kinds of algebra, especially because for each of them recent research has modified old views.

We begin with an overview of the numerical algebra that Europeans had acquired from the Arabic world. This premodern algebra was not simply an early version of

the numerical algebra that we currently teach. It was grounded in a corresponding premodern notion of number, so that the monomials, polynomials, and equations we find in Diophantus, Abū Kāmil, Cardano, and Clavius were conceived in a radically different way from their modern counterparts. Very briefly, the core of the difference lies with the fact that the powers of the unknown were kinds of number, and not values as they are today. Our x is the value of an unknown, while Clavius's cossic 2℘ is a kind of number distinct from other kinds (powers). Only with a coefficient, like 12℘, does it become a value. Consequently, coefficients held a different relationship to the powers, and polynomials were aggregations, free of arithmetical operations. The different notations devised for working out problems in premodern algebra across all languages also reflect this conception, so that reading it as if it were some version of modern notation distorts its meaning.

Next we review Viète's *algebra nova*, where knowns and unknowns, instead, are values deriving from geometry. More precisely, they are the non-arithmetized measures of magnitudes, possessing dimension but unfettered by the limitation to line, surface, and solid, and equations between them arise out of ratio and proportion. They are not, as many historians since Jacob Klein have maintained, uninterpreted symbols that transcend number and magnitude. Viète's program was to develop propositions in geometry modeled on those in Euclid and other classical Greek authors, that is, in geometry without numerical measure, to serve as foundations for calculating the entries in astronomical tables. Ptolemy, after all, had based the calculations for his tables in Euclidean geometry, and Viète wished to respect this tradition. But Viète diverged from astronomers in the Ptolemaic tradition by reworking the "computational geometry" of the Greeks into a new algebra that would greatly facilitate calculation. Because his end goal was to use the geometric models for numerical calculation, he had no reason to restrict himself to three geometric dimensions – not just in his algebra, but even in his geometry. Instead of justifying these higher dimensions, he explained how they are useful. Not surprisingly, the notation Viète devised for his *logistice speciosa*, as he called his new algebra, is also a radical departure from that of contemporary algebraists.

When we finally turn to Fermat and Descartes, we find that in practice they both worked with the same non-arithmetized geometrical algebra as Viète, again with no justification for the higher-dimensional magnitudes that come with it. Fermat adopted Viète's system without modification, and even kept the same notation. And although Descartes began his 1637 *La Geometrie* by describing an algebra of line segments that bypasses the problem of dimensionality, he did not apply it in his algebraic solutions to problems. Instead, he worked in the same non-arithmetized algebra as Viète and Fermat, in which the dimensions of the terms must be taken into account.

Last, we inquire what led Fermat and Descartes to choose Vietan algebra over premodern, cossic algebra. Two obstacles in particular prevented the latter option from being chosen. The most obvious is that it is a numerical art, while Fermat and Descartes worked in geometry. But even if the terms could have been reinterpreted geometrically, there was no natural way that premodern algebra could have been modified to accommodate undetermined knowns, which are necessary for the

general solutions that Fermat and Descartes sought. The cause of this limitation lies with the conceptual foundation of premodern algebra in kinds, not values, and this foundation also made premodern algebra ill-equipped for other applications outside problem-solving. It was the shift from types to values, not the shift to abstract magnitudes, that allowed algebra to begin its path of overrunning the rest of mathematics.

2 Premodern Monomials, Polynomials, and Equations

European algebra in the time of Viète can be traced back via Italian and Latin texts to medieval Arabic algebra, and although we lack a textual connection, there is clearly a historical link between Arabic algebra and the algebra practiced in the *Arithmetica* of Diophantus of Alexandria (ca. third century CE) (Christianidis and Oaks 2013). It is the seemingly minor yet consistent differences in practice, wording, and notation between pre-Vietan algebra and our own elementary algebra that testify to a different way of conceiving of monomials, polynomials, and equations. Because my aim in this section is to provide a backdrop for comparison with the algebra of Viète, Fermat, and Descartes, I will describe the main features of premodern algebra using examples leaning toward their time. Many will be taken from Michael Stifel's 1544 *Arithmetica Integra*, though just about any other sixteenth-century text could have been chosen. Stifel's cossic notation was about as standard as one could find at the time, and it was the notation later adopted by Christoph Clavius, whose 1608 *Algebra* was studied by Descartes.

Stifel's notation uses the standard cossic signs that had been common among German algebraists since the previous century. The names given to the powers of the unknown in this system were adapted from Latin terms which were themselves ultimately translations of the corresponding terms in Arabic. In the cossic system, the first degree unknown is called a *radix*, the Latin word for "root," which was translated from the Arabic first-degree term *jidhr* ("root"). In notation its sign is ʓ. The square of a *radix* is called a *zensus*, deriving from the Latin *census*, translated from *māl*, the name of the second degree unknown in Arabic. Like the Latin *census*, the common meaning of *māl* is "sum of money" or "wealth." The cossic sign for a *zensus* is ʒ. The cube of a *radix* is called a *cubus*, the Latin word translated from the Arabic *kaʿb* ("cube"), and its sign is ƈ. And just as in pre-Renaissance algebra, most higher powers are named with combinations of the terms for the second and third powers. The fourth power was called a *zensizensus*, which ultimately comes from the Arabic *māl māl*, and its sign is ʒʒ. The European powers diverge from the Arabic after this point. Stifel's fifth power is called a *surdesolidus* (ß), his sixth is a *zensicubus* (ʒƈ), and higher powers follow without limit. The constant term in a polynomial, or what we call the zero-degree term, is called a *numerus*, and in Arabic, these numbers are usually counted in dirhams, a denomination of silver coin. Because algebra before Viète was founded in arithmetic, Stifel's unknown *radix* is always found to be a number, and numbers in arithmetic from the earliest Arabic texts can take on any positive value, including fractions and irrational roots.

In arithmetic, the cossic sign for square root is √ȝ, for cube root √cȝ, etc., so that for instance $\sqrt{72}$ was shown as √ȝ72.

In notation, this cossic algebra can look deceivingly modern. Take for example this polynomial from Stifel's book (1544, f. 238b):

It is tempting to read this as being identical to $12x^4 + 16x^3 - 36x^2 - 32x + 24$ and indeed if one follows Stifel's calculations the modern reading makes sense. But there are many indications in the book that he is not thinking like a modern mathematician and these differences are shared with algebraists all the way back to al-Khwārazmī and still farther back to Diophantus

Before turning to the premodern arithmetical foundation of algebra, I will mention two differences between Stifel's notation and ours. One is that when there is one of a term, he always writes the "1." So where we write $x^2 + 8x$, Stifel shows "1ȝ + 8ȝȝ" (1544, f. 277b.2), or where we write $x + \sqrt{205 - x^2}$ Stifel has "1ȝȝ + √ȝ.205 − 1ȝ." (the periods serve as parentheses) (1544, f. 281a.5). This inclusion of the "1" is present in every premodern notation from Diophantus to Arabic algebra to Latin, Italian, and the various notations in Renaissance Europe. Where we would write simply x, Scheubel (1550) wrote "1 ra.", Bombelli (1572) "1 $\overset{1}{\smile}$," Stevin (1585) "1 ①," and de Billy (1643) "1R" (Oaks 2017).

Another difference is that with a few exceptions beginning in Stifel's century, premodern algebraists insisted on keeping their coefficients rational. For example, Stifel writes in one place, "I multiply √ȝ $501\frac{9}{11}$ by √1ȝȝ, or √ȝ1ȝ, which makes √ȝ $501\frac{9}{11}$ ȝ." ("√ȝ $501\frac{9}{11}$ multiplico per 1ȝȝ, seu per √1ȝ, facit √ȝ $501\frac{9}{11}$ ȝ") (Stifel 1544, f. 292b.12). In modern notation, he multiplies $\sqrt{501\frac{9}{11}}$ by x to get $\sqrt{501\frac{9}{11}x^2}$, where we would write instead $\sqrt{501\frac{9}{11}}x$. In another instance he writes "I then multiply 1ȝȝ by √ȝȝ864 − 1ȝȝ, which makes √ȝȝ864ȝȝ − ȝ.") ("Multiplico igitur 1ȝȝ in √ȝȝ 864 – 1ȝȝ, facit √ȝȝ864ȝȝ − 1ȝ.") (Stifel 1544, f. 288a.2). In modern notation, he multiplies x by $\sqrt[4]{864} - x$ to get $\sqrt[4]{864x^4} - x^2$, again keeping the power under the root. Algebraists starting with the earliest extant Arabic texts in the ninth century similarly ensured that their coefficients remained rational by taking the root of the coefficient *and* the power (Diophantus did not work with irrational numbers). We discuss the sixteenth-century exceptions in Sect. 3.2 below.

2.1 Premodern Numbers, Premodern Polynomials

These curiosities, along with other consistent differences in the wording of certain steps and in the overall approach to problem-solving, are reflections of a different way of understanding the relationship between the coefficient and the power, and this relationship derives from the way that numbers themselves were conceived. Today mathematicians typically think of numbers as being elements of some abstract set equipped with the binary operations of addition and multiplication that satisfy the

ordered field axioms. Others might view numbers as being constructed from scratch, where zero is identified with the empty set. Many people with no university training in mathematics retain the idea that numbers are points on some imagined number line, or at least that the units in which one counts or measures (e.g., apples, pesos, meters, pounds) are not part of what constitutes a number.

Such was not the case with premodern numbers. I will first describe the setting in Arabic, from which European premodern algebra originated. (What I describe here applies also to numbers in ancient Greece (Klein 1968, 46ff; Mueller 1981, 59).) Numbers in Arabic, whether they arose in practical calculation or in the tradition of Aristotle and Euclid, were conceived as being numbers *of something*. A six was not simply a six, but must be six of some kind, like six geese, six men, six dirhams, six mithqals (a unit of weight) of gold, six sevenths ($\frac{6}{7}$, which in turn might be a number of some other unit, like mithqals), six degrees (6°), or six (abstract) units. In other words, numbers were not objects in themselves, but they necessarily modified – i.e., they counted or measured – a multitude of some material or intelligible unit. Some kinds of unit were divisible, such as units of weight and length, while others were indivisible, such as geese and the Euclidean unit. In an arithmetic book composed in 1301, the Moroccan polymath Ibn al-Bannāʾ wrote about the two aspects of a number, its "meaning" (*maʿnan*) and its "term" (*lafẓ*) (1994, 255.3). For "three men," the meaning is "three" and the term is "men." Of course, the term could be ignored when working out operations. And because numbers are amounts of some unit, they were necessarily positive, though sometimes "nothing" or "zero" entered into calculations.

Niccolò Tartaglia (1556, f. 2a-b), to pick a European example, frames these two aspects of number in Aristotelian terms while appealing to Euclid's definitions of "unit" and "number." Units, he tells us, come in two kinds, "Natural" ("*Naturale*") and "Mathematical" ("*Mathematico*"). "The Natural [unit] considers the things according to their being, as according to reason conjoined with some sensible material." ("Il Naturale considera le cose si secondo lesser, come secondo la ragione congionte con qualche materia sensibile" (Tartaglia 1556, f. 2a.29).) He gives many examples of Natural units, such as one gold ducat, one scudo, one fiorino (three denominations of currency), one yard of cloth, one pound of silk, one ounce of saffron, one pace, one yard, one degree, one minute (sexagesimal units), etc. Because they are rooted in the material world, such units are "infinitely divisible" ("divisibile in infinito"). "The Mathematical [unit], then, also considers the things conjoined, according to their being, with such sensible material (as with the Natural), but one takes them, or considers them as being abstracted from such sensible material according to reason." ("Il Mathematico poi considera le cose pur congiunte secondo lessere, con tal materia sensibile, (si come fa anchora il Naturale) Ma le piglia, over considera poi si come astratte, da tal materia sensibile secondo la ragione" (Tartaglia 1556, f. 2a.45).) Unlike Natural units, Mathematical units are indivisible ("indivisibile"). After covering these two kinds of unit, he turns to the definition of "number": "The number (as Euclid defined it in the second definition of the seventh [book]) is none other than a multitude composed of units," ("Il Numero (come diffinisse Euclide nella seconda diffinitione dil settimo) non è altro, che una

Moltitudine composta dalle unitade." (Tartaglia 1556, f. 2b.14).) where these units can be either Natural or Mathematical. As in Aristotle and in medieval Arabic, numbers in Tartaglia are always multitudes of some unit, whether that unit is sensible or noetic. Even if some sixteenth-century mathematicians may have advocated for a different meaning of "number," it is the common understanding exhibited in Ibn al-Bannāʾ and Tartaglia that informed the way algebraic monomials were conceived.

Premodern algebra was strictly an arithmetical art. As al-Khwārazmī wrote in the beginning of his seminal *Book of Algebra* (early ninth century), "When I considered what people need in calculation I found that it is always a number" ((al-Khwārazmī 2009, 97.1), my translation). Algebra could be used to solve problems in arithmetic, geometry, metrology, and even horology, as long as the parameters are given numerical measure. Algebra was not used, for instance, to find a geometric magnitude in itself, but only its numerical size.

The names of the powers in algebra are kinds of number in the same sense that geese, dirhams, and degrees are kinds of number. Again quoting al-Khwārazmī, "I found that the numbers which are necessary for calculation in algebra are of three kinds (*ḍurūb*), which are roots, *māl*s, and a simple number unrelated to a root or a *māl*." ((al-Khwārazmī 2009, 97.9), my translation. The plural of *māl* is *amwāl*, but we write it with the English suffix "s.") So in addition to men, degrees, and mithqals, we can also count or measure roots, *māl*s, and simple numbers. Al-Khwārazmī's algebraic terms "eight roots" (2009, 147.1) and "four ninths of a *māl*" (2009, 181.11) are multitudes of different kinds just as "eight men" and "four ninths of a mithqal" are multitudes of different kinds. (The modern versions of these monomials are $8x$ and $\frac{4}{9}x^2$.) Sixteenth-century algebraists likewise often called these algebraic kinds "numbers" or "quantities," like Tartaglia, who writes just before listing the names of the powers of the "different kinds of quantities considered in Algebra" ("diverse spetie de quantità, considerati in Algebra") (Tartaglia 1560, f. 1a). Just five examples of the kinds as "numbers" are Stifel (1544, f. 228a), Scheubel (1550, 1ff), Peletier (1554, 5), Gosselin (1577, f. 54a), and Clavius (1608, 7). The algebraic kinds, or powers, were also called by words meaning "name" or "denomination" in every language from Greek to European vernaculars (Oaks 2018, 269).

The premodern concept of number just described was formed without consideration of irrational roots, most likely before irrational numbers entered into calculations. Although irrational numbers are abundantly common in Arabic arithmetic and algebra, they did not participate in this idea of a number as a multitude. One can have three loaves of bread or two and a half loaves of bread, but it makes no sense to have $\sqrt{10}$ loaves of bread. For this reason, the "number," i.e., the coefficient, of a term in algebra was required to be rational. Stifel's $\sqrt{\text{ }501\frac{9}{11}\text{ }}\left(\sqrt{501\frac{9}{11}x^2}\right)$ is acceptable because $501\frac{9}{11}$, the number of *zensi*, is rational, while the whole term is acceptable as a potentially irrational number (Oaks 2017). Words meaning "number" from al-Khwārazmī to Clavius were used in more than one sense. The whole term "five cubes" ($5x^3$ in modern notation) could be called a "number," and at the same time the "number" of the term (5 in this example) meant its multitude.

Let us compare Stifel's term "16cc" from the polynomial shown above with its modern equivalent, $16x^3$. (The analysis would be no different if we were to choose in

place of Stifel's notation Cardano's "16 cu," Bombelli's "16$\overset{3}{\smile}$," or any other pre-Vietan version of this term.) In our $16x^3$, the 16 and the x^3 are both numbers, one known and the other unknown, that are understood to be multiplied together by the concatenation of their signs. But in Stifel's 16ƈɛ, as in the rhetorical "sixteen cubes," the "16" and the "ƈɛ" are two aspects of a single number, one telling the amount and the other the kind. It is like saying "16 bottles" or "16 euros." With regard to this last example, "euros" is a kind of currency, while "one euro" is a value or an amount. If in place of "1ȝ + 8²ɛ" Stifel had written "ȝ + 8²ɛ," it would have been read as "*zensi* and eight roots," which leaves unanswered how many *zensi* there are, much like "euros and 8 dollars" leaves unanswered the number of euros. This is why, whenever there is one of a term in premodern algebra, the coefficient of "1" is always written in notation. In modern algebra, we can write simply x^3 because the notation for the power already stands for a value. Here is another way of putting it: Imagine "sixteen euros" as a pile of sixteen one-euro coins. The "sixteen" and the "euros" are not two separate entities brought together to form the term, but are different aspects of a single amount. The same applies to Stifel's "16ƈɛ": the ƈɛ is the kind, and the 16 is how many there are. While we can today also interpret our monomials in this premodern manner, it only works for simple expressions. Reading modern notation as a number-kind pair breaks down when we stray just a little from simple monomials to terms like πr^2 or $3xy$.

The addition of algebraic terms works like the addition of other kinds of number, which helps shed light on how polynomials were conceived. Adding, say, two cubes to three cubes gives five cubes, but when the kinds (powers) are different, the conjunction "and" or some equivalent is used. Sibṭ al-Māridīnī (fifteenth c.) gives the example "if you add two dirhams to three things, the answer is two dirhams and three things" ("thing" (*shay'*) was another name for the first power in Arabic algebra). Written in our notation, this does not seem to do anything: $2 + 3x = 2 + 3x$. Unlike our equation, the Arabic is stated as an operation and its outcome: one *adds* the two terms *to get* the algebraic binomial "two dirhams and three things." And where our $2 + 3x$ is written with the sign for "plus," a word that functions as a quasi-preposition to indicate the arithmetical operation of addition, the Arabic "and" (*wa*) is simply the conjunction. There is no more addition in "two dirhams and three things" than there is in "two geese and three chickens."

Some algebraists compared the names of the powers to denominations of coins to help explain the addition of the different kinds. In Europe, these include Luca Pacioli (1494, f. 112a), Michael Stifel (1544, f. 231a), and Marco Aurel (1552, f. 71a). To add three ducats to two crowns, Aurel explains, "I cannot said that they are five ducats, nor five crowns: in reality they are three ducats and two crowns more, or two crowns and three ducats more. In this same way, I want to sum 3²ɛ with 2ȝ: I cannot say that they are 5²ɛ, nor 5ȝ: we are compelled to say that they are 3²ɛ and 2ȝ more, or 2ȝ and 3²ɛ more." (". . . no pueden dezir que son cinco ducados, ni menos cinco coronas: mas realmente pueden dezir que son tres ducados, y mas dos coronas, o dos coronas, y mas tres ducados. Assi mesmo quiero summar 3²ɛ, con 2ȝ: no podemos

dezir que son 5ce, ni 5g: mas forçadamente, diremos que son 3ce, y mas 2g: o 2g, y mas 3ce" (Aurel 1552, f. 71a).)

Unlike English, Arabic has a word that serves as the negative counterpart to "and." This word is *illā*, which I translate as "less," though outside mathematics "except" is usually better. For example, one can say "all the students except (*illā*) Joan." In arithmetic, the apotome that we write as $5 - \sqrt{3}$ is stated by Ibn al-Bannāʾ as "five less a root of three." (Ibn al-Bannāʾ 1994, 288.2), while he writes the corresponding binomial as "five and (*wa*) a root of three" (p. 287.21). As with the example sentence, the word *illā* indicates that what follows it is lacking from what precedes it. In algebra, the same "less" is used to state an amount in which one term has been removed from another term. Al-Karajī writes in one problem "If you cast away the thing from fourteen, it leaves fourteen less a thing" (Saidan 1986, 193.15). Like with the addition of different kinds, here the "fourteen less a thing" is the *result* of the operation. It is a deficient 14, specifically a 14 that is lacking a thing. The word *illā* does not mean the same as the English "minus," which, like "plus," is a quasi-preposition indicating the arithmetical operation. Incidentally, the word *al-jabr* ("restoration"), from which our word "algebra" originates, is used in the simplification of equations to "restore" such diminished amounts (Oaks and Alkhateeb 2007).

In Italian abacus texts of the fourteenth and fifteenth centuries, "less" was rendered as "*meno*" ("less"), while "and" became either "*et*/*e*" ("and") or "*più*" ("more"). The words *più* and *meno* correspond to the Latin *plus* and *minus*, where they also mean "more" and "less." (In my translation of the passage of Marco Aurel above, the "and two coronas more" is from "y mas dos coronas," where "y mas" is the Spanish version of the Latin "et plus," or the Italian "e più.") These two words appear in arithmetical and algebraic expressions in several sixteenth-century books where they also take the same meaning as the Arabic "and" and "less." In notation *plus* and *minus* are either abbreviated as "p̃" and "m̃," or they are shown with the signs "+" and "−". It is clear by the way authors before ca. 1600 described the terms and how they were applied in context that neither the Latin words nor the signs "+" and "−" were used in the modern sense. The words and the signs began to assume their modern meanings indicating the operations of addition and subtraction only with Viète (Oaks 2018, 253–4).

So Stifel's polynomial 12ggg + 16cc − 36g − 32ce + 24 is not a linear combination of the powers constructed from operations. It is a 12, a 16, and a 24 of three different kinds that have been diminished by a 36 and a 32 of two other kinds. The signs ce, g, cc, and ggg represent kinds, not values like our powers of x, and the terms are joined together like we join any collection of multitudes of different kinds. (Stifel does not have a sign for units, though other cossic algebraists did.) There is no scalar multiplication, no addition, and no subtraction intended in the notation. Said another way, the polynomial is an aggregation, or a kind of inventory, listing how many of each kind are present, and how many are lacking. It is thus fundamentally different from our $12x^4 + 16x^3 - 36x^2 - 32x + 24$.

Premodern polynomials were not thought of as functions or as elements of some abstract ring. They were ways of expressing unknown numbers using the same kind of language for saying known numbers. In Arabic one said "a hundred and seven and

forty" (147), the same way one said "a *māl* and forty-nine dirhams and fourteen things" (in modern notation, $x^2 + 49 + 14x$). (The number and the polynomial are from (Abū Kāmil 2012, 449.9, 451.14).) Several Arabic algebraists called polynomials "composite numbers" to distinguish them from monomials, or "simple numbers." In the sixteenth century polynomials were often referred to by terms like "quantities" or "cossic numbers." Caspar Peucer writes about three kinds of cossic number (*numerorum cossicorum*): simple (like 20ϩ, 24ϧ, and 30ⲥϩ), composite (like 1ϩ +12, 1ϧ + 1ϩ, and 2ϧ + 8), and diminished (like 2ϩ − 8 and 4ϧ − 6ϩ) (Peucer 1556, f. Mviija). Then, on the next page, he gives the example of the "number" (*numerum*), 12ϧϧ + 16ⲥϩ − 36ϧ − 32ϩ + 24, which he borrowed from Stifel.

Algebraic equations ideally expressed the equality of two cossic numbers, without any unresolved operations hanging over them. Jacques Peletier compared a two-term equation with an "equation" in currency (he writes "ç" for "ϧ," and "ℝ" for "ϩ"):

> Thus, an equation is an equality of value between numbers denominated differently, such as when we say, 1 écu is worth 46 sous: it is an equation between 1, with its denomination of écu, and 46, with its denomination of sous. So when we say, 1ç, equal to 4ℝ, it is an equation between 1 with its denomination of ç, and 4 with its denomination of ℝ.
>
> ("Equacion donq, ét une equalite de valeur, antre nombres diversemant denommez. Comme quand nous disons, 1 Ecu valoèr 46 Souz: il y à Equacion antre 1 avec sa denominacion d'Ecu: e 46 avec sa denominacion de Souz. Einsi, quand nous disons, 1ç, egal a 4ℝ: il y à Equacion antre 1, avec sa denominacion de ç: e 4 avec sa denominacion de ℝ" (Peletier 1554, 22).)

Because equations state the equality of numbers, however, represented, premodern algebraists routinely worked out all operations before stating equations. Thus, all equations should be polynomial equations, free of any unresolved operations. Four articles that deal with this topic for Arabic, Italian, Greek, and Renaissance European algebra, respectively are Oaks (2009), Oaks (2010), Christianidis and Oaks (2013), and Oaks (2017).

3 Modifications to Premodern Algebra

3.1 Divisions and Roots in Equations

Adding, subtracting, and multiplying polynomials results in another polynomial, but this does not hold for division and taking roots. When confronted with division by a polynomial, Arabic algebraists usually found some way of reasoning through the operations to construct expressions without unresolved divisions. The simplest way was to preemptively multiply all terms that would eventually form the equation by the divisor. Abū Kāmil was particularly adept at finding other ways around divisions, sometimes applying arithmetical identities, and sometimes giving names to the results of divisions and forming equations using them along with the names of the

powers. Two names he and other algebraists gave are *dīnār* and a *fals*, which are denominations of gold and copper coin. In one problem, for example, he writes: "we divide a thing by ten less a thing, so it results in a *dīnār*, and we divide ten less a thing by a thing, so it results in a *fals*" (Abū Kāmil 2012, 397.2). He then works with these names along with dirhams, things, and *māl*s, until multiplications can be performed to eliminate them. But some authors, notably al-Karajī, occasionally worked with terms of the form "A divided by B" in equations until the appropriate multiplications could be performed to cancel the division. Treating a phrase like "a thing divided by ten less a thing" (like our $\frac{x}{10-x}$) as if it were a term in a polynomial violated the idea that expressions should be free of operations, but it also made the solutions to many problems much simpler (Oaks 2009).

Resorting to terms of the form "A divided by B" never became common in Arabic algebra. But in medieval Italian abacus books, divisions occur more frequently because they were written in rhetorical solutions with the division bar, along with Arabic numerals, as in this example from Maestro Biagio as related by Benedetto da Firenze (1463): "$\frac{180 \text{ chose e } 120}{1 \text{ censo } 3 \text{ chose}}$, e questo è iguali a 10." (In modern notation, $\frac{180x+120}{x^2+3x} = 10$ (Biagio 1983, 117.7).) Divisions continued to be common in sixteenth-century Europe, still with the division bar. A simple example in Michael Stifel is "Aequantur igitur $\frac{10}{1+1\text{2}\text{ℓ}}$ & 7, facit $1\text{2}\text{ℓ}.\ \frac{3}{7}$" (f. 266b) ("Equating, then, $\frac{10}{1+1\text{2}\text{ℓ}}$ and 7, makes $1\text{2}\text{ℓ}\ \frac{3}{7}$").

Roots were treated similarly. As mentioned above, irrational roots did not fit the premodern way of conceiving of numbers as multitudes, yet they became an integral part of arithmetic anyway. Similarly, roots of monomials and polynomials were accepted in algebra.

The introduction of divisions and roots to equations did not open the door for other operations. This is true for addition and subtraction, but it is most evident for multiplication. No premodern text will admit an unresolved multiplication, such as "a root multiplied by ten less a root," to an equation, since multiplications can always be performed beforehand. The two sides of an equation remained ideally polynomials, even if they may have become compromised in some solutions with divisions and roots.

3.2 Irrational Coefficients

Before ca. 1500, notation was primarily a tool for working out problems. To communicate this work in a book or to explain the general rules, a rhetorical version, sometimes with a little notation included, was composed. As long as the notation was somehow tied to speech, it had to make sense, so irrational coefficients were forbidden. After 1500, we find notation in books becoming increasingly independent of the spoken word. An early example is Christoff Rudolff's 1525 *Coss*, where algebraic calculations are presented without the intervention of any verbalization of the equations. Rudolff was the first of a small group of algebraists of his century who saw an advantage in allowing irrational coefficients in notation. Rudolff used them hesitatingly, then they become more common in Girolamo Cardano (1539), Johann

Scheubel (1550), Rafael Bombelli (1572), and Simon Stevin (1585), with some others following suit through copying these authors. But many more algebraists continued to respect the semantics of the expressions by not allowing for irrational coefficients, including Michael Stifel (1544) (who criticized Rudolff's coefficients), Jacques Peletier (1554), and Niccolò Tartaglia (1560).

In the following century, irrational coefficients in premodern algebra became rarer. Benedetto Maghetti (1639) set off a controversy when he used them in his solutions, and authors like Christoph Clavius (1608), Jacques de Billy (1643), and Jacob R. Brasser (1663) followed tradition by ensuring that their coefficients remain rational. (See Oaks (2017, 161ff) for Maghetti's story. De Billy, for example, multiplies "1R − ℞5 − 3" by "℞5 + 3" to get "℞5Q + 3R − 14 − ℞180" (He writes R and Q in place of ²ℓ and ȝ, and ℞ for √). In modern notation, he multiplies $x - \sqrt{5} - 3$ by $\sqrt{5} + 3$ to get $\sqrt{5x^2} + 3x - 14 - \sqrt{180}$ (De Billy 1643, 269). Brasser, for example, squares "√1920–1²ℓ" (our $\sqrt{1920} - x$) to get "1920 − √7680ȝ + 1ȝ" ($1920 - \sqrt{7680x^2} + x^2$) (Brasser 1663, 301.11).) Like the introduction of divisions to equations, the admission of irrational coefficients by a handful of authors was not indicative of any conceptual shift. All other characteristics that identify a piece of text as being premodern are still present in these authors. The irrational "numbers" of terms stems from a convenient preference for notational syntax over rhetorical semantics. (See Oaks (2017) for a full discussion. There is one significant typographical error in the published version of the article. On page 154, line 19, the polynomial is shown incorrectly as "1ȝ + 2²ℓ + √2²ℓ." It should be "1ȝ + 2²ℓ + √2ȝ.")

3.3 Independent Unknowns

Different names for independent unknowns are attested already in the ninth century in Abū Kāmil's *Book of Birds*, and by the sixteenth century, several European algebraists were working with independent unknowns in conjunction with different notations to express them. Christoff Rudolff (1525), Girolamo Cardano (1539), Jacques Peletier (1554), and Simon Stevin (1585) are just some of the algebraists whose independent unknowns are discussed in Heeffer (2010). We review here the notation of Stifel's *Arithmetica Integra*, which was later adopted in the *Algebra* of Christoph Clavius.

Stifel introduces his unknowns on folio 251b. Recall that the signs for the powers of the (primary) unknown are ²ℓ, ȝ, cℓ, ȝȝ, etc. The powers of the second unknown are designated A²ℓ, Aȝ, Acℓ, Aȝȝ, etc., for the third unknown B²ℓ, Bȝ, Bcℓ, Bȝȝ, etc. He writes that one can simply write "A" for "A²ℓ," "B" for "B²ℓ," etc. To multiply powers of different unknowns, one concatenates the signs, so, for example, the product of 2cℓ by 4Aȝ is 8cℓAȝ. By this rule, 3Aȝ by 2²ℓ by 4Bȝȝ would be 24²ℓAȝBȝȝ: the signs for the unknowns are arranged in order from ²ℓ to A, B, etc. This is a notation for multiplying kinds, not values. The traditional cossic names already employed this idea, where for example ȝcℓ is the kind that results from multiplying *zensi* (ȝ) by cubes (cℓ). If Stifel meant the notation to be the

multiplication of values, then the result of 1q by 1A would be 1q1A instead of 1qA. Here "qA" is the kind that results from multiplying the kinds "q" and "A." Stifel, like other premodern algebraists, has no notation for the multiplication of values.

Simon Stevin also devised a notation for multiplying kinds. Where Stifel multiplied 3A by 2B to get 6AB, Stevin multiplies 3 *sec.*① by 2 *ter.*② to get 6 *sec.*① M *ter.*②. Here the kind "*sec.*①" is multiplied by the kind "*ter.*②" to get the new kind "*sec.*① M *ter.*②" (Stevin 1585, 259). Again, this is not the multiplication of values. The earliest use of concatenation for the multiplication of values I have found is in Vaulezard's 1630 translations of Viète's *Isagoge* and *Zeteticorum*. Concatenation appeared soon after in other algebraists, all of them indebted to Viète's new algebra.

4 François Viète's Geometrical Algebra

4.1 Preliminary Remarks on Viète

This section is condensed from my article (Oaks 2018), where I investigate the nature of Viète's species. In some places below I give the corresponding section of that article with a reference like "(§2.3)."

Below is a list of Viète's works cited in the present chapter. All were reprinted in his collected works, which were published in 1646 by Frans van Schooten, titled *Opera Mathematica*. After each title, I give the date of the original printing and the page number in the 1646 *Opera Mathematica*.

In Artem Analyticem Isagoge (1591, p. 1) (henceforth *Isagoge*)

Variorum de Rebus Mathematicis Responsorum, Liber VIII (1593, p. 347) (henceforth *Variorum*)

Effectionum Geometricarum Canonica Recensio (1593, p. 229) (henceforth *Effectionum Geometricarum*)

Zeteticorum (1593/1600, p. 42) (The first 16 folios were printed in Tours in 1593, and the remainder in Paris in 1600. Folio 16 ends in the middle of Zetetic IV.6 (Van Egmond 1985, 362))

Supplementum Geometriæ (1593, p. 240)

Ad Problema Quod omnibus Mathematicis totius orbis construendum proposuit Adrianus Romanus (1595, p. 305) (henceforth *Ad Problema*)

Pseudo-Mesolabum & Alia Quædam Adiuncta Capitula (consisting of the two works *Pseudo-Mesolabum* and *Adiuncta Quædam Capitula*. 1595, pp. 258, 275)

Ad Angularium Sectionum Analyticen (1615, p. 287)

De Æquationum Recognitione et Emendatione Tractatus Duo (consisting of the two works *De Recognitione Aequationum* and *De Æquationum Emendatione*. 1615, pp. 82, 127)

Ad Logisticem Speciosam, Notæ Priores (1631, p. 13) ((Freguglia 2008, p. 53) dates the composition to before 1593. I have not located any copy of the 1631 printing, so I refer only to the 1646 *Opera Mathematica*.)

J. Winfree Smith's English translation of Viète's *Isagoge* is printed in (Klein 1968), and T. Richard Witmer's English translations of several of Viète's works are published in (Viète 1983). I have taken or adapted translations of many passages

from these sources. Translations without a reference are mine. Sometimes I give Witmer's modern rendering of Viète's notation to clarify for the reader how that notation functions.

4.2 Overview of Viète's Program

There were two main currents in sixteenth-century mathematics, which were at once conflicting and entwined. One stemmed from the classical Greek texts of Euclid, Apollonius, Nicomachus, and others, in which the arithmetical unit is indivisible and geometric magnitudes are free of numerical measure. The other was the practical arithmetic, algebra, and geometry that was known to have come from medieval Arabic, and which in fact traces back to earlier Old World cultures. Numbers in this current can be partitioned indefinitely and were routinely applied to lines, surfaces, and solids.

The main interest of François Viète lay with Ptolemaic astronomy, in which these two currents met but did not mingle. Hipparchus of Bithynia (active 147–127 BC) is credited with being the first astronomer to apply Greek geometrical models of planetary motion to observational data. The models are cast in the non-arithmetized geometry of Euclidean magnitudes, while the observations consist of numerical measurements often recorded using physical instruments and arranged in tables. Hipparchus's approach was adopted by Ptolemy (second century CE), whose authority guaranteed its continuation down to the early seventeenth century, when the models, based as they were in uniform circular motion, were made obsolete with the work of Johannes Kepler.

Viète was one of the last astronomers to work in this Greek tradition. From his first published book of 1579, covering geometric models and the trigonometric tables derived from them, to the draft on planetary astronomy that he was working on at his death in 1603, his mathematical interests lay squarely with Euclidean geometry in the service of astronomical calculation. His publications in the intervening years deal directly or indirectly with the geometry and arithmetical calculations that underlie Ptolemaic astronomy, including his theorems on triangles, continued proportions, angular sections, and the numerical solutions to equations. Throughout these works, Viète remained faithful to the style and precepts of Greek authors.

One Greek work particularly influential for Viète's approach was Pappus of Alexandria's *Collection*, which was finally published in Commandino's Latin translation in 1588. Book VII covers the "domain of analysis," a topic that is barely touched on in other extant Greek works. In it, Pappus lists several books on, or important for, analysis by different Greek authors, and he describes their contents, including some of the propositions they contained (Pappus 1986, 66ff, 84). Most of these books are lost, and Viète was perhaps the first to compose a restoration of one of them. Based on the description given by Pappus (1986, 90–94), he wrote his *Apollonius Gallus* as a reconstruction of the *Tangencies* (*Ἐπαφῶν*, sometimes translated as *On Contacts*) of Apollonius. But more importantly, Pappus's Book VII likely played a role in inspiring Viète to transform the geometrical equalities prevalent in Greek works into a geometrical algebra that parallels the numerical

algebra practiced in his time. He introduced his *logistice speciosa* in his 1591 *Isagoge*, and that book opens by situating the new algebra in the context of ancient analysis.

4.3 Viète's Magnitudes and Numbers

The letters that constitute the objects of Viète's algebra will not make sense until we first establish how he understood geometric magnitudes and numbers, and for that we need to begin with the views of his contemporaries. The term *magnitudo* in sixteenth-century mathematics meant any geometric magnitude of dimension 1, 2, or 3, to the exclusion of numbers, time, angles, and other quantities (§2.3). Greek authors stated and proved propositions about these magnitudes without recourse to numerical measure, and this is naturally respected in medieval and early modern translations. But commentators often assigned numbers to the magnitudes in diagrams to illustrate the relationships between them, and many of these numbers are fractions or irrational. For example, in his commentary to Proposition II.12 of Euclid's *Elements*, Federico Commandino makes line AC 16 and line AB 20, and then approximates $\sqrt{231}$, the length of line AD, as $15\frac{1}{5}$, and with that he finds the area of triangle ABD to be approximately $98\frac{4}{5}$. In his commentary to Proposition XIII.1 he keeps the irrational roots, measuring lines with numbers like $5-\sqrt{5}$ and $\sqrt{20}+2$ (Euclid 1572, ff. 34b, 230a). The numbers that these mathematicians assigned to magnitudes were not intended as absolute measures. Rather, they illustrate the relative sizes of the magnitudes in a diagram, much like the numbers 1, 2, and $\sqrt{3}$ that we assign to the sides of the 30°–60°–90° triangle (§3.7).

Viète respected the ancient tradition of stating and proving propositions in non-arithmetized geometry, and like his contemporaries, he often assigned numbers to the lines after finishing his proof to illustrate their relative sizes. His numbers, too, are sometimes shown as approximations and sometimes as irrational roots. Figure 1 shows two examples, the first from *Variorum* in which he characteristically approximates the lengths of sides not with fractions, but with large integers. He gives three different arithmetizations, where each side in turn is set to be 100,000 and the other sides are calculated from it (Viète 1593a, f. 42a; 1646, 420). In the second, from *Zeteticorum*, he shows the sides of a triangle as $\frac{153}{61}$, $\frac{158}{61}$, and $\sqrt{13}$ (the latter as "*l* 13," where "*l*" stands for *latus* (side)) (1593c, f. 16a; 1646, 67) (§3.8).

In some settings in sixteenth-century mathematics, the word *numerus* took its discrete meaning after Aristotle and Euclid, so that numbers consist only of positive integers. In other settings, the word took its continuous meaning that was common in practical arithmetic, algebra, and astronomy, where numbers include fractions and irrational roots. In Viète's works, all numbers are regarded as being the measures of magnitudes, so they are of the latter, continuous type. The underlying context of all of Viète's mathematical works is geometry, and because there is no canonical geometric unit, the numbers with which he measures his lines express the sizes of the magnitudes relative to each other, like those in Commandino and other geometers (§3.8).

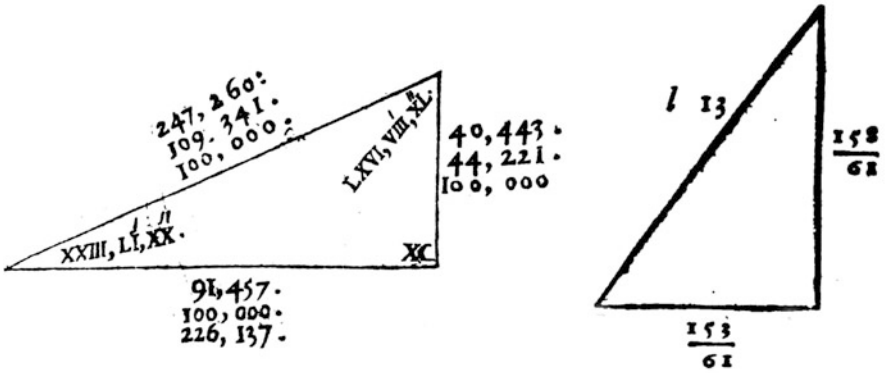

Fig. 1 Two of Viète's triangles, one showing approximations, the other fractions and an irrational square root

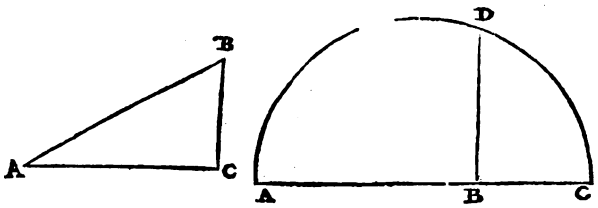

Fig. 2 The diagram for Viète's Proposition XIIII in *Effectionum Geometricarum*

One major way that Viète's geometry diverges from sixteenth-century practice is that he stepped beyond the third dimension. This occurs most clearly in Propositions XIIII and XV of *Effectionum Geometricarum* (1593), where he works with four-dimensional magnitudes based in the diagram shown in Fig. 2. He begins with right triangle ABC with right angle at C, and next to it he shows the same lines AB and BC laid out on a line that becomes the diameter if a semicircle. From the proportion $AB : BD :: BD : BC$, he gets $AB^2 : BD^2 :: BD^2 : BC^2$, and substituting $AC^2 + BC^2$ for AB^2, he arrives at $(AC^2 + BC^2) : BD^2 :: BD^2 : BC^2$. He then converts the proportion into an equality, first in *logistice speciosa*, and then again in terms of the magnitudes in the diagram, which gives $BC^4 + BC^2 \cdot AC^2 = BD^4$. This is expressed in purely geometric language and notation unrelated to any algebra:

> Quadrato-quadratum ex BC plus planoplano sub Quadrato ex AC & Quadrato ex BC aequetur Quadrato-quadrato ex BD. (Viète 1593b, f. 4b; 1646, 235)

He does not address the issue of the existence of these magnitudes, nor of the four-dimensional magnitudes in Proposition XV (§3.3).

In another direction, Viète found himself deriving relationships between magnitudes of arbitrarily high dimension in the setting of the trigonometry of multiple angles. He published his theorems on angular sections in two works: Chapter 10 of *Variorum* and Chapter 9 of *Ad Problema*. After Viète's death, Alexander Anderson added proofs and other theorems and published them in *Ad Angularium Sectionum*

Analyticen (1615). The main theorem on angular sections is in some sense a corollary of the corollary stated by Ptolemy to what is called Ptolemy's Theorem (Ptolemy 1998, 51ff). Converting Ptolemy's corollary from chords of arcs to sines and cosines, we can write it as:

$$\cos(a+b) = \cos(a)\cos(b) - \sin(a)\sin(b)$$
$$\sin(a+b) = \sin(a)\cos(b) + \cos(a)\sin(b).$$

Viète expressed these rules in terms of the ratios of the sides of right triangles, and by applying them repeatedly for angles $\theta + \theta$, $2\theta + \theta$, $3\theta + \theta$, etc., he derived rules for what we would write as $\cos(n\theta)$ and $\sin(n\theta)$ in terms of $\cos(\theta)$ and $\sin(\theta)$. These rules constitute Viète's main theorem, which is Theorem III in *Ad Problema* and *Ad Angularium Sectionum Analyticen*, and Theorem I in *Variorum*. In all three books, he first states the rules verbally, then in terms of *logistice speciosa*, and this is followed with several numerical examples. In *logistice speciosa*, he calls the hypotenuse of the single-angle triangle Z, the base D, and the height B. If we call the base of the triangle with angle $n\theta$ D_n, its altitude B_n, and its hypotenuse Z_n, then his proportions can be written as

$$D_2 : Z_2 :: D^2 - B^2 : Z^2$$
$$B_2 : Z_2 :: 2DB : Z^2$$
$$D_3 : Z_3 :: D^3 - 3DB^2 : Z^3$$
$$B_3 : Z_3 :: 3D^2B - B^3 : Z^3$$
$$D_4 : Z_4 :: D^4 - 6D^2B^2 + B^4 : Z^4$$
$$B_4 : Z_4 :: 4D^3B - 4DB^3 : Z^4$$
$$D_5 : Z_5 :: D^5 - 10D^3B^2 + 5DB^4 : Z^5$$
$$B_5 : Z_5 :: 5D^4B - 10D^2B^3 + B^5 : Z^5.$$

The rules for $D_2 : Z_2$ and $B_2 : Z_2$ are his versions of the rules for $\cos(a + b)$ and $\sin(a + b)$ shown above. Because the succeeding calculations are an easy corollary to those known rules, Viète does not give a proof or show a diagram. I drew the diagram in Fig. 3 to conform to the diagrams he shows for his numerical calculations. In the diagram, $Z = Z_n$, but this is not required in the theorems.

Here is how Viète states the theorem for the base of the quadruple angle triangle in all three books:

> In ratione quadruplâ, Hypotenusa secundi [Z_4] fit similis Quadrato-quadrato-Hypotenusæ primi [Z^4]. Basis [D_4], Quadrato-quadrato basis primi, minùs plano-plano sexies sub quadrato perpendiculi primi & quadrato basis eiusdem, plus quadrato-quadrato perpendiculi [$D^4 - 6B^2D^2 + B^4$]. (Viète 1593a, f. 15b; 1595a, f. 15b; 1615a, 12; 1646, 289, 316, 372)

The language here belongs to geometry, not to arithmetic or algebra. The meanings of the terms "*hypotenusa*" and "*basis*" are "hypotenuse" and "base," respectively, and "*plano-plano*" indicates a four-dimensional geometric magnitude just as it does in the example from *Effectionum Geometricarum* shown above.

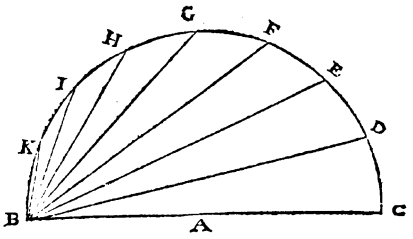

Fig. 4 Some numerical calculations with angular sections (Viète 1595, f. 11b; 1646, 319) Ad Problema

Figure 4 shows one of the sets of calculations that follow. Viète began by assigning the radius AC of a semicircle to be "100 000" and BD to be "196 000," from which he calculated BE through BK. Here, too, it is only the relative sizes of the numbers that matter. Viète's higher-dimensional magnitudes may have no perceptible existence, but the rules in which they appear give the correct proportions for the sides of triangles when converted to numbers (§3.5)

Just as Viète gave no explanation for his magnitudes in *Effectionum Geometricarum*, he gives none for these higher-dimensional magnitudes, either. But he does address magnitudes of dimension greater than three in points 26 and 27 of Chapter VIII in *Isagoge*:

> 26 Since all magnitudes are either lines or surfaces or solids, of what earthly use are proportions above triplicate or, at most, quadruplicate ratio except, perhaps, in sectioning angles, so that we may derive the angles of figures from their sides or the sides from their angles?
>
> 27 Hence the mystery of angular sections, perceived by no one up to the present either arithmetically or geometrically, is now clear, and shows
> How to find the ratio of the sides, given the ratio of the angles;
> How to construct one angle [in the same ratio] to another as one number is to another. ((Viète 1591, f. 9a; 1646, 12). Translation adapted from Viète (1983, 32).)

Instead of justifying the existence of higher dimensional magnitudes, Viète explains that they are *useful*, and the use to which he puts them is in numerical calculation.

Just as Ptolemy applied his version of the corollary to construct his table of chords, Alexander Anderson later remarked that Viète's theorems on angular sections can be applied to construct trigonometric tables in increments of $1'$ (Viète 1615, 47; 1646, 303–304) (§3.6).

To summarize, Viète's geometric magnitudes, like those of other mathematicians of his era, conform to classical Greek works in that they do not possess any inherent numerical size. But they are metrizable, and the numbers frequently assigned to them illustrate only their relative sizes, and not any absolute size. Viète parts from his contemporaries by freely admitting magnitudes of dimension greater than three. He gives no explanation of what kind of existence these magnitudes might have, but that would not have mattered to him because his interest lay with numerical computation. Viète's numbers are the continuous, practical numbers of the astronomers (and the algebraists) that include fractions and irrational roots, and their only purpose in his works lies with the measurements of geometric magnitudes. They have no independent existence.

In the sixteenth century, geometric magnitudes could be measured in two different ways. Classical Greek magnitudes are measured through ratio and proportion, and Viète and other Europeans of his time set up and manipulated ratios and proportions in their geometric propositions. But these same early modern European mathematicians also routinely assigned numerical measures to magnitudes, so one could also perform arithmetical calculations that parallel those non-arithmetized proportions. This gives magnitudes a dual nature when it comes to measurement, and these two ways correspond to the two algebras that Viète presents in his books.

4.4 Viète's Two Algebras

Viète called his new algebra *logistice speciosa* (specious logistic) to distinguish it from traditional numerical algebra, which he called *logistice numerosa* (numerical logistic). He borrowed the notation for the latter from Xylander's 1575 translation of Diophantus's *Arithmetica*. Translating the terms from Diophantus, Xylander called the first degree unknown a "Numerus," which he abbreviated as "N." The second degree is a "Quadratum," abbreviated as "Q," and the third degree is a "Cubus," abbreviated as "C." Higher powers, still translated from Diophantus, are "Quadrato-quadratum" (QQ), "Quadratocubus" (QC), and "Cubocubus" (CC). Here is an example equation in this notation from Viète's *De Emendatione Aequationum*: "30Q. − 156 N. − 1C., *æquatur* 440." ((1615b, 123.7; 1646, 155.30). The 1646 printing is identical except that it omits the periods.) Distorted into modern notation, it would be $30x^2 - 156x - x^3 = 440$. The recurring coefficient of 1, the absence of operations, and other features of *logistice numerosa* throughout Viète's works confirm that it belongs to the premodern algebra of the sixteenth century. And because all numbers in Viète are the measures of lines, planes, solids, etc., his *logistice numerosa* functions as an algebra for arithmetized geometry (§§4.1, 5.6).

Logistice speciosa, by contrast, is the algebra that Viète developed for geometry in which the knowns and unknowns are the relative sizes of the magnitudes themselves, and not numbers that measure them. This truly geometrical algebra was inspired in part by the computational geometry he read in Greek authors. Some propositions in Greek geometry concern spatial relationships of the magnitudes, while others specify only metrical relationships. (See, for example, Marie (1884, 4) and Panza (2006, 279).) In the latter case, it often happens that some of these magnitudes cannot exist in position. For example, Apollonius could write in proposition I.37 of his *Conics* that the rectangle contained by ΔZ, ZE is equal to the sum of the rectangle contained by ΔE, EZ and the square on ZE, even if no such rectangles can be drawn because the points Δ, Z, and E are colinear (Apollonius 1891, 112.5). Impossible magnitudes like these enter into the arguments only as (abstracted) sizes relative to other magnitudes deriving from the diagram. (Others, too, have made this observation, such as Mueller (1981, 42).) Moreover, the spatial relationships of some magnitudes are not relevant at all to the proposition, and in those cases they are drawn apart from the other magnitudes and are labeled with single letters. Euclid's Proposition VI.17, for example, deals with proportionality and shows four individual lines labeled A, B, Γ, and Δ. In other propositions, it is an area that is designated by a single letter, like regions Γ and Δ in *Elements* Proposition VI.29.

Viète reworked these geometrical equalities into an algebra, partly modeled on *logistice numerosa*. The knowns and unknowns cannot be based in any particular diagram showing spatial relationships, so he chose single capital letters to represent them, and he followed the order of the transliterated Greek alphabet, calling his "species" A, B, G, D, Z, etc. This notation would have made sense to mathematicians of the time, given the presence and purpose of single-letter magnitudes in Greek geometry (§§5.4–5).

Viète presented the outlines of his *logistice speciosa* in the short yet enigmatic 1591 book *In Artem Analyticem Isagoge* (*Introduction to the Analytic Art*). After three chapters covering preliminary stipulations and laws, he introduces the species:

On the rules of calculating with species. Chapter IIII.

Numerical logistic employs numbers, specious logistic employs species or signs for things, as, say, the letters of the alphabet. There are four basic rules for calculating with species just as there are for calculating with numbers.

RULE I.
To add a magnitude to a magnitude.

Let there be two magnitudes A and B. One is to be added to the other. ((Viète 1591, f. 5a; 1646, 4). Translation adapted from (Viète 1983, 17–18).)

Viète calls the species A, B, etc. of his algebra "magnitudes" (*magnitudines*) here and throughout his books. Unknown magnitudes are designated with vowels, and known magnitudes with consonants. These species, or magnitudes, can be raised to different powers, and these powers possess dimension. A simple "A," "B," "G," etc. is of the first dimension and is called a "side" (*latus*). (In rare cases when it does not

designate the measure of a line, it is called a "root" (*radix*), such as we see in Proposition LII in *Notæ Priores* (Viète 1646, 37).) The two-dimensional squares of these sides are called "A quadratm," "G quadratum," etc. Their cubes are called "A cubus," "G cubus," etc., their fourth powers, which are naturally four-dimensional, are "A quadrato-quadratum," "G quadrato-quadratum," etc., and higher powers continue to follow the pattern for the names in Xylander, translated from Diophantus: "quadrato-cubus," "cubo-cubus," "quadrato-quadrato-cubus," quadrato-cubo-cubus," etc. There is another series of terms used to label magnitudes whose lower-dimensional versions do not enter into the problem. A two-dimensional magnitude whose side does not appear is called "A planum," "B planum," etc. A three-dimensional magnitude is called "A solidum," "B solidum," etc., continuing with the four-dimensional "plano-planum," the five-dimensional "plano-solidum," etc., following the same pattern as the powers (§4.1).

The sample equation in *logistice numerosa* given above is a numerical version of this equation in *logistice speciosa*, here reproduced as shown in the 1615 printing (Viète 1615b, 122):

$$\left.\begin{array}{l} \text{B in A quad 3} \\ -\text{D plano in A} \\ -\text{A cubo.} \end{array}\right\} \text{æquetur} \left\{\begin{array}{l} \text{B cubo bis.} \\ -\text{D plano in B.} \end{array}\right.$$

In the 1646 *Opera Mathematica*, the same equation is written on one line: "B in A quadr. 3 − D plano in A − A cubo, æquetur B cubo 2 − D plano in B" (Viète 1646, 155.23). Witmer transforms it into more modern notation as $3BA^2 - D^PA - A^3 = 2B^3 - D^PB$ (Viète 1983, 303).

Certain features suggest that this notation should be read differently than the premodern notations we described earlier. First, a "1" is not written when there is only one of a term. In this equation, the "A cubo" has no coefficient that could count or measure the term, and this applies to every example in Viète's works. This means that the letters are not kinds, but values. Second, these values are sometimes multiplied together. In the first term, "B" is expressly multiplied by "A quad" by the presence of the preposition *in* ("by"). Similarly, "D plano in A" expresses the multiplication of the two-dimensional "D plano" by the one-dimensional "A." Perhaps the most noticeable difference is that known values are designated with letters and not numbers, which makes them provisionally undetermined. This feature has been cited as a great advance by historians dating back to Montucla's 1758 *Histoire des Mathematiques* (1758, 488). The "3" and the "bis" ("2"), on the other hand, function more like premodern "numbers" of terms to indicate how many of that term there are.

Proposition XVI of *Supplementum Geometriae* nicely illustrates the similarities and differences between three ways of comparing magnitudes. There a particular relationship is first written as a geometrical equality, then as an equation in species, and finally as a numerical equation. For the equality, A, B, C, and E are points in the diagram (Viète 1593d, f. 17b; 1646, 249):

> cubus ex AC minus triplo solido sub AC & quadrato ex AB, æqualis est solido sub CE & quadrato ex AB

For the equation in species, the unknown line AC is called A, and lines CE and AB are taken to be equal in length and are called Z:

> A cubus minus Z quadrato ter in A, æquetur Z cubo

For the numerical equation, Viète sets Z to be 1 and A to be 1N:

> 1C − 3N, æquatur 1

The equality is naturally stated using geometrical language, including the phrase we can translate as "triple the solid under CE & the square on AB." In the equation in species, the language of arithmetical operations is substituted, where this becomes "thrice Z squared [multiplied] by A."

We saw above how Viète produced proportions involving magnitudes of arbitrarily high dimension. It is by virtue of Viète's "supreme stipulation," in Chapter II of *Isagoge*, that these magnitudes can be freed from their ratios and enter into equations as independent objects:

> But the supreme stipulation of equations and proportions and which is all-important in analysis is:
>
> 15 If there be three or four magnitudes and the result of the multiplication of the extreme terms is equal to the result of the multiplication of the mean by itself or to the product of the means, then those magnitudes are proportional. And conversely,
>
> 16 If there be three or four magnitudes, and the first is to the second, so that second, or else some third, is to another, the product of the extremes will be equal to the product of the means.
>
> And so, a proportion can be called the composition (*constitutio*) of an equation, an equation the resolution (*resolutio*) of a proportion. (Translation adapted from Klein (1968, 324))

By this stipulation, the proportion $a : b :: c : d$ is equivalent to the equality $ad = bc$. It generalizes Euclid's *Elements* Propositions VI.16 and XI.34 by removing any restriction on the dimension of the terms in the equality. It is what allowed Viète to resolve the proportion in Proposition XIIII from *Effectionum Geometricarum* into a geometric equality with four-dimensional magnitudes.

In numerical logistic, one can add 1Q to 3N to get 1Q + 3N because numbers are homogeneous. But in geometry, magnitudes of different dimension are heterogeneous, so one cannot add, say, A quadratum to A. Viète solved this problem by multiplying the lower degree terms by known magnitudes of such dimension that all terms become homogeneous. For some given B, one can add "A quadratum" to "B in A" because they are both now two-dimensional. Thus his "Law of Homogeneity,"

laid out in Chapter III of *Isagoge*, states that only terms of the same dimension (power) can be added or subtracted.

Specious logistic was designed for solving problems in geometry. Given magnitudes are named with consonants, an unknown is named with a vowel, and then an equation or proportion is set up in terms of these species and simplified. The resulting equation or proportion can then be read as a formula from which one can either perform a geometric construction to show the unknown magnitude, or numbers can be assigned to the givens and the unknown can be calculated numerically (Viète 1591, f. 8a; 1646, 10). These two ways of exhibiting the solution are a reflection of the dual nature of geometric magnitudes. In his *Zeteticorum*, Viète solves 82 problems with his new algebra, giving only numerical solutions. Two of his successors, Jean-Louis Vaulezard and Marino Ghetaldi, later took up the task of producing answers by means of geometrical construction (Ghetaldi 1630; Viète 1630).

4.5 Summary of Viète's *logistice speciosa*

In creating an algebra for the non-arithmetized sizes of geometric magnitudes, Viète caused a radical reconception of polynomials, and of algebraic expressions in general. Now coefficients (knowns) and unknowns are both distinct objects of the same kind – measures of geometric magnitudes – that are necessarily multiplied together. And because monomials in *logistice speciosa* are now often stated with multiplications, and the final equation or proportion in a solution serves as instructions for either performing a geometrical construction or an arithmetical calculation, the signs "+" and "−" should be reinterpreted as operations, too.

Given quantities can only be undetermined in such a system. While one can name specific numbers, like 6 or $4\frac{4}{5}$, one cannot name the measure of a specific magnitude that is distinct from other magnitudes. Thus, given magnitudes are necessarily undetermined and are shown as consonants. The simplified equation or proportion obtained in solving a problem now conveniently becomes a formula stated in terms of the givens, so one can see precisely how the solution is obtained from the original parameters.

Two other features of this geometrical algebra differentiate it from numerical algebra. Because there is no canonical unit, all terms possess dimension, and this dimension must be respected when forming expressions. One can add and subtract only homogeneous terms, and multiplication results in a term of higher dimension than the multipliers. Because of this, the minimum dimension of a term is 1, so there can be no zero degree terms or reciprocals of terms as there are in numerical algebra. Division is thus possible only of a higher degree term by a lower degree term, as Viète tells us in Chapter IIII, Rule IIII in *Isagoge* (Viète 1591, f. 6a; 1646, 6). (Thus the expression shown in (Klein 1936, 180; 1968, 173) is Klein's fabrication, since it is a third degree term divided by a third degree term). Also, roots must have positive

integer degree. While Abū Kāmil could write "a root of three cubes" (in modern notation, $\sqrt{3x^3}$) (2012, 449.8), Viète could not take the square root of "A cubus 3" because the dimension would be fractional.

The letters of Viète's algebra are not symbolic entities that transcend arithmetic and geometry, as Jacob Klein argued (1936, 1968). Klein read Viète's rules for operating on the species in Chapter IIII of *Isagoge* as being axioms governing the relationships between the species. These rules, according to Klein, are general enough to cover both arithmetical and geometrical calculation, so that the species A, B quad., etc. in an algebraic expression can represent either numbers or magnitudes. The species themselves "are, therefore, comprehensible only within the language of *symbolic formalism*" (Klein (1968, 175), his emphasis). By this view, one can solve either arithmetic or geometry problems by translating the knowns and unknowns into *logistice speciosa*, and once the equation or proportion has been simplified, the solution can be found by reinterpreting the letters in terms of the original numbers or magnitudes.

Klein was apparently unaware that Viète worked with higher dimensional geometric magnitudes, and he passed over the several passages in Viète's works that unequivocally associate the species with magnitudes and not with numbers. His error was taken up by many historians, including even Michael Mahoney, who writes that Viète's *logistice speciosa* "is, to use modern terms, a language of uninterpreted symbols" (1994, 39), and Henk Bos, who saw it as "a method of symbolic calculation concerning abstract magnitudes" (Bos 2001, 147). I address Klein's account more thoroughly in 2018, §§6.2–3.

While readers of Viète in the past century have had a difficult time understanding the nature of the species, his immediate successors seem to have had little problem. Viète is quite explicit that his letters are magnitudes, and contemporary geometers all understood that magnitudes can enter into calculations via ratio and proportion, and they can also be assigned numerical values. It is not the species, but magnitudes themselves that can be measured in two ways.

5 Fermat's Algebra

5.1 Fermat, Student of Viète

When Pierre de Fermat (ca. 1607–1665) was in his early 20s, he traveled to Bordeaux, where he met students of Viète and studied Viète's works. As Mahoney observes, Viète "shaped Fermat's mathematical career as decisively as if the two men had stood in a living master-student relationship," and that "everything that Fermat did in mathematics, however original, bears Viète's imprint" (Mahoney 1994, 26). In Bordeaux, Fermat quickly and wholeheartedly embraced Viète's new algebra, which, like Viète, he saw as a tool with which to restore the analysis practiced by ancient geometers. Fermat appropriated precisely Viète's notation, too, which he

continued to use to the end of his career even after the notation of Descartes had eclipsed it. This notation is already the main tool of analysis in Fermat's *Method for Determining Maxima and Minima and Tangents to Curved Lines*, completed by 1629. (*Methodus ad Disquirendam Maximam et Minimam*, published in Fermat (1891, 133–179). The title and its translation are taken from Mahoney (1994, 55).) For example, to solve the problem of finding the cone of maximum surface that can be inscribed in a given sphere, he draws the semicircle shown in Fig. 5, calling line AB *B* and line BC *A*. (Following the edition of his works (Fermat 1891), we write Fermat's species in italic font, and points in diagrams in regular font.) From there, he determines that he needs to maximize the fourth-degree amount "*B* cub. in *A* + *B* quad. in *A* quad. − *B* in *A* cub. − *A* quad.quad." (Fermat 1891, 157).

It is also with this algebra that Fermat developed his analytic geometry . Like Viète, he undertook the restoration of a lost work of Apollonius described by Pappus in Book VII of the *Collection*. Fermat chose Apollonius's *Plane Loci*, and it was during his struggle to prove Proposition II.5 of his restoration, and through his subsequent investigations of loci generally, that he hit upon the idea of transforming the *symptômata* of conic sections, that is, geometrical equalities that characterize the curves, into Vietan equations in two unknowns (Mahoney 1994, 112ff). Fermat completed his restoration of *Plane Loci* around 1635, and the following year he outlined a classification of equations and their corresponding curves in *Introduction to Plane and Solid Loci*. (*Ad Locos Planos et Solidos Isagoge*, published in Fermat (1891, 91–110).)

Where Viète had been concerned with developing geometrical models for astronomical calculation, Fermat's focus was on the geometry itself. So unlike Viète, Fermat never assigns numerical measures to the species, and in work after work he relates the algebraic expressions and equations to the magnitudes in geometric diagrams.

5.2 Fermat's Interpretation of the Species

With about four decades separating them, and given their different interests, we might wonder if Fermat interpreted the species differently than their creator did. Reading over Fermat's works, one finds that he rigorously observed the law of homogeneity and that he followed Viète in working with magnitudes of arbitrarily high dimension. At least for the mechanics of the algebra, there is no indication that Fermat's understanding of the species diverged from that of Viète. Mahoney, however, argued that Fermat viewed his algebraic terms as all being homogeneous:

> Although Fermat paid lip service to Viète's Law of Homogeneity, his use of algebra in geometric situations clearly shows that he no longer attached dimension to the degree of an expression. Fermat operated as if all combinatory operations on geometrical magnitudes yielded homogeneous products. At no time, however, does he justify his behavior. (Mahoney 1994, 42)

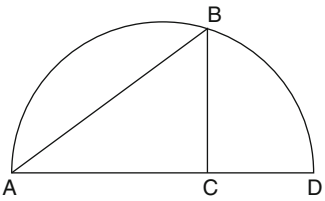

Fig. 5 From Fermat (1891, 156)

Mahoney came to this conclusion based in part on this claim:

> . . .every equation of Viète's analytic art had dimension, and the dimension was directly linked to the degree of the equation. For example, the solution of a cubic equation corresponded to a solid construction in three-dimensional space . . . (Mahoney 1994, 42)

Viète never solves a problem in his *Zeteticorum* with a geometrical construction, so such solutions to equations will not be found among his worked-out problems. But he does give the constructions necessary for solving particular problems in two other works: *Effectionum Geometricarum*, which covers basic ruler-and-compass constructions, and *Supplementum Geometriae*, which covers propositions on the trisection of an angle. In 7 of the 45 propositions presented in these 2 books, Viète states algebraic equations that can be solved by the given construction, and of those 7, the degree of the equations in 4 of them do not match the dimension of the construction. (Propositions IX, X, XI, XIIII, and XV in *Effectionum Geometricarum*, and Propositions XVI and XXIIII in *Supplementum Geometriae*. Only the first three in the first work show a match between degree and dimension.)

In the introduction to *Supplementum Geometriae*, Viète postulates a neusis construction: "To draw a straight line from any point to any two given lines, the intercept between these being any possible predefined distance" (Viète (1593, f. 13a; 1646, 240), translated in Bos (2001, 168)). In Proposition IX, he applies this construction to the problem of trisecting a given angle in the context of a two-dimensional diagram. Then, in Proposition XVI, with essentially the same diagram, he gives a third-degree algebraic equation that corresponds to that solution: "A cubus minus Z quadrato ter in A, æquetur Z cubo." Viète also arrives at cubic equations in Proposition XXIV, for the problem of inscribing a regular heptagon in a circle. In both propositions, the degree is 3 and the dimension is 2.

A similar situation arises in Propositions XIIII and XV in *Effectionum Geometricarum*. These are the propositions in which Viète works with four-dimensional magnitudes, discussed above in Sect. 4.3. The diagrams are again two-dimensional, and this time the equations are of the fourth degree. After showing the relationship between the lines as a proportion involving ratios of two-dimensional magnitudes, Viète gives a corollary showing the fourth-degree equation that this construction will solve. In Proposition XIIII, this is "A quadrato-quadratum, plus B quadrato in A quadratum, æquetur D quadrato-quadrato" (Viète 1593b, f. 5a). Given the equation, one can appeal to Theorem I in Chap. XII of *De*

Recognitione Æquationum to make a substitution that transforms it into a quadratic equation, whose solution is constructible (Viète 1615b, 27–28; 1646, 99; 1983, 191). The equation in Proposition XV can be similarly reduced to a quadratic equation by Theorem III in the same chapter. There is in fact no rule in Viète linking the degree of an equation with the dimension of the solution. We can only infer from the few examples in these two works that it is the dimension of the original problem that corresponds to the dimension of the solution.

Mahoney also misunderstood Viète's higher-dimensional magnitudes. To account for their geometrical meaning, Mahoney wrote: "their interpretation was possible, though it required the introduction of 'mechanical' procedures like the *Pseudo-Mesolabe* for generating fourth, fifth sixth, etc., proportionals to two given line segments" (Mahoney 1994, 42). This *Pseudo-Mesolabe*, described in Proposition II in Viète's *Pseudo-Mesolabum* (1595b, f. 2b; 1646, 259), serves specifically to produce four lines in continued proportion. The propositions that follow likewise all deal with exactly four lines. There is no mention of producing five or more lines in continued proportion, so the mechanical procedure only gives lines whose relationship can be expressed with a cubic equation. Nor is there mention in any other work of Viète's of a "mechanical" procedure to produce a series of five or more magnitudes in continued proportion (though Descartes later would do it with his Mesolabe (Descartes 1637, 317ff, 370)). Instead, Viète generates proportional series in terms of the higher powers of his species. Proportional series are introduced in Proposition II of *Notæ Priores* (1646, 13). Two magnitudes A and B are followed by "$\frac{B\ \ quadr.}{A}$," "$\frac{B\ \ cubus}{A\ \ quadr.}$," "$\frac{B\ \ quad.quadratum}{A\ \ cubo}$," etc. He finds the proportionals between two given magnitudes A and B in Proposition V (1646, 15), with the example of quintuplicate ratio. He first makes the series of five-dimensional species in which the extreme terms are "A quadrato-cubus" and "B quadrato-cubus." Witmer translates this series as A^5, A^4B, A^3B^2, A^2B^3, AB^4, B^5 (1983, 37). Viète then takes the fifth roots of each term so that the extreme magnitudes are A and B. In Viète, higher dimensional magnitudes are used to produce the continued proportions, not the other way around. As I explained in the previous section, Viète did not give any geometric meaning to his magnitudes of dimension greater than three. They arise naturally in the theorem on sectioning angles, and he worked with them because they were useful for numerical calculation.

With the misunderstandings that the degree of the equation corresponds to the dimension of the problem and that Viète's higher dimensions are artifices that are justified through proportional lines, Mahoney concluded that

> both Fermat and Descartes saw clearly the difficulties that Viète's translation of geometry into algebra caused if one tried to apply it to a realm of problems which themselves involved dimensionality, e.g. locus problems. If one wishes to determine the nature of a locus, which itself may be dimensionless or have a dimension depending on the conditions, one cannot use a vehicle of analysis that is already burdened by dimensionality. (Mahoney 1994, 42)

But when viewed against Viète's actual practice, there is nothing about his species that would prevent them from being employed to solve locus problems, and

consequently there is nothing in Fermat's writings to suggest that he held a different view of the species than Viète. But one should wonder, then, how Fermat understood higher-dimensional terms like the four-dimensional expression quoted above, or the terms in an equation like "*Aqq*. æquale *Zpl*. in *Aq*. − *Zs*. in *D*" from *Introduction to Plane and Solid Loci*. ((Fermat 1891, 109). Fermat abbreviates *quadratum*, *planum*, and *solidum* as *q*, *pl*, and *s*.) Characteristically, he does not offer an answer. All I can suggest is that like Viète, he saw higher-dimensional magnitudes in his intermediate calculations as useful, since they give the correct results when the simplified equations are interpreted in two- or three-dimensional space.

6 Descartes's Algebra

Descartes published his only mathematical treatise, *La Geometrie*, as the third appendix to his *Discourse on Method*. The book appeared in 1637, the same year that Fermat shared his *Introduction to Plane and Solid Loci* with the mathematicians in Paris (Mahoney 1994, 72). Descartes, like Fermat, was interested specifically in geometric problem-solving (Bos 1990; 2001, 229), and like Fermat, his analytic geometry was inspired at least in part by his solution to a locus problem originating in Book VII of Pappus's *Collection*. This problem had been proposed to him in 1631 by Jacobus Golius, a professor at University of Leiden, and Descartes had solved it by January of the following year (Bos 2001, 271). It asks for a point C such that lines extending from C to given lines and forming given angles with them make certain products equal (Sasaki 2003, 206; Bos 2001, 313ff; Pappus 1588, f. 165a; 1986 I, 120). The solutions to this indeterminate problem form a curve, and Descartes's solution to the general case of four lines, given in Books I and II of *La Geometrie*, illustrates his method of representing loci by equations in two unknowns. The method is equivalent to that of Fermat: one unknown is measured along a given line from a given point, and the other is measured at some angle from it. He sets up equations for other locus problems, too. One of these is the equation that describes the curve traced by what Bos calls the "turning ruler and moving curve" procedure (Bos 2001, 278), which Descartes employs later to trace the solutions to equations. He also forms an equation for the solution to a special case of the five-line Pappus problem, and algebraic expressions and equations are also instrumental in his solutions to the other problems in Book II, both for finding normal lines to curves and for constructing ovals satisfying particular optical properties. (The equations for the three loci are given at Descartes (1637, 322.5, 325.-1, 337.10).)

For his version of specious algebra, Descartes uses lowercase letters, usually with x and y as unknowns and other letters as knowns, and he shows multiplication by concatenation. He also introduces superscripts for exponents. What was "E cubo-cubus" in Viète becomes "y^6" in Descartes, though for the square he preferred yy to y^2. Here are two sample equations, the first one describing a curve traced by the turning ruler and moving curve procedure from Book II, and the second an example provided for a rule for manipulating equations from Book III (Descartes 1637, 322, 379):

$$yy = cy - \frac{cx}{b}y + ay - ac$$

$$x^3 - \sqrt{3}xx + \frac{26}{27}x - \frac{8}{27\sqrt{3}} = 0.$$

There was precedence for indicating multiplication by juxtaposing species. Jean-Louis Vaulezard did so in his 1630 French translations of Viète's works, and we find it also in the arithmetical versions of *logistice speciosa* in Thomas Harriot (1631), William Oughtred (1631), and James Hume (1636). These last three authors had no need for the law of homogeneity, since their species are now numbers. Harriot, for example, could write an equation like "$aaa - 127296. a = 85700000$" (Harriot 1631, 145), and Oughtred could divide "BA + A" by "A" to get "B + 1" (Oughtred 1631, 11).

In the beginning of his book, Descartes tells us how to interpret his letters. He famously outlines an algebra of line segments by "taking one line which I shall call unity in order to relate it as closely as possible to numbers, and which can in general be chosen arbitrarily . . .," and then redefining multiplication, division, and root extraction so that the outcome is always another line segment. For multiplication, "having given two other lines, to find a fourth line which shall be to one of the given lines as the other is to unity" (Descartes (1637, 297), translated in Descartes (1954, 2)). He defines division and square root similarly, and he gives ruler-and-compass constructions for these operations on the next page. As Henk Bos has stressed, "in Descartes' interpretation the algebraic operations as applied in geometry did not concern numbers but geometric magnitudes, namely, the segments. Although he did introduce a unit line segment, he did not identify line segments with their numerically expressed lengths." (Bos 2001, 296). By redefining multiplication, division, and square root, Descartes created an algebra of lines whose operations agree with the corresponding operations of numbers in practical algebra. With it he could make sense of powers greater than three, and he could add and subtract what would otherwise have been nonhomogeneous terms. (See Bos (2001, 293ff) for a discussion on Descartes's redefinitions of the operations.) He was thus free to work with equations like the second example shown above.

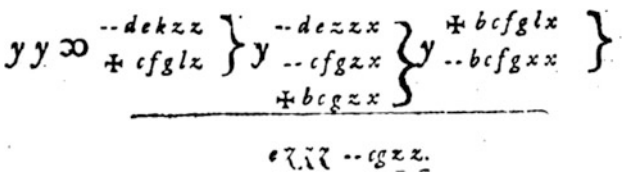
But with this apparent abandonment of homogeneity, it is important to consider what he writes next:

> It should be noted that all parts of a single line should always be expressed by the same number of dimensions, provided unity is not determined by the conditions of the problem. Thus, a^3 contains as many dimensions as abb or b^3, these being component parts of the line which I have called $\sqrt[3]{3a^3 - b^3 + abb}$. (Descartes (1637, 299), translated in Descartes (1954, 6).)

So if no unit is declared, then the operations of multiplication, division, and root extraction necessarily revert to their traditional geometrical meanings, and the law of homogeneity must be obeyed. Indeed, apart from one particular instance of the Pappus problem, no unit is posited in any problem posed in Book II. All expressions

and equations in those solutions are homogeneous, like the first equation shown above. This does not stop him from working with higher-degree equations, however. For example, one homogeneous equation in Book II is of the sixth degree, beginning "$y^6 - 2by^5 \ldots$" (Descartes 1637, 344).

The Pappus problem deserves special attention. Descartes also works with higher powers there, too, though his general equation is only of the second degree. He sets up this equation in unknowns x and y, and in known b, c, d, e, f, g, k, l, and a parameter z used in defining ratios:



In more modern format, it is this:

$$y^2 = \frac{(cfglz - dekz^2)y - (dez^2 + cfgz - bcgz)xy + bcfglx - bcfgx^2}{ez^3 - cgz^2}.$$

After making some simplifying assignments, he solves the equation for y in terms of x. From there, he gives detailed instructions on how to construct solutions, and he explains based on whether different givens are added, subtracted, or "nothing" (*nulle*) whether the locus of solutions is a line, circle, ellipse, parabola, or hyperbola. All this is done with homogeneous expressions without any declared unit. Then, after completing his description of the constructions of solutions, Descartes writes:

> And if one wants to show all the given quantities by numbers, by making, for example, EA = 3, AG = 5, AB = BR, BS = $\frac{1}{2}$BE, GB = BT, CD = $\frac{1}{2}$CR, CF = 2CS, CH = $\frac{2}{3}$CT, and that angle ABR be of 60 degrees, and finally that the rectangle of the two, CB, & CF, be equal to the rectangle of the two others CD & CH ... (Descartes 1637, 333; 1902, 405)

Making EA = 3 establishes the unit. Making AG = 5 is equivalent to saying that AG = $\frac{5}{3}$EA, and making angle ABR 60° serves to make EB = 2BS. It is from the last condition that the equation "$yy = 2y - xy + 5x - xx$" is established, which describes a circle (the axes are at a 60° angle). It was not necessary for the construction of the solution for Descartes to have assigned a unit. Had he written "AG = $\frac{5}{3}$EA" in place of "EA = 3, AG = 5," then since EA = k, the unitless, homogeneous equation would have been $yy = \frac{2}{3}ky - xy + \frac{5}{3}kx - xx$, and the construction of solutions would have been exactly the same. Descartes may have posited EA = 3 to illustrate his algebra of line segments, or perhaps to give meaning to the higher degree terms in the derivation of the general equation that preceded these assignments.

In Book III, where Descartes investigates the roots and transformations of equations and how to construct solutions, he usually works with examples of

heterogeneous equations for which some unit has been chosen. These examples are not given in the context of any particular problem, however. Bos has noted that Descartes works with these two interpretations of the operations, one from his algebra of line segments and the other from traditional geometry that takes into account dimension. Descartes himself does not address the issue of the compatibility of these interpretations, which suggests to Bos "a certain carelessness about the matter" (Bos 2001, 301). (Bos notes that they are in fact compatible, as one early commentator showed.)

Perhaps Descartes's statement that the unit "can in general be chosen arbitrarily" should be understood to mean that it is *potentially* present in problems where it is not declared. No unit is declared in the general solution to the Pappus problem, but afterward Descartes's choice of a unit for one particular arrangement of the lines can be interpreted as retroactively giving meaning to all the terms of degree greater than three in the general solution leading to that specific setup. But that is all it would do, because the selection of a unit is unnecessary for constructing such particular solutions. Further, Descartes does it for only one case of one problem. No other solution in Book II is followed by a solution "by numbers." We can infer, then, that Descartes preferred to find general solutions, after which a solution "by numbers" was merely an option. Because of this, he effectively worked in the same non-arithmetized geometry as Viète and Fermat. Every term in Descartes's expressions arising from general solutions have positive integer degree, and the law of homogeneity is observed. As in Viète, magnitudes in the problems solved by Descartes are without any intrinsic numerical measure, but one can later assign numbers to them for whatever purpose one has in mind.

There is one minor formal development in Descartes's notation for homogeneous expressions that may have been inspired by his geometry of line segments. Where Viète would have written $\frac{\text{B in A}}{\text{Z}}$, a dimension 2 term divided by a dimension 1 term, Descartes writes many homogeneous terms like $\frac{a}{z}x$ (1637, 328), where the letters are arranged so that it appears that the $\frac{a}{z}$ has some geometrical meaning by itself. But this way of writing, the term only functions as a notational device to separate the unknown x from the rest of the expression. The whole term is one-dimensional, like the corresponding term in Viète.

In solving problems in geometry, then, Descartes works with essentially the same algebra as Viète and Fermat. This is an algebra rooted in the non-arithmetized sizes of geometric magnitudes, which can, if one chooses, be given numerical measure (Fermat never takes this option, but it is prevalent in Viète). All terms have positive integer degree, only homogeneous terms can be added and subtracted, and powers greater than three are given no geometric meaning. Descartes's algebra of line segments, which appears to be a creative solution to the problem of magnitudes of higher dimension, comes into play only when numbers are assigned to lines. Such arithmetizations can help illustrate the general solutions or they may be applied to real-life problems, but they are not a necessary part of geometrical problem-solving.

7 Synthesis

One important, but ultimately inconsequential, difference between premodern algebra and Viète's *logistice speciosa* is that the unknowns of the former are numbers, while Viète's species belong to geometry. We have seen that Harriot, Oughtred, and Hume all reinterpreted the species as numbers, and in the other direction, numerical algebra could be applied to problems in classical geometry by positing a unit line, as al-Khayyām had already done in the eleventh century. What definitively differentiates premodern algebra from Viète's specious logistic is how expressions were conceived. Premodern algebra is based in multitudes of kinds of numbers and their aggregations, while Viète's algebra is based in values assembled via operations. We can ask, then, what advantage Viète's algebra had over premodern algebra for the work of Fermat and Descartes. How is it that they chose Viète's species, and could some version of premodern algebra have sufficed?

Descartes learned cossic algebra from Clavius's 1608 textbook, and it is that algebra that he employed from the late 1610s down to at least 1628 (Rabouin 2010). There was at least one time in this period that he could have benefitted from undetermined coefficients. In notes he took in 1619–1620 on cubic equations in relation to his mesolabe compass, he sometimes expressed a particular type of equation by putting a circle, or an "O," in place of the coefficients, such as an "equation between Oꝛꝛ & O²ꝛ + ON" ("aequationem inter Oꝛꝛ & O²ꝛ + ON" (Descartes 1908, 244)). We would write this in modern notation as an equation between ax^3 and $bx + c$. The fact that three copies of the same sign "O" stand in the places of three potentially different amounts indicates that they are more like circles in which one could fill in numbers than letters standing for undetermined values. Clavius expressed an equation type like this by simply not writing anything for the coefficients, like his generic equation "between ȝ + ꝛꝛ, & N" ("inter ȝ + ²ꝛ, & N" (Clavius 1608, 52.6)) for what we would write as an equation between $ax^2 + bx$ and c. This is a notational example of the rhetorical equation types that go back to al-Khwārazmī, who wrote this particular type as "[some] *māl*s and [some] roots equal a number" before giving the specific example "a *māl* and ten roots equal thirty-nine dirhams" ((al-Khwārazmī 2009, 101.2), my translation).

No premodern algebraist is known to have devised either words or notation for undetermined coefficients. One could suggest that Stifel or Stevin were on the verge of such a notation, because they could have regarded their independent unknowns as being given, so that our $ax^2 + bx = c$, for example, could have been written by Stifel as "1ȝA + 1²ꝛB equals 1C." But this construction would have been decidedly inconvenient, because the coefficients become embedded in the kinds, which obliterates the fundamental premodern distinction between the coefficient (i.e., the multitude) and the power (i.e., the kind). Multitudes and kinds cannot just be merged together into new, composite kinds that themselves are assigned a multitude. For one thing, one should be able to replace the letters with determinate numbers, but in this scheme that cannot happen without dismantling the types. I had suggested in Oaks (2018, 287) that independent unknowns could have served as undetermined givens, but now I see that it could not have worked.

Or one might wonder why they could not have just written something like "A𝒿 + B²𝓆 equals C," where A, B, and C now stand for the values of numbers such as we find in Book II of Pappus's *Collection* or in *De Numeris Datis* of Jordanus de Nemore (early thirteenth c.). Such letters as values were known in Stifel's time, though they served as labels in premodern arithmetic and are not found together with algebraic terms. If such a contrivance was ever considered, there would have been a problem as soon as there was a need to operate on the terms, since the letters, as labels, were not operated on to produce more complex expressions (§5.4). Xylander (1575) and Gosselin (1577) took small steps in introducing operations to letters that designate values, though they did not mix this notation with algebraic notation. Those steps might have eventually led to another modification of premodern algebra, but they came too late (Oaks 2018, §5.4).

With nine different known magnitudes in Descartes's general solution to the Pappus problem, it would have been impossible for him to have written the equation in cossic algebra even if he had reinterpreted the kinds as being magnitudes. Descartes is silent about when he first saw examples of *logistice speciosa*, but it was likely to have occurred between 1628, when Beeckman recorded samples of cossic algebra from Descartes's hand, and January 1632, when Descartes solved the Pappus problem, presumably with essentially the same algebra that he shows in *La Geometrie*. (Sasaki (2003, 235ff) reviews the evidence regarding when Descartes may have first become aware of Viète's algebra.)

It is no surprise that Fermat chose to adopt Viète's algebra and its notation, given that he studied both Viète and Pappus, and that he, too, sought to restore Greek analytic geometry. Numerical algebra would have held no appeal for him when he had at hand an algebra designed for the geometer. His work, too, necessarily required undetermined givens, so cossic algebra would have also been inadequate for him.

Premodern algebra had always been an excellent arithmetical technique for solving problems, but it was limited by the identification of expressions as numbers, which were by their nature amounts of some unit or units. Geometric magnitudes are not multitudes of units, so when Viète set about making an algebra for geometry, it was naturally based in values, and thus expressions were necessarily formed through operations, and givens could only be undetermined. These last two features of *logistice speciosa* were somehow accidental, but they offered critical advantages. We have seen that in Viète, solutions to equations in problem-solving become for the first time formulas expressed in terms of given parameters, and in Fermat and Descartes general locus problems and problems of finding tangent and normal lines, with unspecified givens, can be solved algebraically. These accidental features were also necessary for later applications of algebra. Try to write an identity like $(a+b)^3 = a^3 + b^3 + 3a^2b + 3ab^2$ in any premodern notation and you will understand why Cardano states the rule rhetorically (Cardano 1545, f. 16a). Likewise, how could $A = \pi r^2$, $f(x) = 3x^3\sqrt{x^2+6}$, or $d = \frac{1}{2}gt^2$ be expressed if not with letters that stand for values that are joined through operations?

We can credit Book VII of Pappus's *Collection* with playing a significant role in inspiring both Viète's renovation of algebra and Fermat's and Descartes's application

of that algebra to the study of curves. But even if these three authors worked in the sphere, or at least in the shadow, of classical Greek mathematics, it was they who paved the way for the eventual abandonment of geometry in favor of the new algebra for conducting original work in mathematics, and also for the slow demise of premodern algebra in favor of a numerical version of *logistice speciosa* for practitioners. Viète's algebra was supposed to be a restoration of ancient analysis. Instead, ultimately it made obsolete both the geometrical analysis of Pappus and the arithmetical analysis (premodern algebra) of Diophantus.

Abstract

In ancient Greek mathematics, the general term μέγεθος stands for geometric magnitudes of all kinds. Euclid's book V develops a theory of magnitudes, their ratios, and proportions. Viewed from the modern perspective, the theory of proportions is a technique of processing ratios. In early modern mathematics, it was replaced by implicit rules of an ordered field, then, in the nineteenth century, by the arithmetic of real numbers. We formalize Euclid's theory from book V and show how it was reshaped in Descartes' *La Géométrie.*

Keywords

Magnitude · Ratio · Proportion · Algebra of line segments · Arithmetic of line segments · Ordered field · Real closed field · Descartes' plane

1 Introduction

Descartes' 1637 *Discours de la Méthode pour bien conduire sa raison, et chercher la vérié dans les sciences, plus la Dioptrique, les Météores et la Géométrie qui sont des essais de cette Méthode* (Descartes 1637b) consists of the philosophical essay *Discourse on Method* and three scientific treaties, as we would could call them today. Each of them contains spectacular discovery. In *Meteores,* Descartes provides widely accepted explanation of the rainbow phenomenon. In *Dioptrics,* he derives the law of refraction, currently known as Snell's law, as well as fundamental laws concerning elliptic and hyperbolic lenses. In *Geometry,* he presents a solution to the Pappus problem for any number of lines. The problem itself and its general solution suggested by Descartes are already forgotten. Yet, it was a novel method of solving problems in geometry that has had a far-reaching impact on mathematics and made *La Géométrie* a masterpiece of mathematical writing. Descartes' method is commonly referred to as an analytic geometry. In fact it took centuries to turn his original procedures into the modern analytic form. One aspect of that method includes operations on line segments – operations which replaced the ancient technique of proportions.

2 Euclidean Proportions

In ancient Greek mathematics, the general term μέγεθος (magnitude) covers line segments, triangles, convex polygons, circles, angles, arcs of circles, and solids. Euclid's book V develops rigorous treatment of magnitudes, their ratios, and proportions. It is one of the most thorough theories making up the *Elements.* At the same time, it calls for a formal examination. Technical terms like *greater, lesser, multitude,* and *proportion* are consistently applied throughout the course.

2.1 Foundations

We formalize magnitudes of the same kind (line segments being of one kind, triangles being of another, etc.) as an additive semigroup with a total order, $(M, +, <)$, characterized by the following four axioms:

$$\begin{aligned}
&\text{E1} \quad (\forall x, y)(\exists n \in \mathbb{N})(nx > y),\\
&\text{E2} \quad (\forall x, y)(\exists z)(x < y \Rightarrow x + z = y),\\
&\text{E3} \quad (\forall x, y, z)(x < y \Rightarrow x + z < y + y),\\
&\text{E4} \quad (\forall x)(\forall n \in \mathbb{N})(\exists y)(x = ny).
\end{aligned}$$

The term nx as applied in these formulas is defined by $nx = \underbrace{x + \ldots + x}_{n \text{ times}}$

The relation *greater than* is characterized by transitivity and the law of trichotomy; both Euclid's and Aristotle's texts provide evidence for it. Equality of line segments, angles, and arcs means congruence. Equality of figures should be interpreted in Euclid's theory of area, as explained in (Błaszczyk 2018); equality of solids involve an analogous theory developed in book XII of the *Elements.*

The symbol + interprets arguments like the following: "And since AG [a] is equal to E [a], and CH [c] to F [c], thus AG, F [$a + c$] is equal to CH, E [$c + a$]" (V.25), that is[1]

$$a + c = c + a.$$

Thus, in the text, instead of *AG* + *F*, or *AG and F*, we find the term *AG, F.* Moreover, we interpret the equality *AG, F* = *CH, E* as the commutative property. In a similar way, we could show that the addition of magnitudes is an associative operation. By alike textual analysis we could certify axioms E2 and E3.

Note that in book V, magnitudes are represented by line segments, hence the term *AG, E* finds an obvious interpretation as a concatenation of two lines. Yet the results of book V are applied to magnitudes of any kind. In general, viewed from the methodological perspective, the addition of magnitudes should be treated as a primitive concept. Nonetheless, within Euclid's theory of equal figures, the sum of squares could be defined as a square determined on the ground of proposition I.47, and the sum of similar figures as a figure similar to the ones being added, determined on the ground of proposition VI.31.[2]

E1 interprets definition V.4, the so-called Archimedean axiom: "Magnitudes [x, y] are said to have a ratio with respect to one another which, being multiplied *[nx]* (πολλαπλασιαζόμενα), are capable of exceeding one another [$nx > y$]."

The term *nx* stands here for the phrase *multiple of the magnitude.*

Axiom E1 is applied in book V only once: in the proof of proposition V.8. Then, in a modified form, it is applied in proposition X.1 on incommensurable lines.

[1] English translations of the *Elements* after (Euclid 2007). The accuracy of this edition is easy to verify since it also includes the Greek text of the classic Heiberg's edition (Heiberg 1883).

[2] See (Błaszczyk 2018; Błaszczyk and Petiurenko 2020) respectively.

Geometry developed in books I-IV of the *Elements* does not rely on E1 and can be modeled on a non-Archimedean plane. It can be shown that without E1 proposition V.8, crucial for the theory, does not hold. Yet, the theory of similar figures as developed in book VI builds on results of book V, hence Euclidean similar figures should be modeled on an Archimedean plane.

E4 is implicitly applied in proposition V.5. This axiom is not essential, as it can be derived from the remaining four, i.e., E1-E3, and E5 as presented below.

Next to sums and relation *greater than,* book V introduces yet another relation on magnitudes, namely proportion. In Greek manuscripts, it is rendered by the schematic phrase τὸ A πρὸς τὸ B, οὕτος τὸ Γ πρὸς τὸ Δ ("as A is to B, so is C to D"). For a symbolic representation of proportion, we adopt the term x: y:: z: υ. In fact, this symbol was introduced already in the seventeenth century.[3] Descartes did not apply any symbolic shortcuts for proportions and mimics Euclid's phrase.

Definition V.5 clearly brings in the proportion in a verbal form. We interpret it by the following formula:

$$x : y :: z : \upsilon \Leftrightarrow_{df} (\forall m, n \in \mathbb{N})[(nx > 1my \Rightarrow nz >_2 m\upsilon) \wedge \\ \wedge (nx = my \Rightarrow nz = m\upsilon) \wedge (nx <_1 my \Rightarrow nz <_2 m\upsilon)].$$

The assumption regarding magnitudes *x, y,* on the one hand, and *z, υ,* on the other, being of the same kind is formalized by $x, y \in \mathcal{M}_1 = (M_1, +<_1)$ and $z, \upsilon \in \mathcal{M}_2 = (M_2 + <_2)$.

Definition V.7 introduces a relation *greater than* between pairs of magnitudes. We interpret it as follows:

$$x : y \succ z : \upsilon \Leftrightarrow_{df} (\exists m, n \in \mathbb{N})[(nx >_1 my) \wedge (nz \leq_2 m\upsilon)].$$

Thus, the structure of magnitudes is an ordered semigroup equipped with the four-ary relation of proportion, *(M, +, ::, <)*. Due to the proportion, we need to amplify its characteristic by another axiom, namely

$$\text{E5}\ (\forall x, y, z)(\exists \upsilon)(x : y : z : \upsilon).$$

E5 represents the so-called fourth proportional axiom. In book V, it is applied in proposition V.18. Next, it is explored in the method of exhaustion (see e.g. XII.1).

2.2 The Use of Proportions

Propositions of book V provide the bases for the theory of similar figures as developed in book VI. Descartes applies it all throughout *Geometry, Dioptrics,* and in his essay on the rainbow included in *Meteores.*

In book VI, there is only one explicit reference to definition V.5, namely, in the proof of proposition VI.1. Other propositions apply VI.1 and results of book V. To

[3] See (Cajori 2007), p. 197.

explain how they enable to process ratios, we present a sample stylized on algebra. This modern attire is to reveal similarities between proportions and the arithmetic of fractions.

V.9 $a: c :: b : c \Rightarrow a = b.$
V.12 a: b :: $c : d$, $a : b :: e : f \Rightarrow a : b :: (a + c + e) : (\mathrm{b} + d + f)$.
V.16 a: b :: $c : d \Rightarrow a : c :: b : d$.
V.22 $a: b :: d : e$, $b : c :: e : f = a : c :: d : f$.
V.23 $a: b :: e : f$, $b : c :: d : e \Rightarrow a : c :: d : f$.
V.24 $a: c :: d : f$, $b : c :: e : f \Rightarrow (a + b) : c :: (d + e) : f$.

When proportion $a : b :: c : d$ is replaced with the equality of fractions $\frac{a}{b} = \frac{c}{d}$, the above propositions will turn into simple rules of the arithmetic of fractions. However, not the other way around, e.g., the seemingly obvious rule: if $\frac{a}{b} = \frac{c}{d}$, then $ad = bc$, finds no counterpart in book V. The term $ad = bc$ could be interpreted in terms of figures rather than proportions (see. VI.16). Note also that ratio $a : b$ is not an individual object as it has to be a part of the 4-ary relation like $a : b :: c : d$ (see Błaszczyk and Petiurenko 2019).

In the context of transformation of Euclidean proportionality, one crucial difference is this: while Euclid's V.9 relies on the Archimedean axiom, its ordered field counterpart holds in any field, be it Archimedean or non-Archimedean.

Summarizing this section, the structure $(M, +, ::, <)$ as characterized by the above five axioms E1-E5 represents the ancient Greek magnitudes of the same kind, especially line segments.[4]

3 Descartes' Algebra of Line Segments

On the very first pages of (Descartes 1637a), Descartes introduces brand new operations on line segments: multiplication, division, and the square root.[5] They are defined in such a a way that $a \cdot b$, $\frac{a}{b}$,, and $\sqrt{a}$ are line segment, given a, b are line segments. Hence, for example, a^2, a^3, a^4 etc., or $\sqrt{a^3 - b^2}$, are lines segments. This bold innovation allows Descartes to generalize the Pappus problem to any number of lines, while Greeks could consider only four, five, or six lines. He can also consider "curve[s] of degree next higher than that of the conic sections" (Descartes 1637a, 307), in fact, of any degree, i.e., curves characterized by sums of terms such as $ax^n y^m$, for any $n,m \geq 0$.

[4] For detailed analysis leading to axioms for book V, see (Beckmann 1967), or (Błaszczyk and Mrówka 2013); the other study provides also independence results. Commonly referred (Mueller 2006) basically follows Beckmann's reading. Beckmann (1967) and Błaszczyk and Mrówka (2013) differ on some issues, yet these disagreements are irrelevant in the context of this chapter.

[5] Descartes scholars use to call it algebra and in this section we adopt this label.

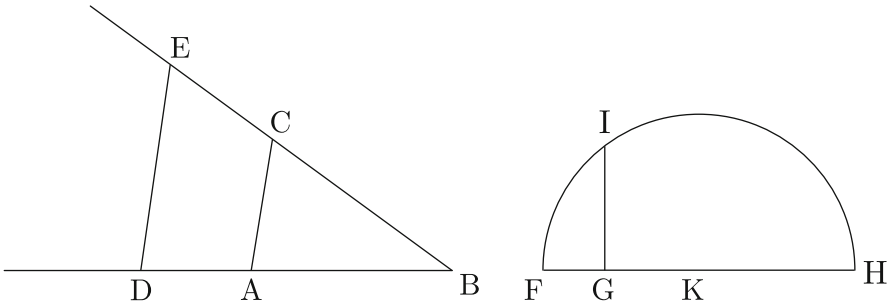

Fig. 1 *La Géométrie,* p. 297

Descartes' definitions (of a kind) are diagram based (see Fig. 1). They read[6]: "let AB be taken as unity, and let it be required to multiply BD by BC. I have only to join the points A and C, and draw DE parallel to CA; then BE is the product of BD and BC. If it be required to divide BE by BD, I join E and D, and draw AC parallel to DE; then BC is the result of the division. If the square root of GH is desired, I add, along the same straight line, FG equal to unity; then, bisecting FH at K, I describe the circle FIH about K as a center, and draw from G a perpendicular and extend it to I, and GI is the required root" (Descartes 1637a, 298).[7]

In Fig. 1, the diagram on the left refers to Euclid's proposition VI.12 on finding the fourth proportional to three given lines. Next to lines BD, BC which are to be multiplied, Descartes assumes the unit line $AB = 1$, "line which I shall call unity in order to relate it as closely as possible to numbers, and which can in general be chosen arbitrarily" (Descartes 1637a, 297). The diagram on the right refers to proposition VI.13 on finding the line in mean proportion to two given straight lines. In this case, Descartes applies Euclidean construction to the line GH and the unit line FG.

Since Euclid's geometry provides the context for these definitions, the line AB has to be arbitrary. Contrary to hyperbolic geometry, there is no basis for a unique line segment in Euclidean geometry. The angle $\angle EBD$ is also an arbitrary choice.

For comparison sake, Hilbert (Hilbert 2015) develops an algebra of line segments in a separate way.[8] It relies on the parallel axiom but not on the Archimedean axiom.

[6] English translations of (Descartes 1637a) after (Smith and Lathan 2007). Occasionally we modify Smith's version, still, these amendments are easy to verify, since (Smith and Lathan 2007) also includes facsimile of the first edition of *La Géométrie*.

[7] The passage continues as follows: "I do not speak here of cube root, or other roots, since I shall speak more conveniently of them later." Descartes' mesolabium (Descartes 1637a, 317–319) provides means to construct cube and other roots of a line segment; it also enables one an alternative construction of the square root.

[8] In this section, we adopt a methodological perspective. Crippa (Crippa 2017) takes Hilbert's arithmetic as an opportunity for far-reaching conclusions. He points out that while in Hilbert's system the unit line is fixed once for all, in *La Géométrie*, it varies from a problem to a problem. As a result, he argues, the generality in Descartes' system "is achieved by means of analogy, in a similar manner to Euclid's theory" (Crippa 2017, 1255). The Greek term.ἀναγογία literally means analogy, technically – proportion. We argue that Descartes transforms the ancient technique of proportion into operations in an ordered field. In this context, *analogy* as used by Crippa is a meaningless term.

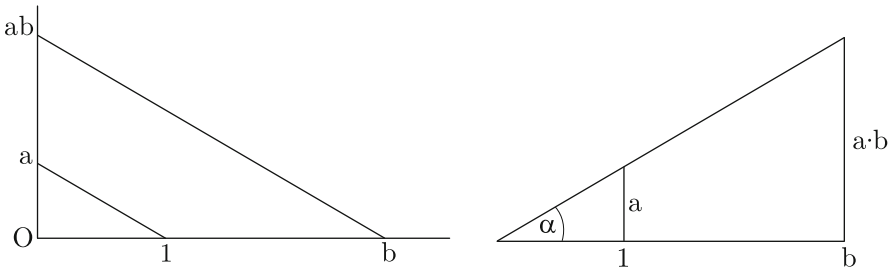

Fig. 2 Hilbert's *Grundlagen,* p. 33 (left). An alternative view on Hilbert's product (right)

It also applies an arbitrary unit segment, yet the choice of the angle depends on the line a in such a way that tg $\alpha = a$ (see Fig. 2, the diagram on the right). Definition of the product enables to determine the segment $\frac{1}{a}$, hence the quotient $\frac{b}{a}$. Hilbert's algebra, though, includes line segments of the form $\sqrt{1+a^2}$, rather than square roots $\sqrt{a}$.

As a result, there are models of Hilbert's plane which are not models of Euclidean plane.[9]

Adopting standards of the modern methodology, Hilbert's definition of the line segment *ab* is correct. As for Descartes, the status of lines introduced through his diagrams is not that clear. His statements to the effect "BE is the product of BD and BC," "BC is the result of the division," and "GI is the required root" are ambiguous. The term "is the product/quotient/root" can mean "is the product etc., based on a definition" or "is the product etc., based a theorem"? Moreover, all throughout *La Géométrie,* Descartes implicitly applies rules such as.[10]

$$ab = ba,\ \ a(b+c) = ab + ac,\ \ \sqrt{a^2} = a,\ \ \left(\sqrt{a}\right)^2 = a,\ \ a \cdot 1 = a,\ \ a < b \Rightarrow ac < bc. \tag{1}$$

They seem obvious, though, from the perspective of the modern theory of ordered fields, or just the arithmetic of real numbers. However, in view how Descartes introduces new operations, these rules are by no means *clear and obvious,* and they can hardly be taken for granted.[11]

[9] See (Hartshorne 2000), p. 187.

[10] Bos (Descartes 1637a), in a footnote on page 300, includes such a strong comment: "The interpretation of multiplication and division by means of a unit was not used in *Geometry* at all." We argue that via the rules of an ordered field, like these listed in (1), multiplication, division, and square root are applied in processing of formulas all throughout *Geometry.*

[11] Mancosu (Mancosu 1996), in regard to Descartes' *definition* of the product, states: "Then construction of *ab* is as follows [...] This is done by joining A and C and drawing the line DE parallel to AC. Then $BE = BD \cdot BC = ab$. The claim is easily verified by exploiting the proportionality between the triangles ABC and DBE" (Mancosu 1996, 67). The similarity (or less formally, proportionality) of triangles *ABC* and *DBE* results in the following proportion *BE*: *BC*:: *BD*: 1. In the next section, we show how to derive from it the equality $BE = BD \cdot BC$. Yet, to this end we need a definition of the product of line segments.

3.1 From Greek Proportion to Descartes' Algebra of Line Segments

Next to the implicit use of the rules of an ordered field, the most intriguing part of Descartes algebra is the implicit way how he turns Euclid's proportions into his new operations. In symbols, it could be rendered as follows:

$$a : b :: c : d \Rightarrow a \cdot d = c \cdot b, \quad a : b :: c : d \Rightarrow a = \frac{c}{d} \cdot b. \tag{ED}$$

Below we provide textual evidence. The following passage refers to Fig. 3.

"For, putting a for BD or CD, and c for EF, and x for DF, we have CF $= a - x$, and since CF or $a - x$ is to FE or c, as FD or x is to BF, which is consequently $\frac{cx}{a-x}$" (Descartes 1637a, 389).

In this passage, Descartes explains how to find roots of a fourth-degree polynomial. Details of his solution are irrelevant to the discussed issue, so we skip them. To simplify the view, we mark in blue parts referring to Euclid's theory of similar triangles, and in red those referring to Descartes' algebra. Thus, since $\Delta CFE \sim \Delta DFB$, the following proportion holds CF : FE :: FD : BF, or, adopting Descartes' alternative notation, $(a - x) : c :: x : BF$. Then, all of a sudden, Descartes declares that $BF = \frac{cx}{a-x}$. The rule (ED) enables one to justify that step, however, in *La Géométrie* there is no hint concerning that transformation.

The discussed passage is by no means accidental. The revealed argument, as encoded by the rule (ED), is applied whenever Descartes invokes Euclid theory of similar figures, that is, all throughout *La Géométrie.*

In sum, given that M stands for the set of line segments, Descartes' algebra is represented by the structure $\left(M, +, \cdot, \div, \sqrt{}, 1, <\right)$. In Sect. 5 below, we will show how it expands by including *negative* line segments.

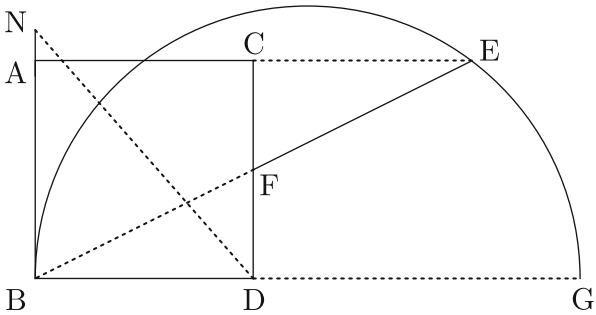
4 Arithmetic of Line Segments 4.1 Defining Descartes' Operations

Going back to Descartes' definitions and rules exemplified in (1), they could be justified in a purely geometrical manner (via proposition VI.2) or on the grounds of book V. Below, we sketch the second option starting with definitions, see formulas (2) and Figs. 4, 5, and 6 respectively.

$$\begin{aligned} &x = a \cdot b \text{iff} 1 : b :: a : x, x = \frac{a}{b} \text{iff} a : b :: x : 1, \\ &x = \sqrt{a} \text{iff} 1 : x :: x : a. \end{aligned} \tag{2}$$

Following these definitions, we can put lines a and 1 on any arm of the angle. Then, instead of $1 : b :: a$: x, by definition V.5, we can also take $b : 1 :: x$: a. Now, the product ab is given by the proportion b : 1 :: ab : a, while ba is given by the

Fig. 3 *La Géométrie,* p. 389



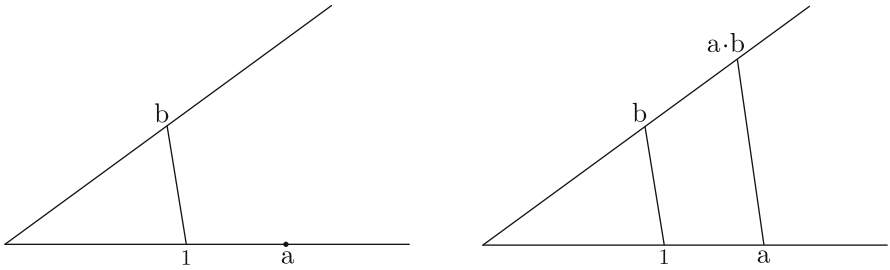


Fig. 4 Definition of multiplication

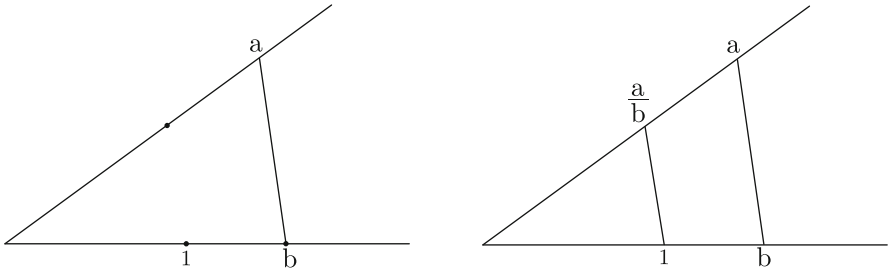

Fig. 5 Definition of division

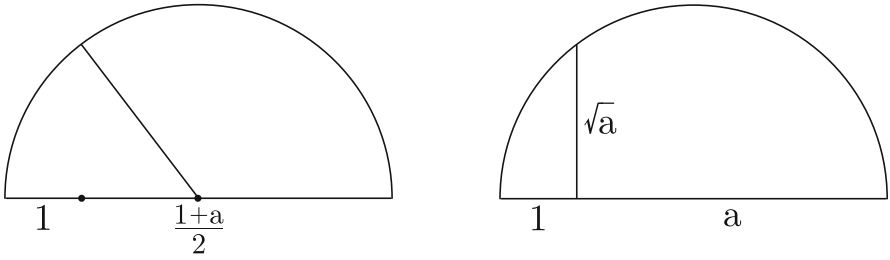

Fig. 6 Definition of square root

proportion $a : 1 :: ba : b$. From these proportions, by V.23, it follows that $ba : 1 :: ab : 1$. Hence, by V.9, $ba = ab$.[12]

For the rule (ED), suppose the proportion $a : b :: c : d$ obtains. According to the definition of division, we have

$$a : b :: \left(\frac{a}{b}\right) : 1, \quad c : d :: \frac{c}{d} : 1.$$

These three proportions give $\left(\frac{a}{b}\right) : 1 :: \left(\frac{c}{d}\right) : 1$. Hence, again by V.9, we get $\frac{a}{b} = \frac{c}{d}$. Finally, since $a = \frac{a}{b}b$, the equality $a = \frac{c}{d}b$ obtains.

5 The Field of Line Segments

The idea of a *negative* line segment in *La Géométrie* is related to roots of polynomials under the cover of *false* roots. Yet, Descartes' concept of a root evolves throughout the essay from an equation between lines to a polynomial equation $\varphi(x) = 0$.

5.1 True and False Roots

In book I, Descartes shows how to construct roots of the equation $z^2 = az + bb$. Since the solution segment line z can be found by straightedge and compass, he writes: "this root (*racine*) or unknown line can easily be found."[13] The discussed equation is presented as the equality between lines, rather than in the polynomial form $z^2 - az - b^2 = 0$. Then, Descartes considers two other versions of this equation, namely $z^2 = az - bb$ and $z^2 = -az + bb$. Minus sign as it appears in these equations should be interpreted from the perspective of the axiom E2, i.e., equations make sense whenever $az \geq b^2$ and $az \leq \mathrm{b}^2$, respectively. Descartes does not consider the case $z^2 = -az - bb$ at all, for the line segment z^2 would be equal to a *negative* line segment $-(az + bb)$.

In book III, he adopts a more liberal concept of a root: it is a line segment x satisfying a polynomial equation $\varphi(x) = 0$. At the same time, his concept of a root of a polynomial appears to be close to the modern one as he writes:

"the sum of an equation $[\varphi(x)]$ having several roots is always divisible by a binomial consisting of the unknown quantity diminished by the value of one of the true *(vrayes)* roots $[(x - a)]$, or plus the value of one of the false (*fausse*) roots $[(x + a)]$. [. . .] On the other hand, if the sum of the terms of an equation is not divisible by a binomial consisting of the unknown quantity plus or minus some other quantity, then this latter quantity is not a root of the equation" (Descartes 1637a, 372). That is,

$$\varphi(a) = 0 \Leftrightarrow (x - a) \mid \varphi(x),$$

[12] See (Hilbert 2015), p. 34 to check how Hilbert proves the law $ab = ba$.

[13] For details see Sect. 6.1 below.

assuming a could be positive or negative. Thus, false roots are line segments taken along with a special sign "–."

False roots are more widely discussed in the following passage:

"It often happens, however, that some of the roots are false (*faussent*) or less than nothing (*moindres que rein*). Thus, if we suppose x to represent the defect (*defaunt*) of a quantity 5, we have $x + 5 = 0$ which, multiplied by $x^3 - 9xx + 26x - 24 = 0$, yields $x^4 - 4x^3 - 19xx + 106x - 120$, an equation having four roots, namely three true roots, 2, 3, and 4, and one false root" (Descartes 1637a, 372).

Despite linguistic maneuvers, the mathematical meaning of the false root -5 comes straight from the following factorization of the polynomial

$$(x + 5)(x - 2)(x - 3)(x - 4) = x^4 - 4x^3 - 19xx - 120.$$

Thus, algebra of polynomials ensures meaning to *negative* line segments.

5.2 Zero and Sign Rules

These specific objects, i.e., *negative* line segments, are included into the algebra of line segments due to implicit sign rules as explained below.

"Every equation can have as many distinct roots *(racines),* that is values *(valures)* of the unknown quantity as the number of dimensions of the unknown quantity in the equation. Suppose, for example, $x = 2$ or $x - 2 = 0$, and again, $x = 3$, or $x - 3 = 0$. Multiplying together the two equations $x - 2 = 0$ and $x - 3 = 0$, we have $xx - 5x + 6 = 0$, or $xx = 5x - 6$. This is an equation in which x has the value 2 and at the same time x has the value 3. If we next make $x - 4 = 0$ and multiply this by $xx - 5x + 6 = 0$, we have $x^3 - 9xx + 26x - 24 = 0$ another equation, in which x, having three dimensions, has also three values, namely, 2, 3, and 4" (Descartes 1637a, 397). Descartes does not justify relations like $2 - 2 = 0$, $3 - 3 = 0$, or just the model one.

$$1 + (-1) = 0 \tag{3}$$

They are part of his practice of processing polynomials. In the like manner, while multiplying binomials, he implicitly adopts the following sign rules:

$$(-1) \cdot (-1) = 1, \quad (+1) \cdot (-1) = -1. \tag{4}$$

Indeed, rules (3) and (4) are enough to process *true* and *false* line segments.

5.3 Constructing False Roots

In Descartes' theory of polynomials, the final step in finding roots is their construction. Like common roots, false roots also have to be constructed. A solution to angle trisection illustrates how it is possible. Descartes managed to reduce the problem to

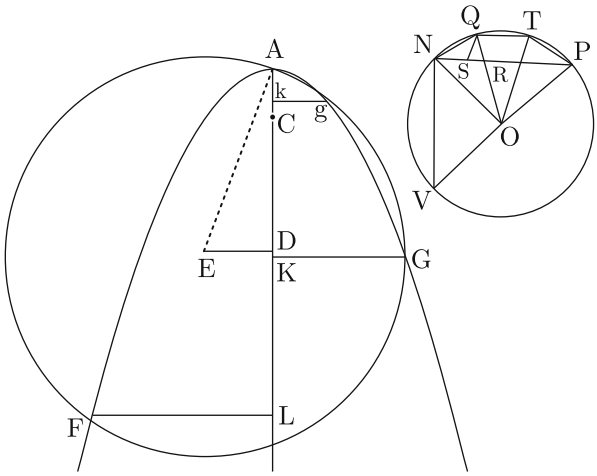

Fig. 7 *La Géométrie,* p. 399. Construction of roots (left). Forming an equation (right)

finding roots of the polynomial $z^3 - 3z + q = 0$ (see Descartes 1637a, 396–397). These roots are determined by intersections of a circle and parabola (see Fig. 7). Lines *kg* and *KG* are true roots, while *FL* is the false root, i.e., $(-FL)^3 - 3(-FL) + q = 0$. For a verification, one has to specify the characteristics of the circle and parabola, and apply rules (3) and (4).

5.4 Ordered Field of Line Segments

Let us assume M is the set of line segments. Let $-M = \{-x : x\ G\ M\}$ be the set of negative line segments, and $\mathbb{F} = -M \cup \{0\} \cup M$ be the set of common and *negative* line segments. Hence, adopting the above rules (3) and (4), the algebra $(\mathbb{F}, +, \cdot, 0, 1)$ is the field of line segments. Moreover, following the ideas of Artin and Schreier (Artin and Schreier 1926), since the set M is closed under sums and products, and $0 \notin M$, the order defined, by

$$x < y \Leftrightarrow y - x \in M,$$

makes the field $(\mathbb{F}, +, \cdot, 0, 1)$ an ordered field $(\mathbb{F}, +, \cdot, 0, 1, <)$. This simple observation justifies the actual practice of processing line segments throughout book III of *La Géométrie.*[14]

[14] Wallis (Wallis 1685), chapter LXVI, introduces negative numbers via the so-called number line. From the mathematical perspective, it builds on an ordered group $(G, +, 0, <)$. Descartes' way of introducing negative numbers builds on algebraic group $(G, +, 0)$, while the total order is generated by the above definition.

6 Applications

6.1 Pythagorean Theorem

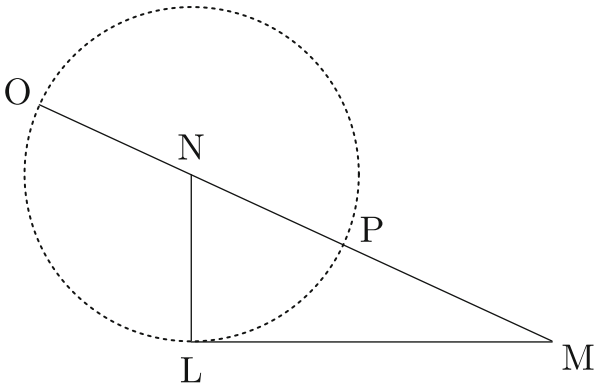
Euclid's proposition I.47 provides ancient Greek version of the Pythagorean theorem. It reads: "The square on (ἀπό) the side subtending the right-angle is equal to the [sum of] squares on (ἀπό) the sides surrounding the right-angle." The proposition ἀπό refers to the construction included in I.46, which reads: "[D]escribe a square on (ἀπό) a given straight line."

While the interpolation *sum of* characterizes modern translations, in the Greek mathematics, instead of *sum of* squares, just squares were considered, as exemplified by the *diorismos*' part of I.47: "the square on BC is equal to the squares on BA, AC."

Clavius (Clavius 1589), one of the most popular seventeenth-century editions of the *Elements,* includes essentially the same version of I.47.[15] Therefore we adopt the perspective that the following scheme □ , □ = □ accurately represents pre-Cartesian form of the Pythagorean theorem. In *La Géométrie,* however, it gets a new, modern-like form, namely $a^2 + b^2 = c^2$, where *a,b* are legs, and *c* is the hypotenuse of a right angle triangle. Symbols a^2, b^2, c^2 stand for line segments, and the Pythagorean formula makes sense within the framework of Descartes' arithmetic.[16] Here is textual evidence (the following passage refers to Fig. 8).

"this root *(racine*) or unknown line can easily be found. For example, if I have $z^2 = az + bb$, I construct a right triangle NLM with one side LM, equal to b, the square root of the known quantity bb, and the other side LN, equal to $\frac{1}{2}a$, that is, the half of other known quantity, which was multiplied by *z,* which I supposed to be the unknown line. Then prolonging MN, the base of this triangle, to O, so that

Fig. 8 *La Géométrie,* p. 302



[15] See (Clavius 1589), 229.

[16] In the modern mathematics, letters *a, b, c* as applied in the Pythagorean formula represent lengths of sides of a triangle, i.e., real numbers, rather than sides of the triangle.

NO is equal to NL, the whole line OM is the required line z. It is expressed in the following way (Descartes 1637a, 302)":

$$z = \frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}.$$

In this passage, Descartes shows how to construct roots of the equation $z^2 = az + bb$. Line segment $OM = z$ is to be the required root. It is composed of $ON = \frac{1}{2}a$ and the line segment NM identified by the formula $\sqrt{\frac{1}{4}aa + bb}$. Descartes' argument breaks at this stage. We could easily support it by the equation $\left(\frac{1}{2}a\right)^2 + b^2$.[17]

We can verify Descartes' solution algebraically, in a contemporary way, since by substitution the equation

$$\left(\frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}\right)^2 = a\left(\frac{1}{2}a + \sqrt{\frac{1}{4}aa + bb}\right) + bb,$$

is reduced to the identity $0 = 0$, given that

$$\left(\sqrt{\frac{1}{4}aa + bb}\right)^2 = \frac{1}{4}aa + bb.$$

Indeed, that is how, i.e., *par le calcul,* Descartes verifies that specific lines are roots of the equation $z^3 = 3z - q$ (see Descartes 1637a, 397).[18]

For another example, let us return back to Fig. 3. The following passage resumes the argument and presents the follow up:

"For, putting a for BD or CD, and c for EF, and x for DF, we have CF $= a - x$, and since CF or $a - x$ is to FE or c, as FD or x is to BF, which is consequently $\frac{cx}{a-x}$. Now, since in the right triangle BDF one side is x, and other is a, their squares, which are *(leurs carrés, qui sont)* $xx + aa$, are equal to the square of the base, which is $\frac{ccxx}{xx-2ax+aa}$" (Descartes 1637a, 389).

[17] Bos (Bos 2001), p. 300, interprets Descartes' solution as follows: "[the solution of the equation $z^2 = az + bb$] involved the root $\sqrt{\frac{1}{4}aa + bb}$. Descartes did not interpret this root by means of the unit, but classically (and indeed much more naturally) as the hypotenuse of a right-angled triangle with sides 1 $2a$ and b." Whatever means *classically*, or *naturally* in this context, the formula $\frac{1}{4}aa + bb$ refers to the Pythagorean theorem, while the formula $\sqrt{\frac{1}{4}aa + bb}$ identifies the hypotenuse of the triangle ΔNLM.

[18] Bos (Bos 2001), p. 305 suggests geometric verification of Descartes' solution. Yet, Descartes refers back to that solution in (Descartes 1637a), p. 326. Then, a formula under the square root has no other geometrical meaning but a line segment. See Sect. 7.2 below.

Thus, in the right angle triangle *BFD,* with $FD = x$, and $BD = a$, the square of the hypotenuse BF (Descartes names it *the base*) is clearly identified with the line $x^2 + a^2$, that is

$$x^2 + a^2 = BF^2.$$

Moreover, in this passage, we can also spot a word pattern *leurs carrés, qui sont* consistently used in *La Géométrie.*[19] It is also used in Latin translation of Pappus, where the phrase "if there be given a ratio (λόγος;) of the rectangle contained by the two lines so drawn to the square on the third" is interpreted as follows: "let there be a proportion (*proportio*) of the rectangle contained by the two lines so draw to the square of the third (ad *quadratum reliquæ*)."[20]

Thus, the phrase *square of* which makes sense within the framework of *La Géométrie* replaced *square on* which refers back to Euclidean paradigm. On the level of symbols, the ancient schematic phrase "the square on BC is equal to the squares on BA, AC" was replaced by the formula $a^2 + b^2 = c^2$.

6.2 Formula for a Curve

Arithmetic of line segments plays the crucial role in how Descartes derives the formula for a curve consisting of intersections of moving lines. In the Fig. 9, the straight line GCL turns around the pivot point G, while the line CNK moves along some other straight line (the vertical one). The line CNK is identified by its slope *KL/NL;* since $KL = b$, $NL = c$, in the formula of the curve, it is represented by the term $\frac{b}{c}$. The intersection point $C = C(x,y)$ is identified by two line segments $BA = x$, $CB = y$. Moreover, $GA = a$. A formula for the resulting curve is a polynomial relation between x and y. The relevant passage of *Geometry* reads as follows:

"Then I say that as NL is to LK, or as c is to b, so CB, or y, is to BK, which is therefore equal to $\frac{b}{c}y$. Then BL is equal to $\frac{b}{c}y - b$, and AL is equal to $x + \frac{b}{c}y - b$. Moreover, as CB to LB, that is, as y is to $\frac{b}{c}y - b$, so AG or a is to LA or $x + \frac{b}{c}y - b$. Multiplying the second by the third, we get $\frac{ab}{c}y - ab$ equal to $xy + \frac{b}{c}yy - by$, which is obtained by multiplying the first by the last. Therefore, the required equation is.

$$yy = cy - \frac{cx}{b}y + ay - ac" \quad \text{(Descartes 1637a, 321–322).}$$

[19] Here is other occurrence of this standard: "*ss, qui est le carreé de la baze*, *qui sont les carées des deux* ([Descartes 1637a], 342).

[20] See (Descartes 1637a), 305. Descartes cites, probably, (Pappus 1588), p. 165. It is puzzling what Commandino meant by saying "square of the third." Oaks (Oaks 2018), p. 251–252, referring to another passage of (Pappus 1588), observes: "Squares and cubes were worded with the proposition *ex* ("of")," yet this phrase stood for squares on. For the Greek text of Pappus see (Pappus 1877), vol. II, 676.

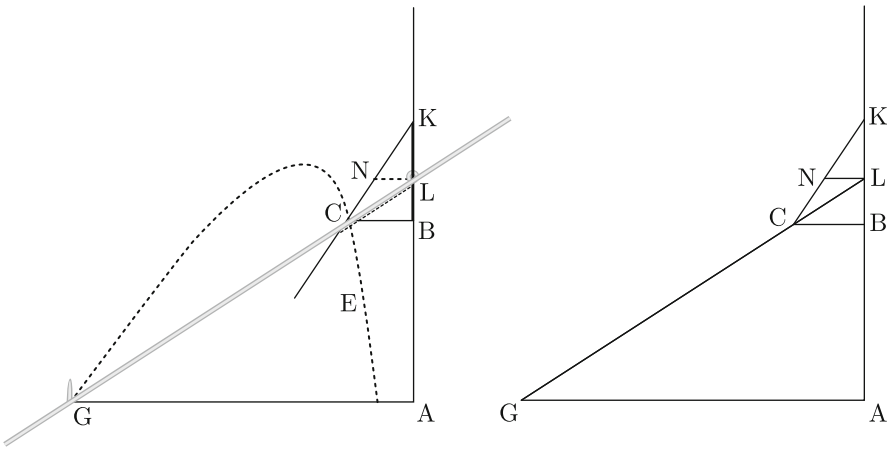


Fig. 9 Descartes's hyperbola. On the left, diagram from *La Géométrie,* p. 320

Derivation of the formula for the line EC (actually it is a hyperbola) initially employs Euclid's theory of similar figures. Since $\Delta NKL \sim \Delta CKB$, the proportion $NL : KL :: CB : BK$ obtains. It is simplified to the following form $c : b :: y : BK$. Yet, Descartes' conclusion is far more reaching, namely

$$c : b :: y : BK \Rightarrow BK = \frac{b}{c}y. \tag{5}$$

As a result, $LB = \frac{b}{c}y - b$, and $LA = x + \frac{b}{c}y - b$.

In the next step, since $\Delta CLB \sim \Delta GLA$, the proportion $CB : LB :: AG : LA$ obtains, or

$$y : \left(\frac{b}{c}y - b\right) :: a : \left(x + \frac{b}{c}y - b\right).$$

Again, by the implicit use of the rule (ED), Descartes could turn that proportion into the following equation

$$a\left(\frac{b}{c}y - b\right) = y\left(x + \frac{b}{c}y - b\right). \tag{6}$$

However, he actually writes

$$\frac{ab}{c}y - ab = xy + \frac{b}{c}yy - by. \tag{7}$$

In order to simplify (6) to (7), one needs to apply rules of an ordered field. And finally, to get from (7) the equation of the hyperbola, namely

$$yy = cy - \frac{cx}{b}y + ay - ac,$$

one should apply, again, rules of on ordered field.

7 Pappus Problem

7.1 Formula for *Locus*

The Pappus problem is the main theme of *La Géométrie.* It is a question of *locus.* For four lines, it requires to find the *locus* of such points C that lines drawn from C meet the given lines at given angles and satisfy (in a simplified version) the following condition: the rectangle contained by two of them is equal to the rectangle contained by the other two. Accordingly, a required condition for six lines takes this form: the (right rectangular) prism contained by three lines is equal to the prism contained by the other three. However, Pappus believed that the problem for more than six lines was meaningless, "since there is no figure of more than three dimensions."[21]

Descartes interprets the Pappus problem in his arithmetic of line segments, while the *locus* of the point C – in terms of a formula for a curve. He discusses the four lines problem in great detail. At first, he derives a formula for the *locus*, then draws (constructs) that *locus*, and finally, explains "all the given quantities by numbers."

Thus, Descartes assumes that straight lines EF, AD, AG, and GF are given "in position," which actually means that angles $\angle DAB$, $\angle FEA$, and $\angle AGH$ are given, moreover k,l are also given, where $EA = k$, $AG = l$ (see Fig. 10). He seeks a curve consisting of points $C = C(x, y)$, where $AB = x$, $BC = y$, such that segment lines CB, CD, CF, and CH, drawn from C to the given lines, make given angles α, β, γ, and δ respectively, and moreover they satisfy the following condition

$$CB \cdot CF = CD \cdot CH \tag{8}$$

The assumption on angles, specifically on $\angle DAB$ and α, amounts to knowing all angles in the triangle ΔARB (see Fig. 12). Then, Descartes considers one by one triangles

$$\Delta DRC, \Delta ESB, \Delta FSC, \Delta BTG, \Delta CTH$$

and, similarly, determines their angles. In the next stage, he solves these triangles in order to determine lines involved in Eq. (8) in terms of x, y and the given quantities. As for the triangle ΔARB, he writes:

"Now, since all the angles of the triangle ARB are known, the ratio between the sides AB and BR is also known. I assume it is z to b. Since AB is x, then RB

[21] That problem was originally stated in book VII of Pappus' *Collection.* In (Descartes 1637a), pages 304–306, Descartes cites, probably, (Pappus 1588). The English translation of Pappus' phrase concluding this paragraph, after (Smith and Lathan 2007), p.

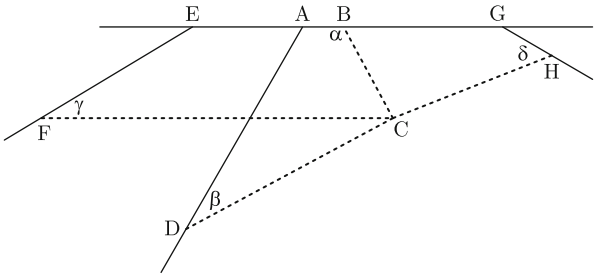

Fig. 10 The four lines Pappus problem

will be $\frac{bx}{z}$; and the whole CR will be $y+\frac{bx}{z}$, since B lies between C and R" (Descartes 1637a, 310).[22]

In short,

$$AB = x, AB : BR :: z : b \Rightarrow RB = \frac{bx}{z} \& CR = y + RB.$$

Indeed, the rule (ED) is implicitly used all through derivation of the formula for the sought *locus* (Fig. 11).[23]

Since all the angles of considered triangles are known, the following proportions are also known[24]

$$AB : BR :: z : b, CR : CD :: z : c, BE : BS :: z : d,$$
$$CS : CF :: z : e, ; BG : BT :: z : f, TC : CH :: z : g.$$

In result, the condition (8) is turned into the following formula

$$yy = \frac{(cfglz - dekzz)y + (-dezzx - cfgzx + bcgzx)y + bcfglx - bcfgxx}{ezzz - cgzz} \quad (9)$$

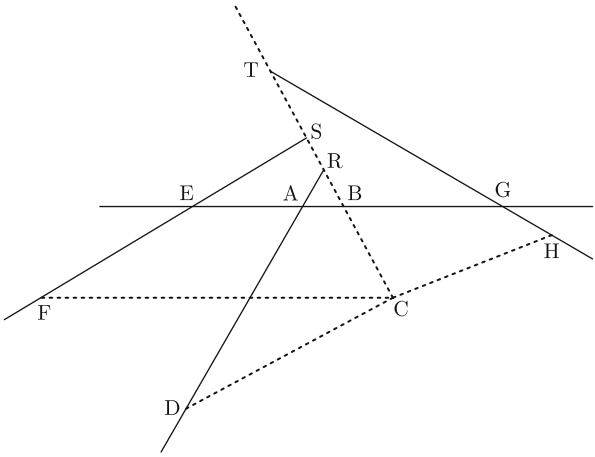
It is "the locus generated by infinity of points C, such that, if four lines CB, CD, CF, and CH be drawn through it making given angles with the given lines, the product of CB and CF is equal to the product of CD and CH" (Descartes 1637a, 325).

[22] (Smith and Lathan 2007) translates this passage as follows: "Now, since all the angles of the triangle ARB are known, the ratio between the sides AB and BR is known. If we let AB: $BR = z$: b, since $AB = x$, we have $RB = \frac{bx}{x}$; and since B lies between C and R, we have $CR = y + \frac{bx}{x}$" (Smith and Lathan 2007, 29). Symbols applied here, and in translation of pages 310–311 alike, do not distinguish between proportion and equality.

[23] Bos (Bos 2001), p. 315, footnote 6, also discusses this passage, yet does not identify the rule (ED). Indeed, he does not identify any implicit rule in (Descartes 1637a) at all. He also does not discuss the role of Euclid's proportion in theory of similar triangles applied by Descartes.

[24] In a numerical explanation provided in (Descartes 1637a), p. 333, Descartes assumes $z = 1$. Then parameters b to g have to be determined based on the axiom E5. Generally, if z is given, b to g exist, however, they are not given in the same sense as, say, $EA = k$. In Euclid's *Data*, when two lines a, b are given, their ratio is also given, which means a: b:: a: b (see Taisbak 2003, 37).

Fig. 11 La Géométrie, p. 311



We can turn Eq. (9) into the form $\psi(x,y) = 0$, where $\psi(x,y)$ is a polynomial of two variables. Otherwise, the *locus* consists of points $C = C(x,y)$, where coordinates x, y are in the relation $\psi(x,y) = 0$.

When the variable y is set, say $y = y_0$, the second coordinate, say x_0, is a root of the polynomial equation $\varphi(x) = \psi(x,y_0) = 0$. In this way, the second coordinate of point C is determined, i.e., $C = C(x_0,y_0)$.

"Since this condition can be expressed by a single equation in two unknown quantities [i.e., $\psi(x, y)$], we may give any value we please to either x or y and find the value of the other from this equation" (Descartes 1637a, 313).

This procedure enables one to determine as many points $C = C(x_0,y_0)$ as one likes and draw the curve $\psi(x, y)$ point wise. Thus, in general, a solution to Pappus problem for any number of lines is approximated rather than drawn by an instrument[25]:

"If then we should take successively an infinite number of different values for the line y, we should obtain an infinite number of values for the line x, and therefore an infinity of different points, such as C, by means of which the required curve could be drawn" (Descartes 1637a, 313).

Nevertheless, the locus for the four lines problem can be drawn, and Descartes studies it carefully.

7.2 Constructing *Locus*

For the economy of calculations, Descartes introduces new parameters,

[25] Note that according to modern standards, a solution is reached when a formula for a curve is given, since we have techniques of studying curves based on their formulas alone. However, as Descartes discovered a formula for a curve, it could hardly be an accepted solution at that time.

$$2m = \frac{cfglz - dekzz}{ez^3 - cgzz}$$
$$\frac{2n}{z} = \frac{dezz + cfgz - bcgz}{ez^3 - cgzz}$$
$$o = -\frac{2mn}{z} + \frac{bcfgl}{ez^3 - cgzz},$$
$$-\frac{p}{m} = \frac{nn}{zz} - \frac{bcfg}{ez^3 - cgzz}$$

As a result, the Eq. (9) takes a simplified form

$$yy = 2my - \frac{2n}{z}xy + \frac{bcfglx - bcfgxx}{ez^3 cgzz} \tag{10}$$

He treats (10) as a quadratic equation in variable y – that is $y^2 = ay + b^2$ – and determines its root by the method exposed in Sect. 6.1 above, that is $y = \frac{1}{2}a + \sqrt{\frac{1}{4}a^2 + b^2}$. In this way[26]

$$y = m - \frac{n}{z}x + \sqrt{mm + ox - \frac{p}{m}xx}. \tag{11}$$

Then Descartes constructs such points *K, I, L* that *K* lies on the line *BC*, and $KB = m$, $KI = x$, $KI \,||\, AB$, and *I* lies on the line *BK* and (see Fig. 12)

$$IK : IL :: n : a.$$

and $KL = \frac{n}{z}x$. When the triangle ΔIKL is given, the following proportion is also given

$$KL : IL :: n : a.$$

Hence (by the same magic trick applied all throughout *La Géométrie*),[27]

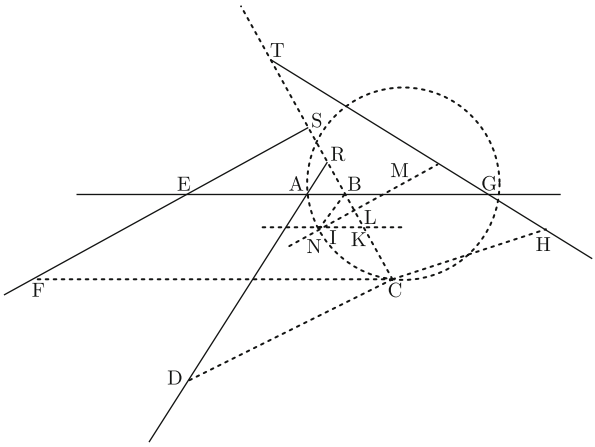
$$IL = \frac{a}{z}x.$$

Given *LC* is not equal zero "the point C always lies on one of the three conic sections, or on a circle" (Descartes 1637a, 328), namely when

[26] Bos (Bos 2001) advocates the thesis that Descartes' square root should be interpreted geometrically rather than via some definition, e.g., our definition (2). While it is easy to read the formula $\sqrt{\frac{1}{4}a^2 + b^2}$ in this way (see Bos 2001, 300, 305), the formula $mm + ox - \frac{p}{m}xx$, as it occurs in (11), has no geometrical interpretation – we can only state that it represents a line segment.

[27] Bos (Bos 2001), p. 322, processes these proportions as if they were just fractions.

Fig. 12 *La Géométrie,* p. 334



$$y = m - \frac{n}{z}x + \sqrt{mm + ox},$$

then the *locus* is a parabola; when

$$y = m - \frac{n}{z}x + \sqrt{mm + ox + \frac{p}{m}xx},$$

it is a hyperbola; and when

$$y = m - \frac{n}{z}x + \sqrt{mm + ox - \frac{p}{m}xx},$$

it is an ellipse; when moreover, $\angle \mathrm{I}LC = \frac{\pi}{2}$ and $a^2m = pz^2$, then the *locus* is a circle.

Descartes ends this lengthy argument with an example that refers to the circle and "explains given quantities by numbers" (see Descartes 1637a, 333–334).

7.3 Numerical Example

Descartes' numerical explanation refers to the solution represented in Fig. 12. At first, he assumes

$$EA = 3, AG = 5, AB = BR, BS = \frac{1}{2}BE, GB = BT,$$
$$CD = \frac{3}{2}CR, CF = 2CS, CH = \frac{2}{3}CT, \angle ABR = \frac{\pi}{3}$$

Under these assumptions, the equation of the *locus* is as follows:

$$yy = 2y - xy + 5x - xx,$$

and

$$y = 1 - \frac{1}{2}x + \sqrt{1 + 4x - \frac{3}{4}xx}.$$

Descartes easily finds that $n : z = \frac{1}{2}$, and "KL must be equal to one-half KI." As a result, the triangle ΔIKL is a right angle triangle. Since $KL = \frac{x}{2}$, then $IL = \sqrt{x^2 - \frac{1}{4}x^2} = x\sqrt{\frac{3}{4}}$. By putting these results in the proportion $IK : IL :: z : a$, he obtains $x : x\sqrt{\frac{3}{4}} :: z : a$.

Assuming "the quantity represented by z above is 1," he gets

$$a = \sqrt{\frac{3}{4}}, m = 1, o = 4, p = \frac{3}{4}.$$

Hence $IM = \sqrt{\frac{16}{3}}$, and $NM = \sqrt{\frac{19}{3}}$. "And since *aam* (which is $\frac{3}{4}$) is equal to *pzz*, and the angle ILC is the right angle, it follows that the curve *NC* is the circle" (Descartes 1637a, 333–334).

7.4 Magnitudes, Numbers, and Quantities Versus Elements of an Ordered Field

In the sixteenth century, the Greek μέγεθος was interpreted by the Latin *magnitudo* or *quantity*. Yet the other term was ambiguous as it could mean a line segment or its measure.[28] In mathematical practice, numbers were assigned to line segments, and then they were terms in expressions derived on a geometric basis.[29] Thus, for example, the term $\sqrt{101}$ stood for the hypotenuse of a triangle with legs 10 and 1.[30]

[28] The ambiguity of *quantity* could be traced back to Aristotle's definition (*Categories* 6, 4b20–25), where quantities (ποσόν) are exemplified by numbers and line segments.

[29] See (Oaks 2018), § 3.7.

[30] Malet (Malet 2006) studies the conceptual shift between numbers and magnitudes based on the sixteenth- and seventeenth-century editions of the *Elements*. He specifically observes: "not only was the neat and consistent separation between the Euclidean notions of numbers and magnitudes preserved in Latin medieval translations [. . .], but these notions were still regularly taught in the major schools of Western Europe in the second half of the fifteenth century. By the second half of the seventeenth century, however, the distinction between the classical notions of (natural) numbers and continuous geometrical magnitudes was largely gone, as were the notions themselves" (Malet 2006, 64–65). While Malet explores bridging the conceptual gulf between numbers and magnitudes, we explore basically the same issue, however, from the perspective of mathematical techniques.

It was also a common sixteenth-century practice to conclude geometric propositions with numerical examples. Viete's practice was even more radical: "All numbers with which Viete operates in his works are the measures of geometric magnitudes. They can be any positive number that arises in geometric calculation, including fractions and irrational roots, and they are never zero, negative, or complex" (Oaks 2018, 268).

It was also a common seventeenth-century practice to turn proportion $a : b :: c : d$ into the equation $ad = bc$. Then it was interpreted via proposition VI.16 of the *Elements* as an equality of rectangles with sides *a, d,* and *b, c.* Viète, again, applied it "regardless of the dimensions of the related magnitudes" (Oaks 2018, 247), and it is considered to be a bold achievement. Bos identifies a pre-Cartesian author who applied a unit line in multiplication of line segments.[31] All these findings may raise doubts whether is there a germ of novelty in *La Géométrie*?

In Descartes' numerical example, the really striking idea is the assumption $z = 1$. If z can be 1, what is the reason for Euclidean proportion at all. And in fact, that is how Newton, a dedicated student of Descartes' geometry, defines number:

"By Number we understand not so much a Multitude of Unites, as the abstracted Ratio of any Quantity to another Quantity of the same kind which we take for Unity. [Number] is threefold: integers, fracted, and surd, to which last Unity is incommensurable" (Newton 1720, 2).

Let us note also that when Descartes applies surds like $\sqrt{3}$ – in the above numerical example but also as coefficients of polynomials – they do not need to be interpreted as a hypotenuse of a triangle. His algebra of line segments provides a coherent foundation for multiplication, division, and square roots for numbers and line segments. In general, it provides a framework for processing both numerical and geometrical terms. Another Newton's definition embodies that idea:

"For by a Square, or Rectangle, or a Quantity of two Dimensions, we do not always understand a surface, but most commonly a Quantity of some other Kind, and very often a Line which is produced by the Multiplication of two other lines" (Newton 1720, 5).

And indeed, a multiplication, division, and square root of line segments is explained further based on a diagram alike Descartes' Fig. 1 (see Newton 1720, 5–7).

There is also an ongoing debate, whether Descartes applied arithmetic operations to line segments, or geometric operations to numbers. That controversy rests on a contrast between numbers and magnitudes. From the perspective of an ordered field, Descartes developed a system of processing formulas which combines numbers and line segments, both positive and negative.[32]

[31] See (Bos 2001), 154–156.

[32] Schubring (Schubring 2005) reaches another conclusion, namely: "A separation of the concept of number from the concept of quantity was not realized here [in *La Géométrie*], and hence no fusion of positive and negative numbers to the unified area of integers" (Schubring 2005, 49). This statement assumes, and in fact it is the core idea of (Schubring 2005), that a kind of separation of numbers from line segments is a condition sine qua non for the concept of negative numbers. We argue, on the contrary, that Descartes developed a unified framework for numbers and line segments (quantities), and within it he introduced negative elements.

At the end of the nineteenth century mathematicians sought to formalize the Greek concept, as they believed, of magnitude. In these studies, the term magnitude was a synonymous with quantity (English *magnitude* and *quantity,* French *grandeur* and *quantitaté,* and German *Grösse* and *Quantität*). From the mathematical perspective, all these tries shared the common core: magnitude is an Archimedean, totally ordered semigroup.[33] When Hilbert (Hilbert 1900, 2015) introduced a definition of ordered field and axioms for real numbers, that research program faded away. One may view Descartes' *La Géeoméetrie* as its starting point.

8 Ancient Greek Numerical Practice Based on Geometry

The practice of basing numerical analysis on geometrical results mentioned above dates back to ancient Greek mathematics. Archimedes' *Measurement of a circle,* derivation of the size of chords in Ptolemy's *Almagest,* or Heron's *Metrica* provide model examples of that tradition. In the next section, we will analyze proposition I.8 of *Metrica* to illustrate in what sense a numerical analysis was based on geometry and how Descartes' field of line segments enabled to combine that kind of numerical practice and geometrical studies. To this end we need to cover basics of Euclid's arithmetic.[34]

8.1 Euclidean Arithmetic and Beyond

Euclid's *Elements* books VII to IX provide foundations for the ancient Greek number theory. Number (ἀριθμός) means the modern integer greater than 1. Zero does not occur in the *Elements,* while 1 is the so-called monad (μονάς). The first three definitions of book VII clarify the relation between monads and numbers. They read:

"A unit (μονάς) is (that) according to which each existing (thing) is said (to be) one. And a number (is) a multitude (πλῆθος) composed of units. A number is part of a number, the lesser of the greater [n < m], when it measures the greater."

We can formalize definition VII.2 as follows:

$$n = \underbrace{1 + \ldots + 1}_{n\ times}.$$

The term *n measures m* means that for some $k \in \mathbb{N}$ the equality holds

$$m = kn = \underbrace{n + \ldots + n}_{k\ times}.$$

[33] See (Błaszczyk and Fila 2020), § 6.

[34] Another way of studying arithmetic was developed by Diophantus (Christianidis and Oaks 2021). It is rather unrelated to the issues discussed here.

By multiplication of numbers as introduced by definition VII.15, we formalize

$$n \cdot m = \underbrace{m + \ldots + m}_{n \text{ times}}.$$

It can be shown[35] that Euclid's numbers form a structure $(A, +, \cdot, <)$, where addition and relation *greater than* are primitive notions characterized by axioms E1-E3, as formalized in Sect. 2 above.

Next to these common operations, in definition VII.20 Euclid introduces a proportion of numbers:

"Numbers are proportional when the first is the same multiple, or the same part, or the same parts, of the second that the third (is) of the fourth."

We formalize it by

$$m : n :: k : l \Leftrightarrow \exists p(pn = m, pl = k) \vee \exists p(pm = n, pk = l) \vee$$
$$\vee(\exists u_1, u_2)\,(\exists p, q)(m = pu_1, n = qu_1, k = pu_2, l = qu_2).$$

Contrary to the theory of magnitudes, the proportion of numbers does not refer to the relation *greater than.* There is also no counterpart of definition V.7 in Euclid's theory of numbers. Finally, axiom E5 does not hold in the domain of numbers.

In book X of the *Elements,* numbers and magnitudes, in particular their proportions, are studied within the same but unspecified framework.

In the late sixteenth and throughout the seventeenth century, there were tries to find a common ground for definitions V.5 and VII.20. Palmieri (Palmieri 2001) studies in great detail that kind of research carried out by Clavius and Galileo. They both found definition V.5 problematic as it refereed to infinitely many cases – $(\forall m, n)\,(\ldots)$ in our formalization.[36] For Clavius, it was a problem, say, in the foundations of mathematics.[37] For Galileo it also concerned his studies in natural

[35] See P. Błaszczyk, M. Fila, *On Bolzano and Greek concept of continuity* in this *Handbook.*

[36] It is worth noticing that Clavius' reading of Euclid's definition V.5 (see Palmieri 2001, 561) perfectly fits our formalization, as presented in x 2 above, except quantifiers. Note also that when Euclid applies def. V.5 in proposition VI.1, then, instead of $(\forall m, n)\,(\ldots)$, he simply takes $m = n = 3$. Indeed, it is his standard mode of operation whenever, from the modern perspective, the universal quantifier is involved.

[37] Calvius, for example, in a comment to the definition of ratio (Euclid 2007, def. V.3), portrays numbers on a par with lines and other magnitudes. Then he seeks to prove an equivalence of definitions V.5 and VII.20. Here is a sample of his argumentation: if $D \cdot E = C \cdot F$, then, by VII.19, it gives the proportion of numbers, $D/C :: F/E$, and by inversion, the desired proportion $C/D :: E/F$ obtains; see (Palmieri 2001), 558, 567, respectively. Thus, although we stated above that the multiplication of numbers is commutative, it was not that obvious in the ancient and early modern arithmetical practice.

Here is a sample of his argumentation: if $D \cdot E = C \cdot F$, then, by VII.19, it gives the proportion of numbers, $D/C :: F/E$, and by inversion, the desired proportion $C/D :: E/F$ obtains; see (Palmieri 2001), 558, 567, respectively. Thus, although we stated above that the multiplication of numbers is commutative, it was not that obvious in the ancient and early modern arithmetical practice.

science, where he often referred to the very definition of proportion.[38] Whatever motivations, no one even tried to question results of book V. More importantly, although there were other attempts to redefine the ancient proportion in the seventeenth century, none of them yielded new propositions.[39]

In general, Descartes arithmetic turned out to be more successful foundation of mathematics and natural science than a theory of proportion. And the reason is simple: It enables to bring together within a structure of an ordered field both geometrical and arithmetical knowledge. We can appreciate it by comparing Heron's proof of the formula for the area of a triangle and its modern counterparts.

8.2 Heron's Formula for the Area of a Triangle

Heron's *Metrica* (Schöone 1903) is a study on measurement of plane figures and solids. It applies a unit square (μονάς) to approximate areas of triangles, polygons, ellipses, and circles. In calculations, lines are considered multiples of a unit line (μονάς), and they are represented by natural numbers. Then, for example, through the Pythagorean theorem, Heron determines the square of a hypotenuse, and, when it is needed, approximates its square root.

In propositions I.5–6, and I.8, Heron determines numerical area (έμβαδόν) of a triangle when its sides (in fact, lengths measured by integers) are given. In I.5–6, he applies Euclid's version of the law of cosines, namely II.12–13. Regarding an acute angle triangle, Euclid's II.13 brings in the following equation (see Fig. 13):

$$AC^2, 2BC.BD = AB^2, BC^2,$$

where AC^2 stands for the square on AC etc., and $BC.BD$ – for the rectangle contained by BD and BC.[40]

Now, Heron substitutes numbers for names of line segments, namely $AB := 13$, $BC = 14$, $AC = 15$ (of μονάδων), and as a result obtains $BD = 5$. In the numerical version, however, the above formula turns into the following one

$$AC \cdot AC + 2BC \cdot BD = AB \cdot AB + BC \cdot BC.$$

In the next step, by the *Elements* I.47, Heron determines $AD = 12$, then $BC \cdot AD = 168$.

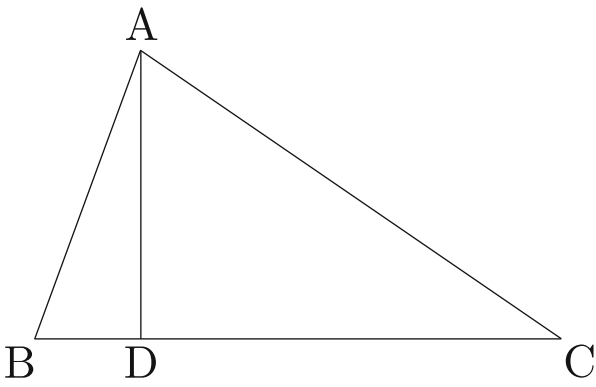
Finally, he finds that the triangle ABC is 84 of μονάδων.

[38] Galileo sought to bypass the reference to infinitely many case in definition V.5 by founding proportion on definition V.7, namely (in our stylization) $A/B :: C/D$ iff it is not the case that $A/B < C/D$, and $A/B > C/D$; see (Palmieri 2001), 576.

[39] See (Giusti 1993).

[40] For a detailed analysis of Euclid's book II, see (Błaszczyk 2020).

Fig. 13 Heron, Metrica, I.5



In I.7 – through a reference to X.54, as Taisbak (Taisbak 2014) observes – Heron states a numerical identity to the effect $\sqrt{AB^2 \cdot CD^2} = AB \cdot CD$. This proposition is not accompanying by any diagram.[41]

In I.8, Heron derives a formula for the area of a triangle without determining its height when its three sides are given.

The thesis of the proposition reads: "Let the triangle *ABC* be given, and let each AB, *BC*, *CA* be given. To find its area (ἐμβαδόν)."

At first, Heron assumes that sides of a triangle ΔABC are 7, 8, and 9 (see Fig. 14). Then he calculates $s = \frac{7+8+9}{2}$, and finds that $s(s–7)(s-8)(s-9) = 720$. By taking the squares of some guessed numbers (greater or smaller than 720), he arrives at the conclusion that $\sqrt{720}$ is about (ἔγγιστα) $26\frac{1}{2} + \frac{1}{3}$.

Referring to I.5, and I.6, Heron observes that instead of finding the height of the triangle, he can provide a "general method" of determining the area of a triangle. The proof starts with an observation that $\Delta ABC = GC.EH$, where $GC = \frac{1}{2} \times (AB + AC + BC)$, and EH is a radius of a circle inscribed in the triangle ΔABC – in our notation, s and r, respectively. To simplify the notation further, let Δ stand for ΔABC.[42] Thus, $\Delta = rs$. Then comes the crucial statements:

[1]. that between CG, EH is the side (πλευρά) of that on CG and that on EH, thus
[2]. (Artin and Schreier 1926) the area (ἐμβαδόν) of the triangle ABC multiplied (γενόμενον) by itself is equal to the square on CG by that on EH.[43]

[41] Note that in Descartes' system, $\sqrt{a^2} = a$ no matter if a is a number or a line segment. See formula (1), in Sect. 3 above.

[42] For the same reasons we apply fractions rather than symbol of proportion; moreover, symbol s^2 stands for a square on s, and rs – for a rectangle between r, s. We also add references to the *Elements* to underline a reliance of this proof on the *Elements* V.

[43] The term γενόμενον is applied on regular basis in the *Elements*, books VII, IX, i.e., in arithmetic context. On the other hand, the term πλευρά is applied both in geometrical and arithmetical contexts.

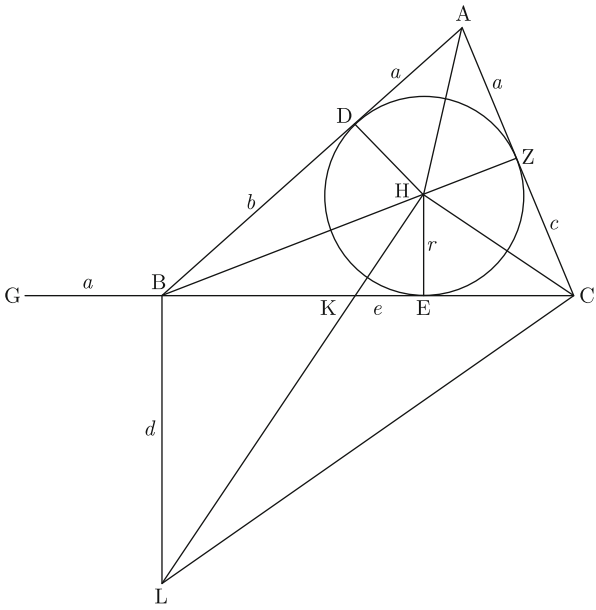


Fig. 14 Heron, *Metrica,* I.8 (modified: lower case letters added)

We can formalize them as follows[44]

$$[1]\, sr = \sqrt{s^2 r^2}, \quad [2]\, \Delta\Delta = s^2 r^2.$$

The next step brings in basic geometrical insights. Heron constructs right angle triangles ΔLHC and ΔLBC, and observes that since they share the hypotenuse LC, the quadrilateral $BHCL$ is inscribed in a circle. Thus, via *Elements,* III.22, $\angle BLC$, $\angle BHC = \pi$. It follows from the construction that $\angle DHA$, $\angle BHC = \pi$. Therefore, $\angle BLC = \angle DHA$. It entails the following proportions[45]:

$$\begin{aligned} \Delta BLC \sim \Delta DHA \quad &\rightarrow \quad \frac{b+c}{d} = \frac{a}{r} \\ &\overrightarrow{V.16} \quad \frac{b+c}{a} = \frac{d}{r} \end{aligned}$$

Further geometrical analysis yields another proportions:

[44] Shöne (Schöone 1903) and Thomas (Thomas 1957) instead of a translation of this passage provide formulas (in Greek letters): $GC \times EH = \sqrt{GC^2 \times EH^2}$, $ABC^2 = GC^2 \times EH^2$. Acerbi and Vitrac translate it literally: "mais le [rectangle contenu] par ΓΘ, EH est un [côté] du carré sur ΓΘ par celui sur EH; il en résultera donc quel'aire du triangle ABG multipliée par elle-même est égale au [carré] sur GJ par celui sur EH" ([Acerbi and Vitrac 2014], 166).

[45] We assume, $BE = BD = b$, $EC = EZ = c$, $DA = AZ = a$, $KE = e$, $BL = d$, etc., see Fig. 14.

$$\begin{array}{lll} \Delta BKL \sim \Delta EKH & \rightarrow & \dfrac{d}{r} = \dfrac{b-e}{e} \\ \dfrac{b+c}{a} = \dfrac{b-e}{e} & \overrightarrow{V.18} & \dfrac{a+b+c}{a} = \dfrac{b}{e} \\ \dfrac{s}{a} = \dfrac{b}{e} & \overrightarrow{V.I.1} & \dfrac{s^2}{sa} = \dfrac{bc}{ec} \\ HE \perp KC, \angle KHC = \pi/2 & \overrightarrow{V.I.8,16} & ec = r^2 \\ & \rightarrow & s^2r^2 = sabc. \end{array}$$

Finally, to show that the resulting formula depends only on given sides, Heron observes that

$$a = s - (b - c), b = s - (a + c), c = s - (a + b).$$

The proof of I.8 is followed by another numerical example in which Heron shows that the area of a triangle with sides 12, 13, 14 is 84.

The numerical context in Heron's propositions in obvious. It is also obvious that to get these results Heron has to root his arguments in geometry. Yet finally, when geometry is helpless, he adopts a numerical interpretation. Thus, while the proportion $\frac{s^2}{sa} = \frac{bc}{ec}$ has a geometrical sens, the formula $s^2r^2 = sabc$, or $\Delta = \sqrt{sabc}$, can be interpreted only numerically. However, in Descartes' framework, formulas s^2r^2 or $\sqrt{sabc}$, whether s,r,a,b,c are numbers, or line segments are just as meaningful.

For comparison sake, let us go back to Fig. 13 and adopt a modern notation, namely $AD = h$, $BC = a$, $AC = b$, $AB = c$, $BD = d$. Contrary to Heron's subtle arguments, modern proofs apply just basic laws, yet in algebraic stylization, namely, the area of the triangle equals to $\frac{1}{2}ab \sin \angle A$, or $\frac{1}{2}ah$, the cosine law takes the form $b^2 = a^2 + c^2 - 2\,ac \cos \angle B$, and the Pythagorean theorem is interpreted as $h^2 = c^2 - d^2$, or $\sin^2 \angle B + \cos^2 \angle B = 1$. Then, since the desired result is known, these formulas are processed according to the rules of an ordered field without any concern of their geometric meaning.[46] Although, a, b, etc., stand for real numbers, in the context of Euclidean geometry, we do not exploit the full power of the so-called completeness axiom – it just guarantees the existence of square roots.

In sum, modern proofs of the Heron's formula can be also derived in Descartes's field of line segments. In fact, they mimic the way Descartes processed formulas in *La Géométrie*, despite trigonometric identities, which in that context represent Euclid's propositions in a disguise.

9 Euclidean Versus Descartean Plane

Euclid developed geometry in the so-called synthetic fashion. Descartes adopted completely new method and his system is governed by technical issues rather than axiomatic meditations. In the nineteenth century, the name *analytic geometry* was

[46] Variety of proofs can be easily found in the Internet, see for example http://cut-the-knot.org/

coined for that way of studying algebraic curves. In the above sections, we compared basic techniques of Euclid's and Descartes' geometry, that is the theory of proportions and the arithmetic of line segments. In this section, we adopt a more abstract approach and aim to correlate these techniques with a characteristic of Euclidean and Descartean plane.[47] To this end, we reconsider Euclid's and Descartes' geometry on the so-called Cartesian plane $\mathbb{F} \times \mathbb{F}$ over an ordered field $\mathcal{F} = (\mathbb{F}, +, \cdot, 0, 1, <)$. Within that framework, the characteristic of a plane could be reduced to a property of the field $\mathcal{F}$.

Thus, a plane $\mathbb{F} \times \mathbb{F}$ is Euclidean *iff* the field $\mathcal{F}$ is closed under the square root operation. A plane characterized by this condition satisfies both circle-circle and circle-line intersection property.[48] Thus, that sole algebraic condition guarantees that straightedge and compass constructions are realizable on the plane $\mathbb{F} \times \mathbb{F}$. That is how we identify Euclid's geometry as developed in books I-IV. Regarding that part of the *Elements,* the field $\mathcal{F}$ could be Archimedean or non-Archimedean. Since Euclid's theory of similar figures requires proportions founded on axioms E1-E5, the study of that part of the *Elements* requires the field $\mathcal{F}$ to be Archimedean.[49]

Descartes' field of line segments is explicitly closed under the square root operation. But he added yet another condition, namely:

"Now to treat all the curves which I mean to introduce here, only one additional assumption is necessary, namely, two or more lines can be moved, one upon the other, determining by their intersections other curves" (Descartes 1637a, 316).

What does he mean in this sentence? Going back to Fig. 9, when we put a parabola in place of the line CNK, the resulting curve will be the so-called cubic parabola.[50] When in place of that parabola we put the cubic parabola, we get another line of a higher degree. Descartes believed that the class of curves generated by iterations of that process enables one to construct roots of a polynomial of any degree. Hence, we can identify his *additional assumption* as the curve-line intersection property, where curve means an algebraic curve, i.e., a curve defined by a polynomial equation $\psi(x, y) = 0$. We can simplify this geometrical criteria to the condition of the existence of roots of polynomials of odd degree, since it provides a neat property of the field $\mathcal{F}$.

Interestingly, when, in book III of *Geometry,* Descartes develops the first ever theory of polynomials, he observes that n-th degree polynomial $\varphi(x)$ has n roots:

"Every equation can have as many distinct roots (values of the unknown quantity) as the number of dimensions of the unknown quantity in the equation" (Descartes 1637a, 372). A few pages away, he is even more precise, as he writes.

"Neither the true nor the false roots are always real (*reelles*); sometimes they are imaginary (*imaginery*), that is, while we can always conceive of as many roots for

[47] Since the term *Cartesian plane* has the well-established meaning in mathematics, in this section, we choose a bit awkward term *Descartean plane* to emphasize the historical context.

[48] See (Hartshorne 2000), 144.

[49] There are of course Archimedean fields closed under the square root operation other then (i.e., *smaller*) the field of real numbers, as well as non-Archimedean fields closed under the square root operation.

[50] See (Descartes 1637a), 337.

each equation as I have already assigned, yet there is not always a definite quantity corresponding to each root so conceived of. Thus, while we may conceive of the equation $x^3 - 6xx + 13x - 10 = 0$ as having three roots, yet there is only one real root, 2, while the other two, however we may increase, diminish, or multiply them in accordance with the rules just laid down, remain always imaginary" (Descartes 1637a, 380).

We can factorize the discussed polynomial as follows:

$$x^3 - 6x^2 + 13x - 10 = (x-2)\left(x^2 - 4x + 5\right) = (x-2)(x-2-i)(x-2-i).$$

Next to the above remarks, there are other really insightful comments concerning polynomials.[51]

On this basis, we say that the plane $\mathbb{F} \times \mathbb{F}$ is Descartean *iff* the field $\mathcal{F}$ is real closed, i.e., (1) is closed under the square root operation, and (2) every polynomial of odd degree has a root.

A real closed field could be, again, Archimedean or non-Archimedean.[52]

Thus, the assumption that not only circles but other curves intersect straight lines, results in different characteristic of Euclidean and Descartean plane.[53] All in all, Descartes' field of line segments $(\mathbb{F}, +, \cdot, 0, 1, <)$ is a real closed field.

Viewed from the foundational perspective, the Archimedean axiom is a necessary condition of Descartes' arithmetic, as explained in Sects. 2.1 and 4. Yet, neither Descartes nor his followers, specifically Newton and Euler, paid attention to that issue. They just processed formulas in an ordered field.[54]

10 Summary

Our final conclusion that in *La Geométrie* line segments form a real closed field is based both on Descartes explicit statements and implicit rules revealed by studying the way he transforms proportions, algebraic terms, and polynomials, that is, on his mathematical practice. Thus, Descartes explicitly introduces operations on line segments: multiplication, division, and the square root. Yet, his transformation of Euclidean proportion into the equality of line segments, as encoded in the rule (ED), is implicit. Definitions (2) emphasize the dependence on his algebra of Euclidean proportions. From that stage on, the algebra of line segments develops by its own

[51] To name the most spectacular: (1) the number of positive roots is at most the number of sign changes in the sequence of polynomial's coefficients, (2) roots of a polynomial are bounded by a number determined by polynomial's coefficients.

[52] There are of course Archimedean real closed fields other than (i.e., *smaller*) the field of real numbers.

[53] Cf. (Panza 2011)

[54] Geometry over a real closed field is complete and decidable, while over a field closed under the square root is undecidable (see Ziegler 1976). One may interpret these meta-mathematical results as reaffirming optimism concerning new method voiced by Descartes at the end of book I. Yet, it looks a bit different when we consider his actual methods. Our skepticism, in the first place, concerns feasibility of his algorithm for finding roots of polynomials.

logic. While transforming algebraic terms, Descartes implicitly applies laws of an ordered field exemplified in the formulas (1). In book III, he explicitly introduces zero and negative line segments. His theory of polynomials, specifically factorization of polynomials, as well as rules (3) and (4), guarantees mathematical sense for these concepts. Finally, his explicit declaration concerning intersections of algebraic curves allowed us to characterize the structure of line segments as a real closed field.

Acknowledgments I am grateful to John T. Baldwin, Kazimierz Mrówka, Marco Panza, and Benjamin Wilck for helpful comments.

Abstract

Until recently Euler was seen essentially as a mathematician than a physicist (modern meaning). After all, more than 60% of his work deals with pure mathematics, and even those whose object is mechanics and astronomy contain many sections that can be classified as mathematics. Today Euler's role as a physicist, especially as a scholar of mechanics, is re-evaluated. One of the most prolific scientific writers, Euler treated all the themes of mathematics and physics, from astronomy to optics, from electricity to magnetism, and from hydraulics to mechanics to music, leaving an indelible mark in all sectors. He also wrote many

pages of philosophy of nature, still of interest today because written with the sober language of the mathematician. As a matter of fact, it is impossible to distinguish the various facets of the polymath Euler. The present chapter focuses on mechanics, with particular attention to the epistemological, metaphysical, and natural philosophy aspects. The texts of Euler largely collected in his *Opera omnia*, still in progress, are analyzed avoiding as much as possible the use of glasses colored by modern concepts of epistemology. What is considered important has been to render his ideas clear to a modern reader. A particular attention has been devoted to the paper *Anleitung zur Naturlehre* of 1750, published only posthumously in 1862.

1 Introduction

Leonhard Euler (1707–1783), born in Basel, the first child of Paul Euler and Margaretha (née Brucker), spent his beginning youth not in Basel but in the nearby Swiss countryside Riehen. (Over time the Euler family name has had a variety of spellings, with Öwler and Äweler in the fourteenth and fifteenth centuries and Öwbler, Ewbler, and Ouwler in the sixteenth.) His parents were his first teachers. Margaretha is thought to have instructed him in beginning reading. His father gave an elementary education in mathematics. Like his teacher Jakob Bernoulli, Paul Euler taught his young son mathematics not as an isolated discipline but as underlying all natural knowledge, interrelated with other fields.

Euler, who required instructional preparation completed, was sent by his parents to Basel, perhaps as early as the age of eight. By the second decade of the 1700s, Basel was no longer in its golden period; nonetheless the presence of Jakob and Johann Bernoulli made it a center for scientific and mathematical research.

In Euler's day schoolboys were sometimes beaten or knocked about until they bled. At other times the teacher might find himself dragged by the hair by an enraged father making an unannounced visit to the class. There is no reason to suppose that Euler's intelligence saved him from routine indignities and brutalities.

In 1715 Paul Euler hired as a private tutor Johannes Burckhardt (1691–1743), a young theologian with a tolerable background in mathematics. At the time Burckhardt was supporting Johann Bernoulli in arguments with Brook Taylor and other members of the Royal society of London over which was superior, Leibniz's differential calculus or Newton's.

After completing his gymnasium education in 1720, Leonhard registered at the University of Basel for courses in the philosophical faculty, which covered fields of learning outside recognized professions. It was the equivalent of the modern secondary school. The philosophical faculty imparted a general education before a student chose a specialty for a higher degree. Through hard work and an astonishing

memory, Euler mastered all of his subjects. During his first 2 years, he was enrolled in Johann Bernoulli's class for beginners in geometry as well as practical and theoretical arithmetic.

Euler spent 2 years earning his *prima laurea*, roughly equivalent to a bachelor's degree, receiving it in 1722 at the age of 15 after presenting the *ad lectiones publicas*, his undergraduate thesis, *De temperantia*, *extolling moderation*. In conversations and intellectual debates, Euler began to display to a wider public his substantial learning and his command of Latin. While he advanced rapidly in lower level mathematics courses, Euler did not however quickly gain the attention of his teacher Johann Bernoulli.

In the autumn of 1723, Euler passed the examination of the philosophical faculty for the Master of Arts degree and officially received it on 8 June 1724 at the age of 17. At the graduation session on that day, Euler gave a public lecture in Latin comparing the natural philosophy of René Descartes with that of Isaac Newton and indicating the consequences of each. It was probably in consultation with Burckhardt and Johann Bernoulli that he had chosen this important and timely topic.

Euler's increasing attention toward mathematics and natural philosophy did not please his father, who obliged him to register in the theology faculty in 1723 in preparation for taking holy orders. He felt fortunate to continue Saturday meetings with the stern Johann Bernoulli. As Leibniz was dead and Newton old and less active, Bernoulli was since 1707 the leading mathematical preceptor in all of Europe. While likely concerned about employment for his genial son, Paul Euler accepted a Johann Bernoulli's request for Euler's shift out of theology.

Euler's friend and classmate Johann II, the youngest Bernoulli son, had tried gain him access to a possible tutorial with the father. But Johann Bernoulli was busy, and flatly refused to give Euler private lessons. Instead he advised him to start reading some more difficult mathematical books and work through them as diligently as he could, and if he came across some obstacle or difficulty, he could visit him every Saturday afternoon.

All suggests that Euler examined such classics as the second edition of Copernicus's *De revolutionibus orbium coelestium* from 1566 as well as Kepler's *Astronomia nova* of 1610 and Galileo's *Dialogo sopra i due massimi sistemi del mondo* published in 1632. Euler's master's lecture shows that he was studying Descartes's *Principia philosophiae* and *La géométrie*. He possibly also read Rohault's Cartesian masterful *Traité de physique*, a major physics text of the late seventeenth century, which appeared in 1671.

The interests of Euler's teacher make it probable that he read a range of works relating to the new calculus and its applications, beginning with the *Analyse des infiniment petits pour l'intelligence des lignes courbes* published in 1696 in Paris, attributed to de L'Hôpital. Euler possibly examined two texts of Varignon, a correspondent, disciple, and close friend of Johann Bernoulli: the *Projet d'une nouvelle méchanique*, published in 1687, and *Nouvelles conjectures sur la pesanteur* of 1690. Varignon's two-volume *Nouvelle mécanique ou statique* and *Éclaircissemens sur l'analyse des infiniment petits*, both from 1725, may also have been available. Euler must have studied Jakob Bernoulli's articles on the theory of infinite series,

published from 1682 to 1704 and reprinted in 1713; his *Ars conjectandi* on probability, with a preface by Nikolaus I, published posthumously in 1713; and Jakob Hermann's *Phoronomia, sive de viribus et motibus corporum solidorum et fluidorum* of 1716. Other books to which Euler referred to are John Wallis's *Arithmetica infinitorum* (1656) and Brook Taylor's *Methodus incrementorum directa et inversa* (1715). No confirming evidence exists on whether Euler saw Johann Bernoulli's pioneering articles for the Académie des sciences of Paris in 1718 on what would become the calculus of variations. (Most of the bibliographic information is drawn from Calinger (2016).)

Euler was called to the Academia scientiarum imperialis petropolitanae of St. Petersburg by his friend Daniel Bernoulli in 1727. He remained there until 1741 to reach the Académie royales des sciences et belles lettres de Berlin. Here he had some problems with Frederick II that finally pushed him back to St. Petersburg in 1766 where he remained until his death in 1783, at the age of 78 and almost completely blind. One of the most prolific writers, among the greatest mathematicians of all time, Euler treated all the themes of physics, with an approach, however, more as a "mathematician" than an experimental physicist, from astronomy to optics, from electricity to magnetism, and from hydraulics to mechanics to music, leaving an indelible mark in all sectors. He also wrote many pages of philosophy of nature, still of interest today because written with the sober language of the mathematician. His writings, more than 20 books and pamphlets and about 800 papers, are collected in his *Opera omnia* (Euler 1911–2018). It remains to complete the correspondence, written in several languages. Most are in Latin and French and some in German and Russian (Euler also had competence in Italian, Spanish, Chinese, and Japanese). Despite his strong religiousness, Euler was an illuminist philosopher-scientist, and his faith in reason transpires in all his writings.

2 Philosophy of Nature

Since entered the University of Basel, Euler, as discussed just above, had been deeply interested in the studies of theology and natural philosophy, and only 17 he gave a lecture for his master's degree comparing the natural philosophies of Descartes and Newton.

Certainly he was not a professional philosopher, but he reflected at length on the classical themes of philosophy of nature. He was not interested in discussions of a metaphysical character, and even for that, he was generally hostile to the approach to the natural philosophy and mechanics of Leibniz's school, represented in his time by his colleague Christian Wolf (1679–1754). Studying Euler's philosophy is challenging not so much to understand his works on mechanics or physics (modern sense) but rather to see how natural philosophy was being transformed into the hands of mathematicians. It is indeed his mathematics that influenced his philosophy and not vice versa; in particular his research on Calculus influenced his conception of matter and space.

Euler's ideas about philosophy of nature are scattered everywhere. The natural reference is however to the *Anleitung zur naturlehre* (Euler 1862) of the 1750s, referred in the following as the *Anleitung*, and *Lettres à une princesse d'Allemagne* (Euler 1770–1774) of 1760s, referred in the following as *Lettres*. The *Anleitung* did not spread greatly, even because of his late publication. The *Letters* had instead a different fate. Michael Faraday (1791–1867), for instance, read the letters (Calinger 2016, p. 565, note 35) but not the *Anleitung* which was probably read by Bernhard Riemann (1826–1866) (Speiser 2010, p. 46).

Euler's philosophy of nature was generally well received, praised by Voltaire, for instance. According to Alexandre Koyré, the *Lettres* may be included among prominent Newtonian popularizations (Koyré 1965, p. 18). But also by Leibniz, even though here and there, Euler criticized his philosophy of nature. Euler had no particular reason to stand on one side or the other in the philosophical debates of the period though he had a profound estimate of Newton referring to him as the *Summus Neutonus*; not being a professional philosopher, he could limit himself to accepting those ideas that seemed closer to his sensitivity as a mathematician without looking deeply into their consistency.

It should be cited however a strong criticism by two scholars well connected with Euler, d'Alembert, and Lagrange. They judged him severely. Lagrange wrote to d'Alembert, "Our friend is a great analyst but quite poor a philosopher" (Lagrange 1867–1892, Vol. 13, p. 135). (Letter of Lagrange to d'Alembert, 16th June 1769.) D'Alembert replied indignant: "It is incredible that such a great genius as him on geometry and analysis is in metaphysics so inferior to the smallest schoolboy, not to say so flat and so absurd, and it is the case to say: *Non omnia eidem Dii dedere*" (Lagrange 1867–1892, Vol. 13, p. 148). (Letter of d'Alembert to Lagrange, 7th August 1769.)

2.1 Anleitung zur Naturlehre

The *Anleitung* has been received incomplete. The end of Chap. 5 and the beginning of Chap. 6 are missing (which probably occupied about seven pages). There are reasons to think that, even with these pages, the work could not be not complete and we can therefore ask why Euler did not finished it (Speiser 2010). In its current form, the book consists of 21 chapters that can be grouped: Chaps. 1–5, the role of natural philosophy and the main properties of matter; Chaps. 7–9, general introduction to the principles of mechanics; Chaps. 10–11, apparent motion, general rules of motions; Chaps. 12–18, the property of matter; Chaps. 15–18, possible forms of matter; Chap. 19, gravity; and Chaps. 20–21, principles of hydrostatics and hydrodynamics.

The opening of the *Anleitung* suggests a traditional treatise on natural philosophy or natural science, even of Aristotelian mold. According to Euler, natural science is a science that aims to explain the causes of changes that occur on material bodies. Wherever there is such a science, he continued, it is very incomplete, since it is able to state with certainty the causes of only very few changes. Moreover, changes are restricted to those occurring on inorganic or material bodies, thus distinguishing

natural science from the science of the mind, which aims to explain mental changes. Nothing is said about living beings (Euler 1862, Vol. 2, p. 449). All changes involving material bodies must arise from the essence and from the properties of the bodies themselves. What is common to all material bodies without exception is called a property of the bodies, and therefore all things not sharing this property are excluded from the domain of material bodies. The general properties of material bodies are those shared without exception. The essence of material bodies is a property that is not only shared by all material bodies but which is such that all things having this property must of necessity be considered to be material bodies. The best way for natural science to proceed is first to investigate the general properties, that is to say the essence of material bodies, and subsequently to subject all particular types of bodies to a similar examination (Euler 1862, Vol. 2, pp. 450–453).

Following the reading of the *Anleitung*, it is understood however that the causes and the properties of which Euler spook are those useful for a mathematical treatment of the philosophy of the nature, adopting a mechanistic approach in the broad sense; they are the extension (that is, the position and or a configuration), the mobility (velocity and acceleration), the persistence or inertia (mass), and the impenetrability (force, because forces are due to impenetrability). Euler wanted to found a coherent system, able to describe all the inorganic nature, starting only from some principles of mechanics and a few other hypotheses. Even Newton, another "mathematician" who wondered about the relationship between the philosophy of nature and mathematics, in some of his *Queries* (28–31) had sketched some ideas in this direction, but they remained only queries, that is, questions.

The first general property of material bodies is the extension, and anything that has no extension cannot be regarded as a material body. We are not only convinced by our experience that all material bodies that we know possess extension, but our concept incorporates extension in such a way that we can exclude all things without extension from the category of material bodies. It follows then that whatever can be said of extension per se can without exception also be said of material bodies. Everything with extension is divisible, and divisibility can be continued ad infinitum; therefore all material bodies are infinitely divisible (Euler 1862, Vol. 2, pp. 453–455). However Euler did not enter the question of the actual corpuscular (atoms) or continuum constitution of matter. What he could say is that one knows from experience that the actual subdivision of many material bodies can be carried out to an astonishing degree and that our tools and senses are too blunt to permit this subdivision to be carried even further. However he was not discussing what can actually be done but rather the merely the possibility of taking the subdivision even further.

For liquid matter Euler however denied the existence of atoms.

> A liquid matter cannot be formed from a number of small particles that are solid and hard, for whatever the shape and arrangement of the particles might be, for it is not possible that a pressure that acts at one location will propagate in all directions with equal force. (Euler 1862, Vol. 2, p. 526; Translation by Hirsch E.) (A1)

In the following a verbatim exposition of Euler argument is referred to. If one imagines these particles in the first place to have the shape of a cube and imagines

them to be arranged in an orderly manner on one another, then one sees easily that if the uppermost is pressed down by a force, the lowest will press on the ground with equal force, but sideways no force will be exerted; therefore if many such rows fill a vessel and a force presses on them from above, then the bottom of the vessel will experience an equal force, but the sides will experience none at all. If the particles were lying together in a disordered manner, then the pressure could also be propagated sideways, but it would not be the same in all directions. But what can be said of cubic particles is equally valid for all other shapes that involve corners, for which reason most natural scientists ascribe to the particles a spherical shape; but it is easy to show that from these, if they are assumed to be solid and hard, the main property of liquids cannot be obtained. It is only necessary to imagine a heap of spheres, arranged as is usual for cannon balls, to see that if they are pressed from above, they exert no force sideways, or that at least such a force would not be the same in all directions. In addition spheres that fill a vessel cannot lie together in such a regular manner that a great dissimilarity in their arrangement would not develop, that also would prevent a uniform pressure. If one assumes the spheres to be in uniform motion, then the pressure can change but cannot be maintained the same in all directions; and one would have to regard as extremely rare a case where the pressure was the same, remembering that this constitutes the essence of a liquid. One need only to consider that if three spheres lie in a straight line, the middle one can always be pushed sideways, whatever forces may be acting on the outer ones. On the various types of bodies (Euler 1862, Vol. 2, p. 526).

An important concept that Euler considered worthy to be exposed in his foundational text is what today is called potential energy or possibly work, to which he referred to as the *effectiveness* and to which he also assigned the name *effort des forces sollicitantes* (Euler 1757b, p. 287). (It must be said that Daniel Bernoulli in his work of 1750, *Remarques sur le principe de la conservation des forces vives pris dans un sens général*, introduced something like the effectiveness (Bernoulli 1750, p. 359).) The effectiveness of a force is the integral quantity that is found if one multiplies the force with the differential of the distance to which it pushes the body and then integrates. This concept is the more of the utmost importance, because (1) the sum of the effectiveness of all forces $\int Pdx + \int Qdy + \int Rdz$ always has the same magnitude – given by the increase of living force – if one had assumed three different planes, that is, in modern term, it is invariant with the change of coordinates. (2) The whole theory of equilibrium is based on it. For it can be shown that equilibrium cannot occur, if the sum of the effectivenesses is not a minimum or occasionally a maximum: "This marvelous theorem was first derived by the world renowned President de Maupertuis and is closely connected with the other general principle of frugality. From this we see at the very least that the effectiveness has a major influence on all motions that can be produced by forces, and that *it deserves to be given a special name* [emphasis added]" (Euler 1862, Vol. 2, p. 493; Translation by Hirsch E.). It also must be remarked however that Euler seems not to be conscious that he had to limit the nature of forces in his definition; only for what are now called conservative forces – for which the integrals appearing in the definition of effectiveness are independent of the path – Euler considerations has any meaning.

One more concept Euler maintained worth to be underlined is that of pressure into a fluid with its modern meaning, in English *stress* that is internal force per unit of surface. Until then pressure was simply a force of contact, the greater, the greater the surface. Euler introduced this new concept, maintaining ambiguously the same name *pressure* both for the global force and for the force per unit of surface. Because the pressure (traditional meaning), said Euler, depends on the magnitude of the area on which it acts, it is best if one represents it by a magnitude, the pressure (new meaning), which, when multiplied by an area, expresses the magnitude of the force that acts on the area, and the constancy of the pressure rests on the fact that this magnitude is constant. If we express by $aa \times k$ the force p, which acts on the base area $S = aa$, then the pressure on any area ff is:

$$\frac{ff}{aa} k \times aa = k \times ff$$

Therefore when k remains the same, then the pressure on the liquid matter is also the same (Euler 1862, Vol. 2, pp. 523–524). To picture this completely, Euler regarded k as a height and expressed the force acting on the area ff by the volume of a cylinder of base area ff and height k, since the volume of such a cylinder is $ff \times k$. This picture is very convenient, according to Euler, because forces are best represented by weights; for this one selects a uniform matter and says that the force, by which the area ff is pressed, is just the weight of such matter that fills the volume of the cylinder of volume $ff \times k$. Therefore such a height k gives us a clear understanding of the force that presses on the inner wall of the vessel filled with liquid matter, and that at the same time presses on all the parts within. For the larger or smaller this height is, the larger or smaller, in the same proportion, will be the force of the pressure (Euler 1862, Vol. 2, p. 524). A similar statement can also been found in the *Principes generaux the l'état d'équilibre des fluides* (Euler 1757a, pp. 5–7). Here he introduced the symbol p, still used today though limited to a pressure of external loads, instead of k to indicate stress. Euler also used his concept of stress for solids bodies (Capecchi 2001, p. 27).

It may seem strange that in a treatise dealing with general aspects, Euler had also found ample space to exquisitely technical aspects concerning the laws of hydrostatics and hydrodynamics (Chaps. 20–21). It must be kept in mind however that for Euler fluids were not only the ordinary ones, for example, water and air, but also the aether (see next sections) was a fluid and as such subjected to the laws of hydraulics. David Speiser, with a bit of whiggism, suggests that the advantage of Euler over Newton, in order to provide a unified theory of the various branches of physics, is the concept of the partial derivative equations, the mathematical basis of any field theory, a new tool, created by Euler himself and d'Alembert – and others – to formulate the mechanics of fluids. And it is thanks to this new mathematical tool that Euler was the first to imagine a unified field theory, an idea, and a hope that are at the center of the ambitions of physicists (Speiser 2010, p. 45).

In fact, according to Euler, all physical phenomena, with the possible exclusion of gravity (see below), can be reduced to the interactions of four scalar fields (the

densities and pressures of gross matter and aether) and two vector fields (the velocities of matter and aether), interconnected and governed by partial derivative equations. Seen as an attempt, Euler's way of proceeding with hydrodynamics is not very different from that used in modern physics to unify field theories, despite the present more in-depth knowledge of the structure of matter and the huge amount of accumulated empirical data. Even today, the basic differential equations of a field of physics, whose theory is known, are also considered as fundamental for other sectors, in which a theory is still lacking. In the case of Euler, the basic differential equations are those of hydrodynamics, and the radical hypothesis is that of an unique aether (Speiser 2010, p. 46). Despite the considerations of Speiser, which seem convincing, in the *Anititung* there is however no mention of the aethereal fluid, neither for what concerns electricity nor for what concerns magnetism. These topics that will be treated with plenty in the *Letters*.

2.2 Lettres à une princesse d'Allemagne

At the time of the publication of the *Letters*, Euler stood at the peak of his career. He was the director of the mathematics class (division) of the St. Petersburg Academy and a well-known mathematician. Although he sent the individual letters between 1760 and 1762, he had derived them from articles dating back to the 1720s. Thus, notwithstanding the didactic character, they offer an outline of his scientific ideas and the modifications occurring in them.

The letters, 234 in number (a thousand pages), originated from lessons delivered to the princess Charlotte Ludovica Luisa, a relative of Frederik II of Prussia, but were conceived more generally for young students. They met with prodigious success; by the turn of the nineteenth century, they had been translated from the original French into eight other languages: Russian, German, Dutch, Swedish, Italian, English, Spanish, and Danish. The numbering is different from edition to edition, here that of 1770–1774 edition is considered (Euler 1770–1774).

Euler's letters essentially concern philosophy of nature considered from different points of view, that of the traditional philosopher, with considerations of *physica generalis*, and that of the philosophers emerging at the time. It is not easy to group them by themes; it can be said that the first letters (about 140) have a more general character; the others are more technical and deal with current topics in physical research, among them at least 17 letters are devoted to electricity and nineteenth to magnetism.

Among the first letters, there are five dedicated to music (4–8). We are in a period in which the musical theory was undergoing somehow a revolution with Jean-Philippe Rameau (1683–1764) among the protagonists. Euler, only 24, had written an interesting paper on music, the *Tentamen novae theoriae musicae* of 1730–1731 (Euler 1739b), which was criticized by Rameau. The two "musicians" exchanged some letters about consonances in the 1750s (Calinger 2016, pp. 362–363).

Letters (17–44) follow that deal with optics. The first four of the theory of propagation of light with particular reference to Newton; only a nod is made at

Descartes; the others face problems of geometrical optics, of brightness and color of bodies, and also of the structure of the human eye. Euler compared the "emanation" (projectile) theory attributed to Newton with his vibrational theory, reported in particular in the *Nova theoria lucis* of 1744 (Euler 1746b). He did so without mentioning Huygens who had proposed a theory in which light spread in a medium as pulses. (About the difference between the conceptions of Euler and Newton and for a justification of the absence of the name of Huygens in Euler's writings of optics, see Hakfoort (1995).) According to Euler, to explain the nature of light and color, it must be admitted celestial spaces filled with a subtle matter, he called aether, a fluid matter like air but much thinner, nevertheless, with much greater elasticity (using a modern term, stiffer than air). And as in the air, the sound is propagated, so the light propagates in the aether (Euler 1770–1774, Vol. 1, Letter 19).

In the letters from 45 to 79, there are general considerations on mechanics. They speak of gravity in a general sense, of the law of universal gravitation, to conclude with the explanation of gravity that is associated with the elasticity of the aether, without however going into details. It is here that one sees that a mature Euler is not fully satisfied of his mechanical explanation of gravity. Indeed, in the letters 46 and 54, for instance, he wrote that "philosophers have warmly disputed, whether there actually exists a power which acts in an invisible manner upon bodies; or whether it be an internal quality inherent in the very nature of the bodies, and, like a natural instinct, constraining them to descend" (Euler 1770–1774, Vol. 1, Letter 46, p. 195), "On this question philosophers are divided. Same are of opinion that this phenomenon is analogous to impulsion; others maintain, with Newton, and the English in general, that is it consists in attraction" (Euler 1770–1774, Vol. 1, Letter 54, p. 230). Thus declaring his incapacity of a definitive choice.

Letters from 80 to 87 concern aspects of natural philosophy, bodies, and spirits. In the letter 76 Euler criticized Wolf's conceptions of dynamics. He did this by referring substantially to what he had already written in his *Gedancken von den Elementen der Cörper* of 1746 (Euler 1746b) (see below).

Letters 88 to 114 address issues of ethic, psychology, and logic. Particularly in the letters 103–105, the diagrams of Euler-Venn are used to explain some logical relations. It is true that the idea of representing graphically logical relationships was not completely new; this had happened in some treatises of the eighteenth century. But it was to Euler that the mathematician John Venn (1834–1923) referred to in his studies on logic more or less a century later. Some letters about epistemology follow, from which the influence of Descartes and Locke and perhaps even of Condillac transpire – without explicit reference to them – and letters of metaphysics in which Euler repeated the criticism toward Leibniz's monad system. From letter 133 onward, physical (modern sense) problems are addressed. In particular letters from 138 to 154 deal with electricity and letters from 169 to 186 with magnetism.

Apart from a summary of a paper by Aepinus (Euler 1761), the only left written works on the theory of electricity are on the *Letters*. This notwithstanding he considered electricity a very interesting field to be explored:

> The subject which I am now going to recommend to your attention almost terrifies me. The variety it presents is immense, and the enumeration of facts serves rather to confound than to

> inform. The subject I mean is electricity, which for some time past has become an object of such importance in physics that everyone is supposed to be acquainted with its effects. (Euler 1770–1774, Letter 138, Vol. 3, p. 277; Translation in Speiser (2008)) (A2)

Euler was primarily interested in the electric field, not in the charge (he was among those who rejected the idea that there were two types of electricity). For him electricity is due to the presence of one electric fluid, the aether which in normal circumstances fills the pores which travers all bodies in all directions. The electric qualities of a body depend on how easy or how difficult the pores are to open. In conductors (modern term) – metals and such – the aether can easily flow in and out; in this case, the pores are always open, so to speak. With other materials a certain strength is required to open the pores through friction: these are the insulators (modern term).

To magnetism instead Euler dedicated some papers and letters, see, for instance, Radelet de Grave and Speiser (2004) and Euler (1748a, b). Magnetism also is associated to a fluid. Originally – in the *Anleitung*, for instance – in Euler's opinion, the same aether was responsible for gravity, magnetism, electricity, and light. In the *Lettres*, in particular in Letter 176, instead he was of the opinion that the aether associated to magnetic forces was a special kind of subtle matter and not simply the subtlest part of a single all-pervading aether (Euler 1770–1774, Letter 176, Vol. 3, pp. 118–119). He seems never to have had any doubt that the light aether is responsible for the electric phenomena as well.

2.3 Matter and Its Properties

Euler dealt at length with bodies, matter, and related properties here and there in his scientific works. However, there are some papers in which he focused specifically on the subject. Among them: *Dissertatio de igne, in qua ejus natura et proprietates explicantur* written in 1737, *Gedancken von den Elementen der Körper* of 1746, *Recherches physiques sur la nature des moindres parties de la matiere* of 1746, *Réflexions sur l'espace et le tems* of 1748, *Recherches sur l'origines des force* of 1750, *Lettres à une princesse d'Allemagne sur divers sujets de physique & de philosophie* of 1760–1761, and *Anleitung zur Naturlehre* of 1750s. (Euler published anonymously *Gedancken von den Elementen der Körper*, an anti-Wolffian work. It was immediately recognized as bearing his signature however.)

According to Euler, bodies are characterized by the following general properties: extension, mobility, inertia, and impenetrability. Among them the fundamental is impenetrability which as such should be considered the very essential property of the bodies.

> Whatever is impenetrable belongs to the category of bodies, and therefore the essence of bodies is their impenetrability, on which therefore all the other properties must be founded (Euler 1862, Vol. 2, p. 472). (A3)

A body has extension in common with space and mobility with moving images projected on the wall, both of which however do not possess the property of impenetrability.

According to Euler, from impenetrability, extension and mobility follow. His argumentation on these points has more a rhetorical than demonstrative value but is equally interesting. From the very convincing thesis (a) no-extension → no-impenetrability, from the rule of classical logic, it follows (b) impenetrability → extension. More difficult is to argue (c) impenetrability → mobility; indeed a thing can be at rest though impenetrable; thus impenetrability is not necessary for actual motion; what can be said is that impenetrability is not in contrast with the possibility of motion, that is, mobility, but this makes weak the implication (c).

Inertia, called persistence (Standhaftigkeit) in the *Anleitung*, is also associated by Euler with impenetrability being linked to mobility "because when a thing is mobile, it should also have persistence, since otherwise any change would occur without sufficient reason" (Euler 1862, Vol. 2, p. 472), and mobility implies impenetrability. But the derivation (d) impenetrability → persistence has more problems than derivations discussed previously. Euler's strategy is to prove the implication (e) mobility → persistence that with the implication (c) would give (d). The derivation of the implication (e) implies the principle of inertia that Euler, like d'Alembert, based on the principle of sufficient reason, which has been the object of criticism by many scholars. Because implication (d) would derive from two weak implications (c) and (e), it would consequently be two times weak. For a different view on this point, see Gaukroger (1982, pp. 141–142).

According to (Gaukroger 1982), the idea that impenetrability constitutes the essence of body depends upon two Euler's claims: it is unique and necessary to a body, and it is irreducible, in the sense that conceiving a body as impenetrable is a primitive clear notion. Both Boscovich in the *Theoria philosophiae naturalis* of 1758 and Kant in the *Metaphysische Anfangsgründe der Naturwissenschaft* of 1786 thought impenetrability of bodies an obscure idea requiring elucidation in terms of a more basic notion that of repulsive force. For them, repulsive force was the physically primitive notion not requiring further elucidation, just as attractive force was physically primitive (Gaukroger 1982, p. 140). Considering that Euler was deriving force from impenetrability (see below), his is exactly the opposite path from that of Boscovich and Kant.

Bodies are portions of matter; thus Euler devoted a lot of attention to the properties of matter. The *Recherches physiques sur la nature des moindres parties de la matiere*, a relatively early work, began with the following question: "It is an important question in physics and metaphysics to establish whether or not the smallest part of matter are similar to each other" (Euler 1746c, p. 289). Euler tried to give a physical answer to this metaphysical question coming to the conclusion that all the smallest parts of bodies, referred to as the *smallest molecules* of matter, are made of the same stuff. In order to speak about the smallest molecules, it is necessary to distinguish between the properly said matter (groben Materie), *gross matter*, characterizing the inertia of bodies to which only the term molecules is referred to, from another type of matter, which is usually not recognized as such, called *subtle matter*, interposed among molecules. Notice that notwithstanding Euler used the term molecules, he said nothing about a corpuscular conception of matter, that is, the molecules may be not corpuscles.

Following these premises, repeated some years later in the *Anleitung*, Euler argued that there are only two kinds of matter, a subtle matter and a gross matter. The different apparent nature and density of bodies depend on a different combination of subtle matter and gross matter, with the subtle matter that fills the pores of the gross matter that may be more or less numerous and great. The molecules of gross matter have no pores, and even if they cannot be divided in act, being extended, they can be divided with the imagination. The division of matter remained a theme dear to Euler, who maintained, if not an ambiguity, at least a lack of explanation. For liquids, with fairly simple reasoning, as already shown in the previous section, he had "succeeded" in proving that there are no indivisible finite molecules; for solids Euler escaped the problem of the actual existence of molecules; what he said concerned the extension which is always indefinitely divisible.

The thesis that there are only two kinds of matter is carried out by Euler with both physical and metaphysical arguments. Assuming a metaphysical point of view, he invoked a principle of economics, which however is not so rigid because at least two kinds are allowed. While for the gross matter Euler arrived at a more or less convincing argument on the fact that it is only of one kind, for the subtle one, he hypothesized that there may be more than one, perhaps only two. For what the uniqueness of gross matter is concerned, after making considerations based on daily experience that lead to believe that there is a single type of (gross) matter and that the differences found among the various bodies depend on the nature and quantity of the pores in it present, Euler passed to the demonstration of this affirmation, on the basis of two laws of empirical nature. The first law concerns the fact that the force of gravity varies with the inverse of the square of the distance, as Newton has shown (Euler's words), and thus the weight of bodies decreases with the square of their distance from the center of the earth. The second empirical law concerns the fact that bodies of different weight fall with the same temporal law (in vacuum).

From the law of the inverse of square, Euler proved that the density and thus the pressure of the aether toward the center of the earth which causes gravity (see below) must decrease with inverse proportion of the distance. Thus, if x is the distance from the center of the earth, the pressure of the aether should vary as $h - A/x$, being A a constant of proportionality and h the pressure of the aether when at rest, as it is for $x = \infty$. From this expression of the pressure, it is easy for Euler to prove that the weight of a body is proportional to the volume of the gross matter it contains. Then, from the independence of the temporal law of fall for bodies of different weight, and from the law of mechanics (force and mass are proportional), it easy to prove that weight and mass are proportional. Which implies that the mass is proportional to volume, and because mass for Euler is the same as quantity of gross matter, it means that the quantity of gross matter of body is proportional to its volume, and thus the density of gross matter is constant, and thus the gross matter is of one kind only (Euler 1862, pp. 542–545).

A first draft of the hypothesis of the existence of a subtle matter or aether can be found in the *Dissertatio de igne, in qua ejus natura et proprietates explicantur* that Euler wrote in 1737 for the award of 1738 proposed by the Académie des sciences of Paris, which was assigned to him (Euler 1752a). To explain the phenomenon of

combustion, Euler claimed that the flame arises from the sudden explosion of molecules of "materiae subtilis igneae compressae" and to illustrate his conjecture used a corpuscular model: "Let's imagine a great quantity of glass spheres, full of air strongly compressed, and this mass of spheres is the material we want. Suppose that only a sufficient force intervenes to break a single sphere; and it is clear that both the impetus of the air and the projection of the fragments of glass will produce a similar effect in the nearby spheres, and then from these in all the others, until all are broken, emitting with immense roar the air that they enclosed" (Euler 1752c, p. 10).

Euler went on to argue that the properties of fire, due to a specific igneous matter, are not reducible to the ordinary laws of mechanics, like the principle of inertia or the proportionality of action and reaction. The heat given off by the fire and the rapid spread of the flame in all directions violate these principles and must be explained in another way. It is necessary to resort to a further postulate: the existence of an aether, a substance distinct from the igneous particles. The flame does not instantly disperse in the air due to the resistance of this aether, much more elastic and rarefied of the igneous matter, which surrounds and holds the flame in an unstable equilibrium. The continuous shocks that are created at the limit between the aether and flame give place to vibrations that generate light and transmit it in a straight line, like it occurs for the waves in the air (Euler 1752c, p. 19). The postulate of the ether was certainly not new in the eighteenth century. Many variants of it were formulated that referred above all to the conjectures that Newton had advanced, albeit in a temporary problematic form. For a discussion of the various hypotheses discussed in the period 1740–1750 by physicists, see Cantor and Hodge (1981).

The properties of subtle matter had been discussed more in depth in the *Recherches physiques sur la nature des moindres parties de la matiere* and in the *Gedancken von den Elementen der Körper*, to be taken again in the *Anleitung*. In the second part of the former of the two papers, Euler first denied the possibility of the existence of vacuum with metaphysical considerations, scarcely convincing indeed while he did not mention a physical more convincing (for us) motivation, namely, that the presence of vacuum would not justify the oscillatory theory of light proposed in his *Nova theoria lucis*, where propagation is conceived, in analogy to that of sound, as elastic waves propagating in the medium. With regard to the nature of the subtle matter, he limited to assert that it is very different from the gross matter; it is not gross matter made of very tiny corpuscles separated by vacuum but rather a continuous substance or, with a technical modern word, a continuum.

> There will be thus at least two main kinds of matter; one [the gross matter] which gives the fabric of sensible bodies, whose the particles have all an unchangeable degree of density, which is even greater than the apparent density of gold; the other [the subtle matter] kind of matter will be that of which the subtle fluid which cause the gravity is composed, and we call the aether. (The density does not vary in time, that is, gross matter is incompressible (Euler 1862, Vol. 2, p. 510).) (Euler 1746c, p. 300) (A4)

In the *Anleitung*, Euler spook at length about his continuous *aether* and did not feel embarrassed to introduce a concept which was alien to the dominating mechanistic

philosophy where the aether had usually a corpuscular nature. Euler's aether fills the whole space, leaving no emptiness. Air consists essentially of aether with small corpuscles of gross matter. While the gross matter is incompressible, the aether is compressible:

> Gross matter is therefore not capable of any change other than in the appearance of its shape, which, if appropriate forces are available, can be changed in arbitrary ways.
>
> [...] It does not appear to be true that subtle matter also has always and everywhere the same density, such that it could through no force be driven into a smaller space. Instead an important difference between gross and subtle matter seems to be that the latter can be compressed. (Euler 1862, Vol. 2, pp. 511–512; Translation adapted from Hirsch E.) (A5)

The aether although has the property to expand or shrink and behaves like an elastic medium and has a certain density that is proper to it. However, in no case it is possible to reduce a portion of aether to a point, that is, to effectively annihilate it (Euler 1862, Vol. 2, p. 513). Euler clearly stated that the compressibility of subtle matter does not imply the violation of its property of impenetrability.

Euler did not propose a convincing, at least for a modern, explanation of the force/pressure caused by the elasticity of aether which is not deducible from any of the typical properties of matter, extension, inertia, impenetrability, and mobility and therefore should be treated as a primitive (essential?) concept. Forces on gross matter are explained in Euler's mechanics by means of impenetrability and inertia. For instance, suppose an elastic body in motion that impacts with a rigid surface, it receives a force and rebounds because of the impenetrability of the surface and the resistance to change its motion from the inertia of the ball. The pressure of the aether against a rigid surface cannot be explained in the same way because the inertia of the aether is assumed to be negligible: "because experience shows that the celestial bodies do not suffer effects with their impact with the aether that fills the universe" (Euler 1862, Vol. 2, p. 542). Certainly there is an analogy with gases; but in this case, one (Euler himself) can resort to a mechanistic explanation; this was what Daniel Bernoulli did in his *Hydrodynamica* of 1738: the pressure of a gas is determined by the impact of the particles on the walls of the vessel that contains it (Bernoulli 1738, pp. 200–203). But for Euler the aether is not formed by particles.

Euler also doubted that there is on kind only of subtle matter: "Whether there are several kinds of this subtle matter, some of which are denser than others, we shall not be discussing here, but if indeed there are several kinds, we shall refer to them collectively as subtle matter. As long as the explanation of what occurs in nature does not require several such kinds, it would be bold and against the rules of a sound science of nature if, merely following our imagination we were to increase the number of kinds of subtle matter" (Euler 1862, p. 509).

According to him, the aether that is found in the universe is compressed far beyond its natural state and consequently exerts a great elastic force on the bodies formed by the gross matter (Euler 1862, Vol. 2, p. 517), able to explain the resistance of the materials to rupture, their elasticity, and the force of gravity.

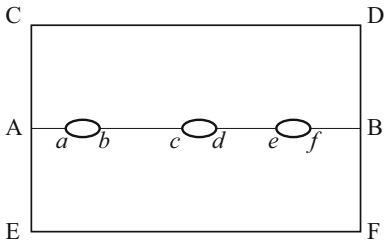

Fig. 1 Strength of bodies (Euler 1862, Vol. 2, Table XX, Fig. 235)

The resistance of solid bodies is associated with the hydrostatic pressure that the subtle compressed matter exerts on the various particles of ordinary gross matter, an explanation similar to that suggested by Galileo with the use of horror vacui. When two smooth grains of gross matter come into contact with each other, the elastic force of the aether makes them adhere strongly, and the breaking strength is maximum. If, on the other hand, the contact between the grains is not complete, then the breaking strength will be the minor the minor the contact surface.

To show this more clearly, let the two bodies of Fig. 1, ABCD and ABEF, be joined at the surface AB such that between them the cavities *ab*, *cd*, and *ef* are filled with the aether. The body ABCD will then be forced against the other body by the aether that presses on the planes CD and EF; on the other hand, it will be pushed back by the aether in the cavities *ab*, *cd*, and *ef*. Therefore the force with which the body ABCD is pressed against the other body ABEF is the result of the two constraining forces.

The lake of resistance in fluid is explained by the fact that here gross matter is so suffused by the aether that the particles have nowhere immediate contact. To see how this could happen, imagine that every particle of gross matter is surrounded by subtle matter, and the particles consequently never approach each other so closely that there would not remain some subtle matter between them. If every particle were at rest, such a mixing would be hard to understand; but if the subtle matter is in motion so that it continuously flows between the gross particles, then in this way immediate contact can be impeded (Euler 1862, Vol. 2, p. 535).

The elasticity is explained by admitting that inside bodies there are cavities (pores) filled with subtle matter that do not communicate with the outside. When a body is deformed, either compressed into a smaller space or expanded into a larger one, then there will be change in the size of its pores, some being expanded, but others being compressed.

> To explain this more clearly let us assume in the first place that a body is compressed into a smaller space. Since gross matter itself is incompressible, this cannot happen other than by making the pores smaller. In that case the apparent density of the body must increase, because the whole matter of which the body consists, or at least the gross matter, since the subtle matter can be neglected here, must have been brought into a smaller space. Let a^3 be that part of the body that is filled with gross matter, and e^3 the remaining part that only contains subtle matter, the sum of all pores taken together, then $a^3 + e^3$ is the size of the body, a is its mass and $a^3/(a^3 + e^3)$ is its density. But a^3 cannot be changed, therefore when the body is brought into a smaller space only e^3 is diminished. [. . .] If after the change in shape

> of a body the closed pores are neither larger nor smaller, then the body retains this changed shape. But if the closed pores become wider or narrower, then a force will develop in the body tending to restore the previous shape. (Euler 1862, Vol. 2, pp. 537–538; Translation by Hirsch E.) (A6)

The elasticity of commonly experienced bodies is thus explained by means of the elasticity of the aether, which is clearly a vicious circle. Thus what Euler actually explained was not the elasticity itself but rather why bodies made by an incompressible matter exhibit elasticity and why the elasticity differs from body to body. The difference in elasticity lies in the diversity of the dimensions and arrangement of the pores.

The account above referred about elasticity explains the behavior of the various elastic bodies, for example, the loss of elasticity as a result of heating. Indeed, the subtle matter contained in the pores is set into motion by heat, opening up access to previously closed pores; at the end the matter has less and larger pores than before. Therefore even though before heating there were large forces, these can vanish after heating.

The weight of the bodies, that is, gravity, is explained by admitting that the density, and therefore also the pressure of the aether surrounding the earth, increases by increasing the distance from its center. Euler is very precise in his explanation. Gravity should be associated to the gradient of pressure in the aether around the earth that determines the movement of the ethereal fluid downward with the consequent downward drag of the gross matter, determining the heaviness of the bodies (Euler 1862, Vol. 2, p. 542).

The section devoted to the heaviness of bodies ends with the consideration that even if one does not know why the pressure decreases in proximity to the planets, to stay with this doubt is always better than not knowing anything as when one says that the heaviness is due to attraction.

> Although we have to stop here and hardly can hope ever to find the cause of the diminution of the elastic force of the aether, it is easier to resign to this than to merely maintain that all bodies are by their nature endowed with a force to attract each other. For since one can not even form an understandable concept of this attraction, one can by way of contrast at least understand how it is possible that the elastic force of a liquid matter is reduced, and one also understands that this can occur in a way that is in accordance with the laws of Nature. (Euler 1862, Vol. 2, p. 547; Translation by Hirsch E.) (A7)

2.4 The Origin of Forces

Force in the eighteenth century was the fundamental magnitude of mechanics and was introduced in various ways, each with its own problems. In his youthful treatise of 1736, the *Mechanica sive de motu analytice exposita*, Euler introduced the concept of force in a classical and rather generic way. The force [potentia] is "an action on a free body that either leads to the motion of the body at rest, or changes the motion of that body" (Euler 1736, p. 78). If in this treatise Euler payed no care to

explain the nature of force, he did in subsequent works. It is worth noting that Euler had two Latin terms to indicate force: *potentia* and *vis*. To potentia he gave the technical meaning of cause of the variation of the motion of a body; to vis a generic meaning, either technical or common, for example, he can speak of *vis gravitatis* as an example of technical use, as well as of vis inertiae and the vis of impenetrability, as an example of common use.

Many years later, when he wrote the *Theoria motus corporum solidorum seu rigidorum*, with a much clearer understanding of mechanics, Euler proposed the definition:

> Definition 12. What induces to change the absolute state of bodies is named a *force* [vis]; it should be due to external causes, since the body will remain in its own state due to internal causes (Euler 1765c, p. 44). (A8)

Is there any change in the status of force (in the ontology); from a being has it became a name and instead of a potentia a vis? The question mark is justified also because in the *Anleitung*, preceding of some years the *Theoria*, Euler in a succinct proof of the laws of motion had written that force is measured by the effect it produces: Here he wrote: "A force twice as big must in the same time produce twice as big an effect, because just in view of that do we consider it twice as big" (Euler 1862, Vol. 2, p. 476). A similar position is also reiterated a few pages after Definition 12 in the *Theoria*, as will be commented in a subsequent section. In any case the above definition hides some ambiguities, always present in the scholars of the eighteenth century when they deal with force.

In the following in the attempt to decipher the complex argumentations on the concept of force, I will assume that *force* is for Euler a primitive concept, which in particular is reduced to the anthropomorphic idea of pressure. What Euler tried to explain is not what is force or pressure but what is its origin. The fact then that the Definition 12 defines force as the name given to the external cause of the change of motion does not regard ontology but simply serves to delimit the broader concept that force has in the natural philosophy of the period, somehow a hypostatization of any cause, also internal.

In the *Recherches sur l'origine des forces* of 1750, he had paused on the role of impenetrability only to explain forces. Euler observed that despite the inertia or the general property of bodies by virtue of which each body tends to preserve its state, we see that bodies that fall under our observation continually change their state. So these bodies are subject to forces that must necessarily be external (Euler 1752d, p. 423).

To illustrate the role of impenetrability to generate forces Euler considered two bodies A and B. A is at rest, while B is moving toward A. After the impact, in order to avoid its own penetration, A acts to change the state of B, and in turn B acts on A. In other words, A applies a force to B (due the impenetrability of A, which is an external cause) and B to A. Euler concluded that these forces see their source in the impenetrability only (Euler 1752d, p. 427). That is, the forces due to impenetrability are passive forces (modern term); they are not determined neither for their quantity

nor for their direction; they only are "obliged" to act when the impenetrability of a body is threatened; otherwise they do not produce any effect.

It is true that a greater action would prevent penetration as well, but it is more natural to assume a minimal value; that is forces have at all times value and direction strictly necessary to prevent penetration, so that if a minimum force is sufficient for the purpose only it acts (Euler 1752d, pp. 430–431). In this criterion of "least action," Euler took inspiration from Maupertuis, and in it, one can find a justification of the principle of least action. To Maupertuis he made explicit reference in the letter 78 of the *Lettres* (Euler 1775, Vol. 1, p. 304).

Euler argued that the forces that two bodies exchange are equal and opposite to each other. For Euler this equality of forces, which is commonly known as the principle of action and reaction, is a necessary consequence of the penetration. So, for him, it is a rational and not an empirical law.

> This equality of forces, hence the great principle of equality between action and reaction, is a necessary consequence of the nature of penetration. For, if it would be possible for the A body to penetrate the body B, body A would be equally as much penetrated by the body B; therefore, since the damage that these bodies that penetrate, is equal, these two bodies must also employ equal forces to resist penetration. So, as much as the body B is solicited by the body A, that will be solicited equally by this, both deploying exactly as much force as necessary to prevent penetration. But these two bodies acting one on the other by any force, will be in the same state as if they were compressed together by the same force (Euler 1752d, p. 434). (A9)

Euler was also able to analyze the evolution of the force due to impenetrability in the case of impact. Differently from many scholars of the period and in agreement with Johann Bernoulli (and Leibniz), he assumed that impact is not an instantaneous process: "The instantaneous impact would not be in accordance with the always respected law of nature, for which nothing can occur instantaneously, and as for a leap. According to this law a so great change, as sometimes is that occurring in the impact of bodies cannot occur without corresponding to a some interval of time" (Euler 1746a, p. 36).

In the hypothesis that the impacting bodies are linear elastic Euler furnished an explicit expression of the force of impact during the process of compression following the impact. If P is such a force, it is given by the expression $P = F/kz$, where F is the force necessary to get a penetration k, while z is the current value of the penetration. For reasons of space and also because it is not relevant for the present text, I do not repeat the mathematical steps involved in the proof. I limit myself to say that the approach and the result are essentially the same Euler had obtained in his youthful work *De communicatione motus in collisione corporum* of 1731 (Euler 1738). The difference is that now Euler had a clear concept of mass, whereas in 1731 he had not. But the equations are the same, demonstrating how mathematics may be more powerful than physics.

In subsequent works Euler associated force not only with impenetrability but with inertia also. In fact if there were no inertia, the state of bodies could be

changed, and in principle it could be argued that as impenetrability causes a change in state, it also determines forces. But it would only be a meaningless word game. Imagine, for example, stopping a moving ball by opposing it a hand; if inertia would have no role in the explication of force, one could be free to assume the ball without inertia. In this case the ball would be rejected or stopped, but the hand would not notice anything; which is contrary to what happen in the real world. To obtain an effect, it is necessary that the ball is equipped with the ability to resist changes of motion, that is, that it has not zero mass (inertia). In the *Theoria* Euler limited himself to say that forces originate from impact of bodies because of their impenetrability. He wondered if all the forces have this origin. Without excluding the existence of other forces, he was content to say that a very important class of forces has this origin.

Here's how Euler describes the role of inertia: "The cause of those forces by which the state of a body is changed may be agreed to lie not in inertia alone but in inertia coupled with impenetrability. Indeed, seeing that only bodies can be said to be impenetrable, and since bodies are necessarily endowed with inertia, impenetrability as such involves inertia, so that impenetrability alone is rightly considered the source of all forces by which the state of bodies is changed. It will therefore be proper to consider this property more exactly as being the origin of all forces" (Euler 1765c, p. 46). He thus can still pretend that only impenetrability counts because inertia is given when impenetrability is given.

The account of the force of impact between the two bodies A and B considered above may be completed as follows: when B comes into contact with A, it experiences a force which we would normally term A's force of resistance to change of state. Note that the force is not in any sense in A: what is in A is its inertia, which is not a force (according to Euler's definition) because it only maintains A's state. But this internal principle is experienced by B as a force. There is, therefore, an external force acting on B which is not internal to A. Nor does it act at a distance because it is a prior condition of there actually being a force that A and B be impenetrable and that they be in contact (Gaukroger 1982, p. 147).

Euler underlined in several occasions that the forces of impact are external to the bodies and that inertia is not a force in the sense that it is not responsible for the change in the motion of a body; it has only the role of preventing it. In his work of 1746 *Gedancken von den Elementen der Körper* (Euler 1746b), Euler criticized Leibniz's, or rather Wolf's, philosophy of forces and monads. Euler's main criticism concerned Wolf's thesis that the monads, which are the ultimate components of reality, are endowed with an internal force that intends to continually change their state. Euler believed that there was indeed an internal strength, which however tended to maintain the state and not to change it and concluded: "One must therefore stipulate that two particular well differentiated classes of things exist in the world, to one of which belong the corporeal things, whose essence consists in the force [ability] steadily to maintain their state. The other however comprises the souls and ghosts, which are endowed with a force to change their state" (Euler 1746b, p. 15).

2.5 Concepts of Time and Space

Euler discussed the concepts of space in his more technical works such as the *Mechanica sive de motu analytice exposita* and *Theoria motus corporum solidorum seu rigidorum* and in some more philosophical ones such as the *Lettres* and *Anleitung*. But the text in which it did so in a systematic way is *Réflexions sur l'espace et le tems* of 1748 (Euler 1750). Euler's discussion is interesting because it shows how a mathematical-oriented mind addressed some issues of philosophy of nature and metaphysics; he had perhaps less philosophical culture than a professor of philosophy, but he knew much more directly the topic he is dealing with. Euler's paper did not escape to Immanuel Kant (1724–1804) who read it 15 years after its publication. Kant observed that the mathematical considerations of motion and space furnished many data to guide the metaphysical speculation in the track of the truth, by thus considering mathematics and physics as a tool to avoid the void speculations of the philosophers of his time (Cassirer 1953, p. 351).

Euler defended his thesis of absolute space against the theses of "metaphysicians" who believe that only the concept of relative space makes sense. The metaphysicians in question are naturally the followers of Leibniz and Wolf, not explicitly named however. That he referred to them is evident when he stated "I strongly doubt [...] that the equality of the spaces should be judged by the number of monads that fill it" (Euler 1750, p. 331).

He addressed his thesis of absolute space with metaphysical and physical reasons. The metaphysical reason consists in affirming that a fertile concept in physics cannot be empty: "One should instead assert that both the absolute space and the absolute time, such as mathematicians look at, are real things which submit outside our imagination, because it would be absurd to sustain that pure imaginary objects could be assumed as foundation of the real principles of mechanics" (Euler 1750, p. 326). The physical reason is that only by conceiving absolute space can one explain the inertia of bodies.

Euler discussed inertia by referring it to a body at rest. He affirmed that to explain the difficulty to put it in motion from rest, its place (position) must be thought of as absolute – although in fact it is not possible to individuate any absolute system he added. Euler argued with a simple example that inertia cannot depend on the presence of nearby bodies to which refer motion considering a body that floats on still water, remaining at rest in its turn. If the water begins to flow, an observer, rigidly linked with it, sees the body move without any force being applied to it. Or if he sees the body remaining at rest with respect to the water, a careful examination shows him that this is due to the effect of water dragging. So Euler can conclude: "I strongly doubt that metaphysicians dare to sustain that bodies maintain their position with respect to other bodies thanks to their inertia, because it could be easy to show the falsehood of this explanation because of the consideration I discussed on bodies close to their neighbor" (Euler 1750, p. 328).

Euler then dealt with the case in which the position of a body is referred to fixed stars. Being them at rest – a possibility that is not certain for Euler (Euler 1765c, p. 38))

– the absolute space of the mathematicians would coincide with that of the metaphysicians. But, he wondered, how the fixed stars so far can determine inertia? This is impossible according to Euler.

This thesis, rejected by Euler, is endorsed by some modern scientists, who also refer to the reflections on the subject by the epistemologist Ernst Mach.

> As Ernst Mach has pointed out, it cannot be a coincidence that the fixed stars appear indeed fixed relative to inertial frames, and hence that it is reasonable to consider inertia as a force exerted on local objects by the totality of the objects in the entire universe. Thus, Newton's law may best be interpreted as a consequence of the basic axiom that the sum of the forces, including the inertial force, acting on a particle should be zero and of the constitutive law of inertia, which states that this inertial force should be given by $-ma$, where a is the acceleration relative to an inertial frame (Noll 2004, p. 9).

In essence Euler concluded that the preservation of the state (motion or rest) of bodies is explained only by conceiving place according to the criterion of mathematicians in an absolute space and not in relation to other bodies. And nobody can say that the principle of inertia is based only on something that exists in our head.

The reality of space is confirmed by the principle of preservation of uniform motion in a certain direction. If space was a relative concept, what sense would it have to speak of direction? It must be a direction of an absolute space that can be conceived in a natural way by abstraction.

Euler ended his considerations on space by reiterating the metaphysical argument that one cannot say that a principle accepted as true in physics by nearly all scholars (the principle of inertia), is founded on a thing that exists in our imagination only (the absolute space), and from this it must be concluded that the mathematical idea of absolute space cannot be in any way imaginary, but that there is something of real in the world which corresponds to this idea (Euler 1750, p. 329).

According to Ernst Cassirer, the *Réflexions sur l'espace et le tems* set up in fact not only a program for the construction of mechanics but a general program for the epistemology of the natural sciences. It sought to define the concept of truth of mathematical physics and contrasted it with the concept of truth of the metaphysicians. The considerations of Euler rested entirely on the foundations on which Newton had erected the classical system of mechanics. His concepts of absolute space (and absolute time, see below) were revealed not only as the necessary fundamental concepts of mathematical-physical knowledge of nature but as true physical realities. To deny these realities on philosophical grounds means to deprive the fundamental laws of dynamics – above all the law of inertia – of any real physical significance. In such an alternative, the outcome cannot be questioned: the philosopher must withdraw his suspicions concerning the "possibility" of an absolute space and an absolute time as soon as the reality of both can be shown to be an immediate consequence of the validity of the fundamental laws of motion (Cassirer 1953, p. 351).

Once established the reality of space, Euler went on to examine time. Beginning with the observation that the ideas of space and time always go together (Euler 1750, p. 331). Arguing on the reality of time is however more complicated. Euler

distinguished between the idea of time and time itself. He had no objection to the idea that time is conceived as a succession of changes. But this idea is not sufficient to assert that two time intervals are the same, as one has to say in mechanics. Thus, according to Euler, time cannot be reduced to the idea of succession of changes; there must be something else: absolute time. Euler concluded by saying that he realized that his considerations could only be taken on by philosophers who are willing to give some sense of reality to time and motion, while they will not make the slightest impression to those who consider everything as relative (Euler 1750, p. 333).

3 Mechanics and Mathematics

Euler was lucky enough to be born in a period when there was to build all the mechanics and all the Calculus starting from the foundations of the seventeenth century. His precursors and heirs have been sought. He has often been seen as the successor of Newton and Leibniz. It must be said that his role in mechanics has been overshadowed by the historians of mechanics such as Mach, Dugas, Montucla, and Dühring, very careful to the fundamentals, who see him more as a mathematician than a mechanician. After all, more than 60% of his work deals with pure mathematics, and even those whose object is mechanics and astronomy contain many sections that can be classified as mathematics. Today Euler's role, even for what concerns the fundamentals of mechanics, is re-evaluated. Some see him as the founder of modern classical mechanics as well as the one who threw the germs of the theory of relativity and quantum mechanics (Suisky 2009).

Regarding the legacy left by Euler, we must distinguish between the actual one, that is, the influence that he had on his contemporaries and the influence he could have had if all of his writings had been published and understood and also the influence it could have on modern mathematicians and physicists if they were still studied. On this last point, I limit myself to note that many of Euler's scientific writings could still well understood by a modern reader and that it is still possible to identify promising lines of research now abandoned.

In any case the genesis of Euler's thought, although interesting, is not a priority of this book. The reference to predecessors and contemporaries in mechanics is considered only on specific points, the main objective being to expose and explain his ideas. In this chapter I will focus almost exclusively on the fundamentals of Euler's mechanics, largely neglecting his elaborations in the areas of rigid body dynamics, theoretical astronomy, theory of elasticity, and fluid dynamics, even though they represent the greatest contribution of Euler to mechanics.

In my analysis, I will undergo a critical examination of the current points of view, due in large part to Truesdell's studies who edited (Vols. 12 and 13) or co-edited six volumes of the collected works of Euler and wrote appreciated articles and essays on him. He was Euler's greatest advertising agent, making him an eighteenth-century hero, a genius like Newton and perhaps superior to him. The current point of view can be summarized as follows:

1. Euler translated Newton's mechanics into Leibnizian language.
2. He introduced the use of vector calculus in mechanics.
3. He defined precisely the mechanics of the mass point, starting from the uncertain Newtonian mechanics.
4. He defined precisely the mechanics of the rigid body.
5. He made fundamental contributions to the systems of deformable bodies.
6. He founded modern hydrodynamics.
7. He introduced the concept of observer.

I will not stop to question these theses, limiting myself to say that it is one of the many myths of historiography that sees the evolution of science due to the work of isolated geniuses. It is hard to imagine that one man, not even one with exceptional memory and great workmanship and intelligence like Euler, could have done so much on his own. However, I believe that it is true that Euler was able to gather and summarize the ideas of his time, and for this reason, when one does not care about the genesis of the various ideas but wants to take stock of a certain era, the study of his research must be considered as essential.

The reconstruction of the basis of Euler's mechanics is carried out here by studying his published works – articles and books – and some letters. The main text which has been considered is *Theoria motus corporum solidorum seu rigidorum* (hereinafter *Theoria*), written in 1760 and published in 1765 (Euler 1765c). That is, I will start from a text in which the foundations of mechanics have already been laid. Of course, I will also refer to the *Mechanica sive de motu analytice exposita* (herein after *Mechanica*), published in 1736, and to articles and books that show both his researches and conceptions of natural philosophy, among which the most important is the *Anleitung*.

Euler had his own clear idea of how to develop a mechanical theory able to solve the problems that were then still waiting for a solution. Already in his early treatise, the *Mechanica*, he presented the work program that engaged him throughout his life: developing all the mechanics starting from the laws of motion of the mass point, a concept that he was among the first to specify. The mass point is the model with which the finite or infinitesimal bodies are studied when there is no interest in the extended objects. The mass of the whole body is thus imagined concentrated in one point, and the laws of kinematics and dynamics are applied to it. Here is Euler's program as reported in the general scholium of Chap. 1 of the *Mechanica*:

1. In the first place, very small bodies which can be considered as points are referred to.
2. Then the approach follows for these bodies of finite magnitudes which are rigid and are not allowed to change their shape.
3. In the third case, flexible bodies will be considered.
4. Fourthly, those which allow extension and contraction.
5. Fifthly the motion of bodies, constrained by others.
6. In the sixth case, the motion of fluids is in the agenda (Euler 1736, p. 37).

Never was Euler explicit about his metaphysical conceptions about mechanics. In particular, although in practice he treated mechanics as a purely rational discipline,

widely described with the language of Calculus, nowhere made his position explicit and never equated the status of mechanics with that of mathematics. Probably this silence was not due to an oversight but to some form of uncertainty. The only explicit statement he made about the role of mathematics in mechanics was his declaration of the preference given to the analytic treatment over the geometric one. For Euler only the former allows a systematic approach to all problems, while the latter involves the search for new routes for every problem. But this is of course true not only for mechanics but for mathematics in general, and it was for this reason that in the eighteenth century in every field of mathematics and physics, geometry was replaced by algebra and calculus, bringing the discipline of geometry to a state of decadence, from which it will recover only in the nineteenth century. Here is what Euler wrote about this point in the preface of the *Mechanica*:

> Thus, I always have the same trouble, when I might chance to glance through Newton's *Principia* or Hermann's *Phoronomia*, that comes about in using these [synthetic methods], that whenever the solutions of problems seem to be sufficiently well understood by me, that yet by making only a small change, I might not be able to solve the new problem using this method. Thus I have endeavored a long time now, to use the old synthetic method to elicit the same propositions that are more readily handled by my own analytical method, and so by working with this latter method I have gained a perceptible increase in my understanding. Then in like manner also, everything regarding the writings about this science that I have pursued, is scattered everywhere, whereas I have set out my own method in a plain and well-ordered manner, and with everything arranged in a suitable order. Being engaged in this business, not only have I fallen upon many questions not to be found in previous tracts, to which I have been happy to provide solutions, but also I have increased our knowledge of the science by providing it with many unusual methods, by which it must be admitted that *both mechanics and analysis are evidently augmented more than just a little*. (Euler 1736, Preface; Translation by Bruce I.) (A10)

The last sentence of the passage quoted above, in which Euler declared that the developments of mechanics and mathematics are closely linked, is worthy of note; mathematics allows to solve problems of mechanics; mechanics suggests cues to mathematics to treat unresolved problems.

3.1 Theoria Motus Corporum Solidorum Seu Rigidorum: The Motion of Mass Points

The first part of the *Theoria*, the *Introductio* (103 pages over a total of 527, preface excluded) reports a summary of the main results on the dynamics of the mass point, largely taking up from *Mechanica*, with many clarifications and updatings.

What a modern reader notices first, in reading the *Theoria*, though to a less extent to what happens for the *Mechanica*, is the verbosity of the exposition that in many cases instead of helping confuses and makes it difficult a reading because it does not allow to distinguish what is strictly necessary from what is superfluous. The sense of frustration is increased by the fact that in what is presented as a formal and generally axiomatic exposition, there is little or no distinction between theorems and principles.

Principles are almost never declared; the main exception concerns the principle of inertia.

Here is what Euler wrote about this point in the *Lettres*, a text following the *Theoria*, albeit slightly:

> This principle [of inertia] is commonly expressed in the two following proposition: A body once at rest will remain eternally at rest, unless it be put in motion by some external or foreign cause: Secondly, A body once in motion will preserve it eternally, in the same direction, and with the same velocity; or will proceed with an uniform motion, in a straight line, unless it is disturbed by some external, or foreign cause. In these two propositions consists the foundation of the whole science of motion, called mechanics. (Euler 1775, Vol. 1, p. 309; Translation in Euler (1802)) (A11)

While in the *Mechanica* the principle of inertia is not explicitly referred to as such, in the *Theoria* it is widely introduced with two propositions, qualified as axioms (see below). At no point is it referred to as a principle what a modern would treat as such, that is, the metaphysical principle of sufficient reason that plays a fundamental role in Euler's proofs.

The way of introducing and using principles becomes less mysterious if one reflects that the eighteenth-century mathematicians understood the term principle differently from us. They referred to a principle as a proposition placed at the foundation of a theory, requiring nothing else. Then the principle can be either first, that is, primitive, evident in itself or true empirically, or it can be a second principle if it can be demonstrated by first principles. Among the principles of mechanics, there are, for example, the principle of minimum action and that of the conservation of living forces. In Euler's time the logical status of these principles was not exactly defined; it was thought that they could be proved by first principles (and Euler will in part do so), but they still were not. Here is what Euler wrote about principles:

> XVlll. Although the principles in question are new, as they are not yet known or spread by the authors who have treated of Mechanics, it is understood, however, that the foundation of these principles cannot be new, but that is absolutely necessary that these principles should be deduced from first principles, or rather axioms, over which the doctrine of motion is established (Euler 1752a, p. 194). (A12)

The term *axiom* is used by Euler in the *Introductio* only three times to extend the validity of the properties from relative to absolute motion and to introduce the concept of inertia, with the classical meaning of a self-evident proposition. The term *theorem* is used eight times; there are then 15 definitions and 19 propositions qualified as problems. These propositions could generally be formulated as theorems because they provide the solution of the problems also. Euler's operation, perhaps similar to that of Euclid, serves to make the discussion less abstract.

The *Theoria* opens with the definitions of rest and motion:

> Definition I. Just as a body at rest remains perpetually in the same place, so a body in motion continues to change its position. Clearly a body that is observed to adhere always to the same place is said to be at rest: but that body which advances by gliding from place to place in time is said to be moving (Euler 1765c, p. 1). (A13)

The primitive concepts necessary to understand this definition, those of space and time, are introduced soon after, at a discursive level into two Explications and one Scholium. Space is introduced as an absolute entity "Now we can only conceive a notion about this space itself by abstraction, by considering all the bodies to be removed, and what is left we decide to call space" (Euler 1765c, p. 1), "a concept which was argued at length by philosophers (and uselessly)."

But the idea of absolute space, admitted Euler, cannot be used in practice neither to define the position of a body nor its motion. They must be referred to nearby bodies which must be able to maintain invariable in time positions relative to one another in order to fulfill the purpose. To determine the location of a point P, it is necessary to know its distance from at least four non-coplanar points A, B, C, and D (Euler 1765c, p. 2).

After introducing the reference system or using a modern term the observer, Euler went on to define the notions of relative motion and rest. A body is at rest with respect to A, B, C, D if its distances from them do not vary, otherwise it is in motion (Defs. 2, 3) (Euler 1765c, pp. 3–5). Note that Euler did not use the term relative, but "with respect to."

In a few definitions Euler introduced the concepts of path (Def. 4) and uniform and difform motions (Def. 5) and velocity (Def. 5), limited to uniform motion. Some comments are dedicated to the definition of velocity as the relationship between two heterogeneous quantities. The difficulty, inherent in the geometric concept of proportion and magnitude that requires comparison between uniform magnitudes, is solved by introducing units of measurement for space and time; in this way it is possible to define (the numerical value of) the velocity as the ratio between the numerical values that represent the measurements of space and time. Def. 7 concerns the direction of motion in the rectilinear and curvilinear cases, assumed as that straight line in which the motion is occurring or, if it is along a curve, as the tangent to the curve.

After these definitions Problem 1 follows, which deals with the use of the differential calculus to evaluate the space traveled by a point moving on a straight line with a velocity v assigned as function of time. Euler assumed that for a small dt (the element of time), the passed space ds, an elementary space indeed, is traversed with constant v velocity defined by $v = ds/dt$, in which v and s are explicitly thought of as generic functions of time, without particular restrictions on their regularity. (This is referred to as Proposition 3 in the *Mechanica*. "As indeed in geometry the elements of curved lines are considered to be the elements not-uniform motion is resolved into an infinite number of uniform motions. This is not the case, but it can be ignored without error. In either case the truth of the proposition is therefore apparent" (Euler 1736, p. 12; Translation by Bruce I.).)

The idea of considering constant any magnitude (in the present case the velocity) on condition of referring to a very small spatial or temporal intervals is what gives calculus a great heuristic power. If the velocity of the body v is given at individual instants, then the distances s passed in time t can be obtained with the help of the relation $ds = vdt$, the integral of which gives $s = \int vdt$. Similarly if the speed v corresponding to a distance s is known, then the time t, in which the distance s is passed, is given by the differential equation $dt = ds/v$, which gives $t = \int ds/v$.

More than one historian concedes that this approach to motion contains elements of novelty. Meanwhile, velocity is defined as a derivative (modern term, actually for Euler it was a ratio of differentials) of a function $s(t)$ which is considered as a generic mathematical function and therefore an abstract concept not necessarily connected to a geometric curve. Then time is treated in the same way as any other physical quantity, and it does not have a particular role as it happens, for example, in Newton, with his idea of fluxions (Suisky 2009, p. 132).

I do not pronounce on this judgment about Euler's originality. Certainly a similar treatment was not possible before the introduction of Calculus; furthermore it was established that Euler contributed a lot to the generalization of the concept of function. If one compares the way of treating velocity in the *Theoria* with that of the *Mechanica*, written 20 years earlier, he notices greater ease due to greater confidence both with the Calculus and the concept of function. It should be kept in mind that Euler's text also had a didactic function and the maturation of the concepts referred to was not only his but mainly of the contemporary readers who did not need to be reassured about the validity of the procedure.

Problem 2 considers the motion of a mass point on a plane curve. It is reduced to the study of two monodimensional motions projecting the velocity into two directions not necessarily orthogonal, even if, added Euler, it would be better if they were such, for reasons of simplicity of calculations. For the motion in space (Problem 3), the projection is on to three axes. It should be noted that this is only a kinematic problem where the problem of the legitimacy of decomposition does not arise.

Studying motion with respect to orthogonal coordinate axes instead of intrinsic or natural coordinates is considered a fundamental turning point in Euler's mechanics, a choice that appears first in his work *Recherches sur le mouvement des corps célestes en général* of 1747 (Euler 1749). The use of intrinsic coordinates, the standard approach at the turn of the eighteenth century, had two drawbacks. On the one hand, it required skill to find the right frame of reference. On the other hand, the approach was too difficult for bodies moving into a three-dimensional space. To be carried out consistently, it needed concepts of differential geometry such as curvature, torsion, and so on, fully developed only in the nineteenth century. The use of Cartesian coordinates does not present these problems. Although the equations may be complicated, they can be written in a standardized way. Even in this case, however, it must be said that Euler was not the first to project the equations of motion on two or three axes. According to Lagrange the first was Colin Maclaurin (1698–1746) in his *A treatise on fluxions* of 1742 (Lagrange 1811, p. 243).

> If the curve FM (Fig. 319) be described by powers directed in any manner whatsoever, and the force at any point M, resulting from the composition of these powers, act in the direction MK, and be measured by MK; let MK be resolved into the force MO in the direction of the ordinates MP ($=y$), and the force OK parallel to the base AP ($=x$); then, the time being supposed to flow uniformly, or the velocity at M being represented by the fluxion of the curve FM, the force MO will be measured by $\ddot{y}$ and the force OK by $\ddot{x}$ (Maclaurin 1801, Vol. 1, p. 298).

Johann Bernoulli also had done it according to (Maltese 2003, p. 210; Truesdell 1960, pp. 184–236, 1968, p. 112). But only with Euler, the use became systematic; indeed it became the only one.

The use of decomposing the motion into two or three directions can be seen as a step toward modern vector algebra. A same magnitude, a geometric vector, can give rise to different pairs (or triads if in space) of components as the coordinate system varies. The choice of the coordinate system can be arbitrary. To the decomposition of the motion in several directions, Euler gave the name *resolution*. The motion is said to be resolved, provided that the small interval traversed in the element of time is considered as the diagonal of a parallelogram or parallelepiped (Euler 1765c, Def. 8, p. 21). Euler also considered other types of coordinates and therefore of decomposition. In Problems 5 and 6, the polar coordinates are introduced in the plane and in the space, respectively.

In Chap. 1 of the *Introductio*, Euler carried out only kinematic considerations. In the following chapters, he went on to discuss the causes of motion. They are classified internal and external:

1. Internal causes. Responsible for the reason either for rest or motion of a body, with the exclusion of all external causes. They are able to contribute anything to change the state of motion or rest.

2. External causes. Responsible of the change of the state of motion and rest of a body.

To explain the nature and characteristics of internal causes, Euler devoted the entire Chap. 2. To achieve his purpose, he is forced to introduce the then controversial concept of absolute motion. In essence Euler said that, if there is the absolute space, of anybody one can say if it is at rest or in motion with respect to the absolute space. To these types of situation, he referred to as absolute motion or rest. This obvious fact can be expressed through an axiom:

> Axiom 1. Every body, even without being relative to other bodies, either remains at rest or moves, that is, it is either at absolute rest or in absolute motion (Euler 1765c, p. 30). (A14)

Two more axioms concern absolute motion; they express the principle of inertia, a term which Euler has not yet introduced.

> Axiom 2. A body, which is absolutely at rest, if subjected to no external actions, will persist indefinitely in the state of rest.
>
> Axiom 3. A body, which is absolutely in motion, if subjected to no external actions, continues to move uniformly along the same direction (Euler 1765c, pp. 32, 33). (A15)

These axioms, which Euler called the principles of internal motion, are justified in a simple way, basing on the principle of sufficient reason. For the state of rest, Euler argued, for instance, that because all the external causes of motion have been withdrawn, no reason is present that a body should begin to move in one direction rather than in any other: "This truth depends on the principle of sufficient reason" (Euler 1765c, p. 32).

A somewhat more sophisticated reasoning concerns the permanence in the state of uniform motion. No change in the direction can indeed occur, since there is no reason it should be deflected from that, in one rather than in all the other directions; "clearly it surely maintains the same direction, for the principle of sufficient reason." About speed [the modulus of velocity] it can be said that "unless it always remains the same, either it increases or decreases, of which neither absurdity can be said; for if it is either being increased or decreased, it must happen to follow a certain law; but what this law may be cannot be conceived in any way, since nothing surely will be agreed upon" (Euler 1765c, p. 34). The reader is asked to reflect on the validity of these demonstrations.

After the introduction of the three axioms, the first theorem (Theorem 1), which asserts that the axioms valid for absolute motion also apply to relative motion, provided that it refers to a body (to an observer) that is at (absolute) rest or in uniform rectilinear motion (Euler 1765c, p. 37), appears very simple in reality.

In Definition 11 the internal cause of motion is given a name, *inertia* (the persistence of the *Anleitung*):

> That quality of bodies, the reason for persisting in the same state present within a body itself, is called inertia, and also sometimes the force of inertia (Euler 1765c, p. 35, translation from Bruce I). (A16)

with the concept of state (absolute) introduced as follows: "While a body is either absolutely at rest or moving uniformly in a direction, it is said to persist in the same state" (Euler 1765c, p. 35).

Inertia indicates that property of bodies, whereby being at rest, means that they will continue to be at rest, therefore as if they oppose to motion; but since bodies set up in motion themselves equally oppose all to be changed, either on account of the speed or direction; this name seems a good choice. Sometime, said Euler, it is called *force of inertia*, because the body is resistant to change the state; but because often force is defined as the (external) cause which is changing the state of the body, force of inertia is not acceptable with this meaning – though Euler occasionally did. Whereby, as confusion should arise, it is better to omit the name force and refer to it by the simpler name of inertia (Euler 1765c, p. 36).

Chapter 3 is devoted to the external cause of motion; to it also is given the name *force*, with Definition 12. Though it has already been introduced before, I rewrite it for the sake of clarity:

> What induces to change the absolute state of bodies is named a *force* [vis]; it could be due to external causes, since the body will remain in its own state due to internal causes. (Euler 1765c, p. 44) (A17)

After the introduction of external and internal causes of motion, Euler could go on to demonstrate what is now known as the Newtonian equation of motion, for the one-dimensional case. In essence Euler considered as a necessary truth, that is, rational, the law that Newton considered contingent that is empirical. The demonstration takes place into two steps.

Theorem 2a. The small space [$d\omega$], through which a given body at rest is advanced in the assigned small interval of time dt by different forces, is proportional to the forces. (Euler 1765c, p. 55) (A18)

Theorem 3. If equal forces act on unequal bodies at rest, the effect [$d\omega$] produced in the same small time intervals [dt] is inversely proportional to the inertias of the bodies. (Euler 1765c, p. 56, translation from Bruce I) (A19)

The proof of Theorem 2a is very simple, based on the assumption of the additivity of the effect of different forces. Basically, said Euler, if a small body, a corpuscle, is pulled forward by a force equal to p in the short time interval dt through the small space equal to $d\omega$ and if another force equal to p is acting on the same body along the same direction, the body progresses through another equal small interval equal to $d\omega$. Thus this corpuscle acted on by a force equal to $2p$ in the same interval of time dt is pulled through the small distance equal to $2d\omega$. Similarly if n forces – or equivalently a force np – act on the corpuscle at rest for the same time interval dt, they move the body through the interval equal to $nd\omega$.

The demonstration is not convincing however. Euler assumed indeed that the effect of the sum of two forces (two causes) is the sum of their effects, that is, he is assuming a principle of superposition and this is not granted. (The principle of superposition presupposes for its validity that the two cause do not interact to give a cause different from their sum.) And even if this is conceded, the proof would be only a trivial theorem of arithmetics (at Euler's time) for which if two quantities increase of the same amount they are proportional. Moreover the demonstration follows a reasoning different from that carried out in the *Anleitung*. Here (*Theoria*), in the proof of Theorem 2a, force is considered as measured a priori; in the sense that it is independent of the formulation of dynamics, there (*Anleitung*) force was measured from effect, and the proof of the theorem becomes a simple truism.

Euler's writing is substantially contemporary to one of Daniel Bernoulli, the *Examen principiorum mechanicae, et demonstrationes geometricae de compositione et resolutione virium* of 1726 (Bernoulli 1728), in which the latter posed the problem of the logic status of the law that links acceleration to force, assuming force as defined a priori concluding that the law is empirical and not rational. Bernoulli said that the part of mechanics that deals with the balance of forces can be deduced from the principle of composition of forces, as Varignon has shown. If another principle is added to this principle, namely, that according to which the increases in velocity are proportional to the increments of time multiplied by the force, mechanics is completed, relative to the motion. Galileo used this principle. Bernoulli believed that the principle of composition of forces is a necessary truth, while that of Galileo is a contingent truth: "Nature could have made the increases in velocity in the bodies proportional to the increments of time multiplied by any function of the pressure, so that said t the time, p the pressure and v the velocity, it was not $dv = pdt$, but for example $dv = p^2dt$ or $dv = p^3dt$" (Bernoulli 1728, pp. 126–127).

The proof of Theorem 3 is analogous. Basically it is said that if one joins two bodies of equal mass under a given force, the effect is halved. With some details, following Euler's reasoning: Let consider a corpuscle having an inertia A, which at rest is moved by a force equal to p for the short interval of time dt through the small

space $d\omega$; if another corpuscle B equal to A is acted on by a force also equal to p along the same direction, it moves in the same dt by the same small space $d\omega$. If the two corpuscles are joined together into one resulting in a body with an inertia $2A$ (it is an implicit assumption by Euler), it acted by the force equal to $2p$, in the time equal dt moves still of the small space $d\omega$. Thus a force $2p$ on the body of inertia $2A$ produces the displacement $d\omega$. Similarly a force np applied to a body n A produces the same displacement $d\omega$. Thus for the Theorem 2a, the force p on a body n A produces a displacement $d\omega/n$.

Note that inertia is not equivalent to the Newtonian quantity of matter; it is rather a property of a body whose measurement is defined in an operational way as the constant of proportionality between force and displacement $d\omega$. Euler can thus introduce the concept of mass in the following way, with Definition 15:

> The *mass* or the *quantity of matter* of a body is the name given to the amount of the *inertia* which is present in that body, by which just as it tries to continue in its own state so it tries to resist all changes (Euler 1765c, p. 57). (A20)

where also the term quantity of matter is redefined by means of the concept of mass, inverting the usual approach where the mass is defined by the quantity of matter. The property of additivity is implicitly attributed to the mass as clear from the proof of Theorem 3. That is, if one joins two bodies with mass m_1 and m_2, he gets a body with mass $m_1 + m_2$.

The operational definition of mass in the eighteenth century used by Euler is not common; almost all mathematicians treat mass and inertia as proportional to the quantity of matter, taking for granted the meaning of quantity of matter (for instance, the number of atoms). The operational definition of mass will be resumed in the nineteenth century by Mach in his *Die Mechanik in ihrer Entwicklung historisch-kritisch dargestellt* written at the end of the nineteenth century (Mach 1919).

In the *Mechanica* Euler had given a different formulation of mass, and it is after a theorem – and not a definition – (Proposition 17) that the amount of inertia (vis inertia) is proportional to the amount of matter or mass (Euler 1736, p. 57). The amount of matter, however, was defined in a vague way, like the set of points (atoms?) that make up a body. Only that not all the points have the same mass. More precisely the points can be taken having the same mass when the same force exerts an equal effect on them (that is they have the same inertia). Thus the demonstration of the theorem on the equality between inertia and mass of the *Mechanica* is the result of a vicious circle of the type: the amount of matter is proportional to the amount of inertia, so the amount of inertia is proportional to the amount of matter.

At this point, by putting together Theorem 2a and Theorem 3 and using the definition of mass, Euler could enunciate Theorem 4, according to which:

> Theorem 4. If corpuscles at rest with masses in an unequal ratio, are acted on by some singular forces, the small intervals through which they are thrust forwards in the same short time intervals will be composed in the direct ratio of the forces and the inverse of the masses. (Euler 1765c, p. 59; Translation adapted from Bruce I.) (A21)

That is, for a force p and a mass A, it can be written $d\omega \propto p/A$.

In Problem 9, Euler started to replace the elementary displacement $d\omega$ measured from the rest with the variation dv of velocity. Coming to the relation (with his symbols):

$$dv = \frac{\lambda p dt}{A}$$

where λ is a proportionality constant necessary to move from a proportion to a formula, which is the natural way to work with algebra and Calculus. (Incidentally if A is the weight, as Euler always assumes, then λ coincides with the acceleration of gravity (modern meaning).) Euler basically said that the increment $d\omega$, for a given interval of time dt, is proportional to the element of velocity dv, and therefore for Theorem 4, the above relation follows.

A modern reader sees in the previous formula the second law of motion of Newtonian mechanics in the monodimensional case. To discuss whether Euler's was the first formulation of the equation of motion – it was not indeed – is not relevant here; certainly it was one of the first times the second law of motion was written in a very clear and unequivocal form. The only thing missing is the meaning of the constant λ; but this concerns only the choice of units of measurement and Euler made a choice later.

What leaves a little "surprised," especially if reading the *Theoria* immediately after the *Mechanica*, is the fact that dv is placed directly proportional to the time interval dt; Theorem 4 authorizes only to say that dv is proportional to p and inversely proportional to A. The proportionality between dv and dt had been treated as a theorem in the *Mechanica* (Proposition 15), attributing its discovery to Galileo, who actually saw it as a plausible hypothesis to be verified experimentally, or if not it, its consequence, that is, the law according to which spaces vary with the square of times.

> 135. Galileo was the first to use this theorem in the investigation of falling heavy bodies. Indeed he did not give a demonstration of it, however because of the strong agreement with phenomena, nobody doubted it anymore. (Euler 1736, p. 53) (A22)

Euler's demonstration is very simple but circular. This is how it works: consider n infinitesimal time intervals $d\tau$. The increase in velocity du is the same in each interval of time $d\tau$, assumed equal to each other, because by hypothesis the force, that is, the cause of motion is the same. So after n equal intervals $d\tau$, the velocity becomes $dv = ndu$, from which it follows that dv is proportional to $dt = nd\tau$ (Euler 1736, p. 51). The circularity is to admit the constancy of the increase in velocity over time, which is the same as saying that the increase in velocity is proportional to time.

The reasons for omitting the proof of proportionality of dv with dt in the *Theoria* are not clear, at least to me. It is possible that everything derives from Euler's, and others, studies on finite differences, in fashion in the early eighteenth century. These studies had shown that the variation of a function y of x, in a certain small interval dx,

is necessarily proportional to dx itself, that is, $\Delta y \sim \psi dx$, width ψ a proportionality constant, generally dependent on x. Euler assumed it natural to consider the variation of velocity dv that in a given interval of time, once force and mass are fixed, cannot but vary linearly with the infinitesimal interval of time dt, and therefore $dv = \psi dt$. The fact that ψ can only vary with p and A (and not also on the time t) depends on the physical nature of the problem that tells us that the variations of velocity in a certain interval are always the same (ψ= const.), or it varies as $\psi = \psi(p, A)$, but the case $\psi = \psi(t)$ is not discussed.

The motion of a body moving along a plane curve (Problem 13) following a force acting on the plane is treated by resolving the force into two (orthogonal) components and then studying two separate one-dimensional motions. It should be noted that unlike the case presented in the Problem 2, which was purely kinematic in nature, the idea of resolution or projection tends not to show the underlying physical principle, the parallelogram rule, for which the projections of forces are forces themselves that act independently of each other (without interaction). This is one of the cases in which the power of the mathematical instrument hides the physical nature of the problem. Indeed the use of Cartesian coordinates has deeper advantages than that of mere simplicity; the addition of vectors located at different points is so natural as to become customary at once, because it is reduced to the ordinary algebraic summation, giving for granted that this addiction has a physical meaning. Somehow Euler was aware of the problem and said that a force is traced back to three forces P, Q and R acting in the (orthogonal) directions x, y and z, with the "static resolution criterion" (Euler 1765c, p. 77).

The equations of motion eventually take the form (Euler 1765c, p. 85):

$$ddx = \frac{2gPdt^2}{A}; \quad ddy = \frac{2gQdt^2}{A}; \quad ddz = \frac{2gRdt^2}{A}$$

in which A is the mass, while the symbol g denotes the height through which a heavy body drops in the time of a second, in a specified region of the globe, in case mass and weight are assumed to have the same numerical value: "Let the mass of the corpuscle be equal to A, which clearly indicates as well the weight, if the corpuscle is situated in a region of the earth chosen to evaluate an absolute measure" (Euler 1765c, p. 77). (Note that g is one half the value of the acceleration of gravity G, this follows from the relation $s = 1/2Gt^2$: By assuming $t = 1$ it follows $g = 1/2G$.)

In these equations the constant λ has been replaced by $2g$. That is, a coefficient that had only the role to transform a proportion in an algebraic equation is given a mechanical meaning, the space traveled in one second. Still in his work of 1749, Euler had assumed $\lambda = 1/2$, which, in modern terms, corresponds to assume an acceleration of gravity $G = 1/2$ and thus $g = 1/4$. The choice had derived from the desire of giving a simple expression to the speed of fall from the height h, which is simply given by $v^2 = h$, instead of $v^2 = 2Gh$. No inconsistency is at play; it is just a different choice of units of measurement.

To note that the equations of motion Euler wrote are in accord with the rule of calculus of the eighteenth century, where the concept of differential was fundamental.

Using modern notation, Euler normally wrote the equation of motion as $mdv = fdt$, and not $ma = f$, where the symbols are the usual. However, he also used the acceleration a in a technical way, as the ratios dv/dt or dds/dt^2. This is what he wrote when integrating the equation of motion: [In dynamics] the effect should be measured by the acceleration or the change in the speed, that is impressed on the body in a given time: this is proportional to that force divided by the mass of the body. [...] dv is equal to the product of the acceleration and the element of distance travelled (Euler 1736, p. 84).

3.2 Measurement of Forces

The explanation of the origin of forces given in Euler's writings on natural philosophy, in the *Researches sur l'origine des forces* in particular, does not provide any criterion for their measurement. The force due to impenetrability is not measurable in itself as it exists only at the moment of impact. What, at least in principle, is measurable is its effect, which, for Euler according to the Newtonian approach, is expressed by the variation in velocity in an assigned small interval of time, in the case of the impact much less than the duration of the contact between the bodies that collide with each other.

In the writings specific on mechanics, such as the *Mechanica* and the *Theoria*, the problem is discussed a little more. In the first treatise, Euler showed no particular difficulty to introduce the measurement of forces. It could be obtained by the rules of statics, a discipline at the time considered well founded. These rules indeed allow to measure a force as function of a sample force, for instance, a weight. It is enough to evaluate how many unities of the sample force should be summed (the additivity of forces is granted, for instance, by the rule of parallelogram) to reach the equilibrium when they act in the opposite direction with respect to the force to be measured. This means that the measure of a force is a priori and independent of dynamics that is independent of the dynamical effect it produces.

Euler is more careful in the *Theoria*; here he distinguished between a static and a dynamic measure; of course when two forces measured with the two approaches give the same numerical value for Euler, the forces are equal under all the aspect, that is, there are not dynamic and static forces but only different ways to measure them; the dynamic way is used only when static measurements are not possible, as, for instance, it occurs for gravitational forces of astronomy.

Euler had established his equations of motion, Theorems 2a and 3, referring to the increment of the displacement of a body due a force starting from the rest, because only in this case he had an independent criterion to measure force, the static one. In the case of motion Euler said that nothing is known concerning the measurement of forces and the way to measure them is left to us: "Since in statics, from which we draw the measurement of forces, the bodies to which the measurements are applied, may be considered in a state of rest, and thus nothing is defined concerning the measurement of these forces when they act on the body in motion" (Euler 1765c, p. 53).

In dynamics the only way left for the measure of forces should be searched in the measure of the effects, that is, they can measured a posteriori only: "Therefore the

magnitude of these forces is determined not by the impenetrability, which clearly cannot be quantified, but from the change of the state which must be effected lest the body penetrate each other" (Euler 1765c, p. 50).

Euler, however, did not dwell at length on the problem of measuring forces and did not relate the dynamic and a posteriori measure of force, based on motions, with the static and a priori measure, based on the equilibrium. In such a way he avoided to make clear if the foundation of his mechanics is dynamic or static. Euler left comments on the dynamic measure of force only in some Explicationes of the *Theoria*, as he would not to compromise himself with strong declarations. Here he proposed the convention that if a force acting on a body in motion causes a displacement shift σ in the direction in which it acts, that force is assumed to be equal to the force that would cause the same displacement σ from the rest, evaluated, for instance, according to Theorem 2a (that is, if $\sigma = kp$ is the law derived from Theorem 2a and the shift of displacement measured for a body in motion is $\overline{\sigma}$, the force associated to this variation of motion is given by $\overline{p} = \overline{\sigma}/k$).

> 144. For the forces, then, by which bodies already in motion are acted upon, we set up this ground of measuring, so that we shall judge these equal to those which would have executed the same effect on the same bodies at rest in the same time. This ground, however, does not require proving, because it rests upon a definition and thus it was open to us to establish it. For if for any motion the small space $s\sigma$ should be equal to small space $S\sigma$, through which the same small body at rest is brought forward in that same little time by force p, we also call those forces equal. (Euler 1765c, p. 53; Translation in Pourciau (2016)) (A23)

Of course if it is admitted to measuring force through its effect, the Newtonian law of motion could be considered as a simple definition, and the concept of force could become superfluous. Only a weak ontological substratum would remain which allows to attribute some reality to force; but it is a link that can be broken without substantial changes in the formal development of mechanics. This link will be broken, shortly after the publication of the *Mechanica*, for example, by d'Alembert.

One could say that Euler preferred pragmatism to rigor. His alleged apodictic foundation of mechanics based on principles, self-evident for him, as those of impenetrability and inertia of bodies, works only if one remains at a superficial level, but above all it is not able to explain all the mechanics, for example, the link between statics and dynamics. Of course one could also criticize the evidence of the ideas of impenetrability and inertia or the lawfulness of the use of the principle of sufficient reason, but these criticisms should apply to the whole period in which Euler lived.

4 The Apparent Motion and the Observer

Although Euler believed in the existence of an absolute space, he nevertheless believed that motion, as a matter of fact, could only be studied in a relative space, defined by a certain conventional reference frame. It will then be the task of the physicist to establish what relationships exist between the relative space chosen to

study motion and the absolute space. This is, for instance, what Euler wrote in his *Mechanica*, and in other occasions:

> Because of the immense nature of space and of its unbounded nature [...] we are unable to form a fixed idea of this. Thus, in place of this immense space and of the boundaries of this, we are accustomed to defining a finite space and the limits within which bodies can move, from which we can indicate the states of motion and of rest of bodies. Thus, we are accustomed to say that a body that keeps the same situation with respect to its boundaries is at rest, and truly that which changes with respect to the same, to be in a state of motion. (Euler 1736, Vol. 1, p. 2; Translation by Bruce I.) (A24)

In the *Anleitung* Euler posed himself the problem to see what happens by changing the reference frame, in particular by considering two reference frames in motion with respect to each other, a problem which had ancient origins. Galileo founded his mechanics referring to thought experiments imagining to be in the cabin of a moving ship. Huygens also set out on a uniform motion to study the problem of collision. Euler is part of this tradition, also followed by some mathematicians at the beginning of the eighteenth century, but as usual, he specified and enlarged it. A fairly detailed analysis of his modus operandi can be found in (Maltese 2000; Bertoloni 1993).

Already in one of his works of 1739 in which he addressed the problem of the influence of the speed of light propagation in astronomical observations, Euler faced the purely kinematic problem to correct the observational data to take into account the fact that the observers (spectatores in Latin) based on the earth mobile with respect to the fixed stars (Euler 1739a).

In Chap. 10 of the *Anleitung*, Euler systematically introduced the concept of observer, to which he referred to with the German term Zuschauer, which is properly translated as spectator, basically a fixed or mobile coordinate frame (without clock). There are some important results that clarify what today is known as the Galilean principle of relativity. Thanks to the use of Cartesian coordinates and calculus, the mathematical passages that Euler had to face appears very simple to a modern.

The first proposition states:

> If the observer moves at constant speed along a straight line, and estimates directions correctly, then all bodies that are either at rest or are moving at constant speed in a straight line will appear to him to remain in the same state. (Euler 1862, Vol. 2, p. 497; Translation by Hirsch E.)

Notice that it is not specified very clearly the observer is considered to be moving with respect to the absolute space. The second proposition basically states that the equations of motion are the same for an absolute system and for a system that moves uniformly with respect to it:

> If the observer moves uniformly in a straight line, and if he judges directions correctly, that is according to parallel running lines, then the maintenance of the apparent movement requires the same forces as the true movement, however much the apparent movement may differ from the true movement. (Euler 1862, Vol. 2, p. 497; Translation by Hirsch E.) (A25)

In the two propositions, the statement asserting that the direction is judged correctly means in modern term that the observer is moving without rotation.

In the following I refer with some details Euler's proof. Let's assume three coordinate axes in the absolute space, OA, OB, and OC and call the components of the motion (velocities) along the axes u, v, w. The motion of the observer is defined by velocities α, β, γ that by assumption are constant. To the observer, the motion of the body as seen from the axis OA will appear the smaller, the faster his own motions. The apparent motion in the direction of the axes OA, OB, and OC will be $\underline{u} = u - \alpha, \underline{v} = v - \beta, \underline{w} = w - \gamma$, respectively. From the equations of motion that Euler had already developed, it follows that for the maintenance of the true (absolute) motion, one requires three forces, $MP = P,\ MQ = Q,\ MR = R$, so that:

$$P = \frac{Mdu}{ndt}; \quad Q = \frac{Mdv}{ndt}; \quad R = \frac{Mdw}{ndt}$$

where M is the mass and n a normalizing factor. Now replace u, v and w, by $\underline{u}, \underline{v}, \underline{w}$, in these equations. Since α, β and γ are constants, the differentials remain unchanged, so that it is apparent that for the maintenance of the apparent motion the same forces P, Q and R are required as for the true motion.

In a third proposition, perhaps the newest one, Euler considered an observer which moves in a translational way (without turning) unevenly. In this case, he concluded that fictitious forces must be considered alongside real forces.

> But if the observer does not move uniformly in a straight line, *but does estimate directions correctly* [emphasis added], then to maintain the apparent motion of all bodies, in addition to the forces that are actually acting on the bodies, further forces are required that will at every instant and in every body produce the change that takes place at the location of the observer, but acting in the opposite direction. (Euler 1862, Vol. 2, p. 498; Translation by Hirsch E.) (A26)

In this case also the proof is very simple. However arbitrarily the motion of the observer may change, with reference to the three assumed axes; it can always be represented by the three motions (velocities) α, β and γ by taking these quantities to be variable. Now if the true movement requires the forces:

$$P = \frac{Mdu}{ndt}; \quad Q = \frac{Mdv}{ndt}; \quad Q = \frac{Mdw}{ndt}$$

By replacing u, v, w by $u - \alpha$, $v - \beta$, $w - \gamma$, the maintenance of the apparent motion will require the following three forces:

$$\text{Kraft} \quad MP = \frac{Mdu}{ndt} - \frac{Md\alpha}{ndt} = P - \frac{Md\alpha}{ndt}$$
$$\text{Kraft} \quad MQ = \frac{Mdv}{ndt} - \frac{Md\beta}{ndt} = Q - \frac{Md\beta}{ndt}$$
$$\text{Kraft} \quad MR = \frac{Mdw}{ndt} - \frac{Md\gamma}{ndt} = R - \frac{Md\alpha}{ndt}$$

Therefore, apart from the forces P, Q, R that actually act on each body, three additional forces are needed that in each body produce the same change that occurs at the location of the observer, but in the opposite direction.

The above proposition of Euler finds its applications on several occasions. In the *Theoria*, for example, he finally applied it to astronomy, in order to eliminate the non-inertial motion of the observer's frame based on the earth (Euler 1765c, pp. 120–121). In his important work on water wheels, Euler studied the action of a jet of water coming out of a rotating pipe (Euler 1756). To determine this action, the observer is located in a frame rigidly linked with the pipe (Maltese 2000, p. 342; Bertoloni 1993, pp. 322–326). An approach that will be followed by the nineteenth-century engineers involved the study of turbines. In a more general study of 1755, Euler arrived to formulate relations that have analogies, a part from some mistakes in calculation, with the famous relations that Gaspard-Gustave de Coriolis (1792–1843) found almost a century later (Bertoloni 1993, p. 326; Maltese 2000, pp. 342–342), with reference to a problem similar to that faced by him, that is a rotating wheel.

5 Dynamics of Rigid Bodies

The problem of the motion of rigid bodies, particularly of their rotation, has been the subject of careful studies since the middle of the seventeenth century. It was then presented as the problem of the composite pendulum and its reduction to a simple pendulum. Descartes, Roberval, and Huygens had dealt with the problem (Capecchi 2014) and then the Bernoullis. In 1745 Daniel Bernoulli wrote to his friend Euler at the end of 1745 of the problem as a very difficult and almost impossible to solve for anyone (Truesdell 1968, p. 257).

Euler succeeded in the enterprise shortly after Bernoulli's letter with his famous paper *Decouverte d'un nouveau principe de mecanique* (Euler 1752b), presented at the Académie royale de science et belles lettres de Berlin in 1750. The locution "noveau principe" referred to in the title of the paper at a first reading appears to coincide with those that today go under the name of equations of motion of the mass point in a system of three coordinated axes, which Euler had already presented in another of his works, the *Recherches sur le mouvement des corps célestes en général* of 1749, without referring to it as a new principle. Historians have often questioned in which sense this principle was new. Generally, in the past, it was considered that the title adopted by Euler was improper; after all it was not Newton who had written the equations of motion? And in any case Euler himself had rewritten them a year before. More recently, however, a great originality has been sustained, thus passing from one extreme to another (Truesdell 1968; Maltese 2001).

There are some novelties with respect to the paper of 1749. The mass to which "Newton's equations" refer are not necessarily of isolated bodies; they may also be of infinitesimal bodies, that is, the elementary mass dM of the corpuscles which are – true or imaginary – part of an extended body, for the moment considered as rigid. And the forces acting on these corpuscles are not only the external forces acting on

the whole body but also the constraint reactions that come from the surrounding corpuscles to maintain the constraint of rigidity. So the novelty of Euler would be of method, in the sense that the motion of an extended body is studied using the same laws that apply to a mass point, thus reducing mechanics to a single principle, as Euler had always declared he wanted to do, and of merit because in these equations a broader concept of force is used.

The historians who praise Euler's role, however, are silent on the fact that d'Alembert in 1749, a year before Euler presented his work, wrote *Recherches sur la precession des equinoxes* that although starting from different principles of mechanics presented an approach that was equivalent to that of Euler from a mathematical point of view. It equally based on infinitesimal elements of the extended body, the earth, by calculating the necessary force to keep it in motion, as a product of the infinitesimal masses for their acceleration due to gravitation forces, according to relations derived from the study of the kinematics of rigid bodies and by imposing the equivalence of the (static) moments of these forces with those of the external forces. Among other things, with his principles, d'Alembert was not obliged to call for the constraint reactions, which somehow caused embarrassment to Euler (see below). However, regardless of whether Euler's work was original or not, it was certainly fundamental for the evolution of his thought and also of the mechanics of eighteenth century.

Here is as Euler presented his new principle: Let consider an infinitely small body, whose mass M (dM) is assumed to be contained in a single point. Suppose that that body of mass M has received an arbitrary motion along the direction x and that it is acted on by arbitrary forces P, we will have:

$$2Mddx = Pdt^2$$

with the symbols having the usual meaning. "And it is this formula alone, which contains all the principles of mechanics" (Euler 1752b, p. 195). A similar reasoning can be repeated for the direction y and z and forces Q, R arriving to the equations (Euler 1752b, p. 196):

$$2Mddx = Pdt^2; \quad 2Mddy = Rdt^2; \quad 2Mddx = Rdt^2$$

which are exactly the same as those reported in the paper of 1749.

> It is thus from this same great principle that it will be necessary to derive all the rules which we need in order to determine the motion of a solid body whose axis of rotation does not remain immobile. For this purpose, it will be necessary to consider not only all the elements of the body, but also their mutual connection, in virtue of which all the elements maintain among themselves the same order and the same distances. For the motion of the whole body is composed of the motions of all its elements, and the motion of each of these must follow the principle which I have just explained, given that each element participates in the forces [*f*] which act on the body, and, in addition, *is affected by certain forces [r] which prevent it from losing its connection with the others* [emphasis added]. But before we can determine the effect of the forces to which the elements are subjected, we must consider in general the motion to which such a body is susceptible. (Euler 1752b, p. 197; Translated by Langton SG.) (A27)

The motion of a rigid body subject to generic forces is decomposed into the motion of the center of gravity and the motion around it, that is, a rotation. For the first motion, Euler merely stated that it obeys the laws of motion valid for the mass point by considering the mass of the whole body concentrated in its center of gravity and subjected to a force equal to the resultant of all the forces acting on the body.

To study the rotating motion, Euler considered a frame fixed with the origin in the center of gravity of the body and three non-rotating axes AO (z), BO (y), and CO (x) and studied the motion, displacement, velocity, and acceleration, of a mass corpuscle dm, which occupies the position x, y, z, when the body rotates around an axis passing through O. Rotation is defined by the components λ, μ, and ν of the angular velocity vector with respect to the axes x, y, z.

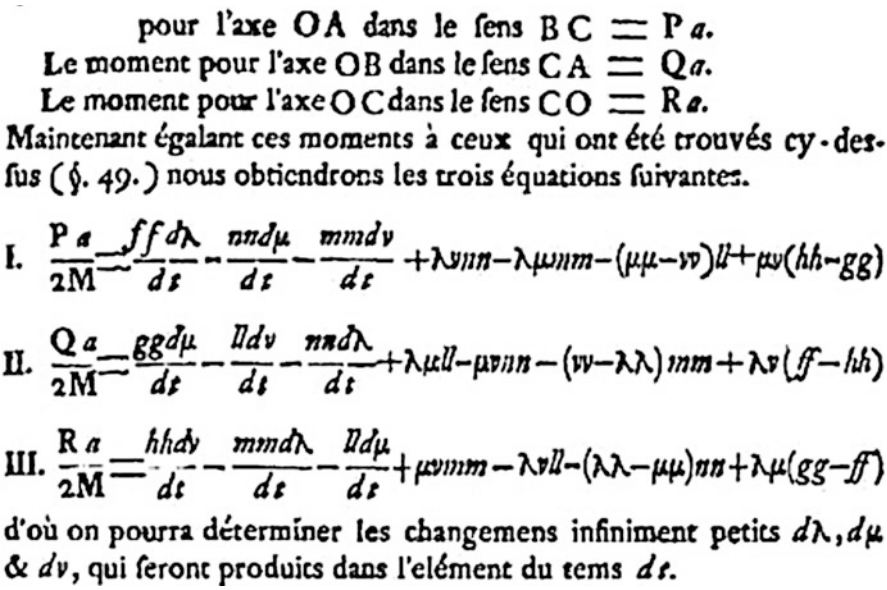
Once found the expression of ddx, ddy, ddz, starting by the kinematic relations of x, y, z and the angles of rotation, he equated the resultant moment of the masses multiplied by acceleration (ma) to the resultant moment of the forces ($f+r$) acting on the body with respect to the fixed axes. (In modern term, given the equation of motion $ma = f + r$, Euler made equal the moments of the two members of the equality.) In the analysis of the forces, Euler believed he could ignore the constraint forces (r). For which "it is to be remarked that the internal forces mutually cancel one another, so that the continuation of the motion requires only the external forces, to the extent that those forces do not mutually cancel" (Euler 1752b, p. 206). It is not clear here whether Euler refers to the principle of action and reaction or, more simply, to the shared axiom of mechanics that a body cannot modify its motion due to internal forces. Truesdell thinks that Euler drew his idea from Daniel Bernoulli (Truesdell 1968, pp. 252–256).

The result of Euler's calculations is shown in Fig. 2. In the Eqs. I, II, and III, M is the mass of the whole body; ff, gg, and hh are in the order the axial moments of inertia (Euler term) with respect to the axes z, y, x, while ll, mm, and nn are the mixed moments of inertia with the pairs of axes xy, xz, yz, respectively, and λ, μ, ν are the components of the vector of angular rotation according to the axes z, y, x. Pa, Qa, Ra are the (static) moments of the external forces with respect to the axes z, y, x.

Euler referred to the Eqs. I, II, and III as "three formulas which contain the new principles of Mechanics which we need in order to determine the motion of solid bodies." They are quite complex, especially because the moments of inertia are referred to fixed axes, thus: "it is necessary to calculate anew for each instant the values ll, mm, nn, ff, gg, hh, because they will vary as a result of the change in the position of the body with respect to the three [fixed] axes" (Euler 1736, p. 214).

Euler took up the subject of the rigid body motion in later works, the results of which are summarized in his *Theoria* of 1760 where there are no substantial new elements compared to what Euler had written in the previous 10 years. Besides writing the equations of motion of the rigid body, Euler also dealt with complex problems, including gyroscopic motions.

A superficial reading of this "applicative" part makes it clear the perspectives that calculus has opened to the mathematical investigation of motion. It also makes manifest the theoretical and practical difficulties that arise in the solution of the differential equations of motion which requires the development of new fields of mathematics.



pour l'axe OA dans le ſens BC = P a.
Le moment pour l'axe OB dans le ſens CA = Q a.
Le moment pour l'axe OC dans le ſens CO = R a.
Maintenant égalant ces moments à ceux qui ont été trouvés cy-deſſus (§. 49.) nous obtiendrons les trois équations ſuivantes.

$$\text{I.}\quad \frac{P\,a}{2M} = \frac{ff\,d\lambda}{dt} - \frac{nn\,d\mu}{dt} - \frac{mm\,d\nu}{dt} + \lambda\nu nn - \lambda\mu mm - (\mu\mu - \nu\nu)ll + \mu\nu(hh - gg)$$

$$\text{II.}\quad \frac{Q\,a}{2M} = \frac{gg\,d\mu}{dt} - \frac{ll\,d\nu}{dt} - \frac{nn\,d\lambda}{dt} + \lambda\mu ll - \mu\nu nn - (\nu\nu - \lambda\lambda)mm + \lambda\nu(ff - hh)$$

$$\text{III.}\quad \frac{R\,a}{2M} = \frac{hh\,d\nu}{dt} - \frac{mm\,d\lambda}{dt} - \frac{ll\,d\mu}{dt} + \mu\nu mm - \lambda\nu ll - (\lambda\lambda - \mu\mu)nn + \lambda\mu(gg - ff)$$

d'où on pourra déterminer les changemens infiniment petits $d\lambda$, $d\mu$ & $d\nu$, qui ſeront produits dans l'elément du tems dt.

Fig. 2 Motion of a rigid bodies about a movable axis (Euler 1752b, p. 213)

To confirm what was already clear to Euler since 1736, that mechanics and mathematics proceed together, because a part of mechanics has now become mathematics itself.

However, the way in which Euler reached the equations of motion is also interesting from a foundational point of view. He did so by making explicit what was implicit in his article of 1750. He started from the idea of *elementary (disturbing) forces*, that is, those forces that applied to each element of the body separately may produce the same change in their state as likewise actually found (Euler 1765c, p. 117). The elementary forces, if applied in the opposite direction to the body, reduce it to rest. This is, as shown in the next chapter, what goes under the name of d'Alembert principle (introduced in 1743). Euler did not mention d'Alembert, and with a little reason because he had already used this approach in his previous works, but without giving him the relief that he is giving it here. To distinguish the *elementary disturbing forces* from the "ordinary forces," he will refer to the latter as the *actual forces*. Euler referred to the principle of d'Alembert as a "well known circumstances which can be deduced from the principles of metaphysics, always fully effective according to reason. But this principle should be correctly understood; and indeed it is usually proposed generally in a vague manner, so that its conclusions cannot be reached without any risk" (Euler 1765c, pp. 119–120).

> Moreover here the actual forces acting bear the causes in turn, that we designate by the letter *V*; then the effect is twofold: on the one hand, by which the motion of the body is affected, in place of this the elementary forces are to be assumed immediately effecting a change in the motion, which forces likewise we denote by the letter *T*. Now the other effect consists in trying to change the structure of the body, in place of this the forces affecting the bonds must be taken, which we denote by the letter *S*. Therefore since from the cause *V* there is produced

> the effect equal to $T + S$, it must be considered that $V = T + S$, thus on collecting terms together, $S = V - T$, in short as we have found above. (Euler 1765c, pp. 119–120; Translation by Bruce I.) (A)

The equations of motion to translation and rotation of a rigid body are obtained by equating the resultant and (static) moment of the elementary and external forces, according to the rules of statics.

Euler devoted a particular care to constraint forces, that is, the forces, to which the constraints of body must resist, which can be obtained as the resultant of the forces actually disturbing the body and the elementary forces applied in the opposite direction. The actual forces with the elementary forces taken away must give the forces affecting the constraints. How a body resists to these forces depends on its structure and on the way the parts of the body are connected together, which refers to physics rather than to mechanics. However, Euler said we only assume bodies, of which we consider the motion, to be provided with a sufficient level of stiffness, so that no change in the shapes be apparent. Of course it is sufficiently plausible that the connection of the parts is not so strong to not give way a little bit, although this could escape our senses. If it is true, then clearly no body is able to be taken as rigid, unless those where in general there are no forces trying to disturb the bond, since even by the smallest forces a certain change in the shape is being produced. "Now whatever such rigid bodies, assumed here, are present in the world or not, this question does not touch on the present discussion, since in all disciplines it is not needed that the objects are in existence to be contemplated" (Euler 1765c, p. 120).

Studies carried out by Euler on the motion of a rigid body in the period 1750–1760 are very well summarized in (Maltese 2000, 2003). In 1751 Euler employed axes rigidly linked to the body (in the following *body axes*) and noticed the existence of axes of free rotation (Euler 1767). After János András Segner (1704–1777) had discovered in 1755 the existence of at least three of such axes named principal axes of inertia, Euler explored their properties in *Du mouvement de rotation des corps solides autour d'un axe variable* (Euler 1765b) and arrived in 1758 to the three equations of motion of a rigid body, which are named after him in the paper *Du mouvement de rotation des corps solides autour d'un axe variable* of 1758 (Euler 1765a) and which are much simpler that those reported in Fig. 2.

They are in the form (Euler 1765a, p. 165) (Note that the two papers of 1751 and 1758 have very similar title and sometimes are confused. This has occurred also in the Euler archive.):

$$P = Maa\frac{d \propto \cos}{2gdt} + M(cc - bb)\frac{\propto\propto \cos\beta\cos\gamma}{2g}$$

$$Q = Mbb\frac{d \propto \cos\beta}{2gdt} + M(aa - cc)\frac{\propto\propto \cos\gamma\cos\alpha}{2g}$$

$$R = Mcc\frac{d \propto \cos\gamma}{2gdt} + M(bb - aa)\frac{\propto\propto \cos\alpha\cos\beta}{2g}$$

where $\propto$ is the modulus of the angular velocity; α, β, γ are the angles the axis of rotation makes with the body axes a, b, c, the principal axes of inertia passing from

the center of gravity; *aa*, *bb*, *cc* are the moment of inertia with respect to the principal axes; *P*, *Q*, *R* are the component of the (static) moment of the external forces with respect to the body axes; *M* is the total mass of the body (actually the weight); and *g* is one half of the acceleration of gravity. These equations are much simpler than those referred to in Fig. 2.

After 1760, Euler came back to the study of the motion of rigid bodies. In a work of 1775, *Nova methodus motum corporum rigidorum determinandi* (Euler 1776), Euler now 70 years old and with impaired sight rewrote the equations of motion of the rigid body in the form shown in Fig. 3, where *x*, *y*, *z* are the coordinates of the mass point *dM* with respect to a fixed coordinate system; *P*, *Q*, *R* and *S*, *T*, *U* are, respectively, the components with respect to *x*, *y*, *z* of the resultant of forces and (static) moments with respect to the center of gravity of external forces; *i* is the acceleration of gravity. The integral must be extended to the body of which the motion is studied.

Truesdell (Truesdell 1968) gives much importance to the Eqs. I–VI of Fig. 3. In his opinion:

1. It is the first time that the equations of motion appear altogether, rotation and translation.
2. They have general validity, that is, they apply to all types of bodies, even those that are not rigid.
3. The equations apply not only to the whole body but also to each of its finite or infinitesimal portions.

Eodem modo pro axe I B obtinebimus hanc aequationem:

$$\int x\,d\,M\left(\frac{d\,d\,z}{d\,t^2}\right)-\int z\,d\,M\left(\frac{d\,d\,x}{d\,t^2}\right)=i\,T.$$

Tertia vero aequatio erit pro axe I C

$$\int y\,d\,M\left(\frac{d\,d\,x}{d\,t^2}\right)-\int z\,d\,M\left(\frac{d\,d\,y}{d\,t^2}\right)=i\,U.$$

§. 29. Hac igitur ratione ſex nacti ſumus aequationes, quas hic coniunctim conſpectui exponamus

I. $\int d\,M\left(\frac{d\,d\,x}{d\,t^2}\right)=i\,P$ IV. $\int z\,d\,M\left(\frac{d\,d\,y}{d\,t^2}\right)-\int y\,d\,M\left(\frac{d\,d\,z}{d\,t^2}\right)=i\,S$

II. $\int d\,M\left(\frac{d\,d\,y}{d\,t^2}\right)=i\,Q$ V. $\int x\,d\,M\left(\frac{d\,d\,z}{d\,t^2}\right)-\int z\,d\,M\left(\frac{d\,d\,x}{d\,t^2}\right)=i\,T$

III. $\int d\,M\left(\frac{d\,d\,z}{d\,t^2}\right)=i\,R$ VI. $\int y\,d\,M\left(\frac{d\,d\,x}{d\,t^2}\right)-\int z\,d\,M\left(\frac{d\,d\,y}{d\,t^2}\right)=i\,U.$

In

Fig. 3 Equations of motion of a rigid body (Euler 1776, p. 224)

4. The Equations of moments IV, V, and VI are treated as if they were independent of the Eqs. I, I, and III.

Truesdell's theses deserve respect, considering the long study he has dedicated to Euler, but they are ideologized, in the sense that Truesdell having made Euler his champion tends to attribute him the authorship of the principles used in modern continuum mechanics.

I will comment on Truesdell's thesis point by point.

1. It is true that the equations of equilibrium to translation and those to rotation appear together for the first time in Euler's texts and therefore also in the history of mechanics. But this is not particularly significant. Euler had in fact already written since 1750 equations similar to those presented in the work of 1775. Any compiler by reading Euler's texts would effortlessly summarize his mechanics with the equations of Fig. 3.
2. It is true that the equations of Fig. 3 have general validity. They represent the equilibrium equations of mechanics regardless of the nature of the bodies to which they refer, hence independently of what today goes under the name of constitutive relationship, that is, the fact that the body be rigid, or perfectly flexible as a chain or elastic (the *elastica*, for instance), or fluid body. For example, in Euler's text of 1775, it can be assumed that Euler had consciously defined the constraint of rigidity starting from coordinate transformation expressed by the relations:

$$x = f + FX + F'Y + F''Z$$

$$y = g + GX + G'Y + G''Z$$

$$x = h + HX + H'Y + H''Z$$

where x, y, z are the coordinates of the element dm, in the fixed coordinate system; X, Y, Z are the coordinates of the same element with respect to the body axes, whose axes which, for instance, coincide with the barycentric principal axes of inertia; f, g, h are the coordinates of the center of gravity, in the fixed coordinate system. $F, F', F'', G, G', G'', H, H', H''$ are the cosines directors of the body axes with respect to the fixed coordinate system. Substituting these relations in the equations of Fig. 3, one obtains the equations of motion of the rigid body. But it is not at all certain that Euler was aware of the generality of his results. At least this does not result from the reading of the work of 1775, in which explicit reference is made to the rigid body only.
3. In the work of 1775, the integrals are extended to the whole body only.
4. Reading the work, it seems that Euler proceeded in the same way as in 1750; that is, he started from the forces on the mass element dm and then evaluated the resultant for translation and rotation. However, compared to 1750 or even 1760, he forgot the constraint reactions and their role. It is obviously difficult that this

was a forgetfulness. It remains to be seen whether Euler ignored constraint reactions for simplicity of treatment, considering that he intended essentially to present equations of the motion of the rigid body in a different form from what has been done in previous works. Or instead he chooses of adopting two independent principles instead of just one. This however would completely transform the axiomatic of Euler and would void his ideal of unification and rationalization. A discipline based on a single principle demonstrated a priori, and therefore purely rational, would pass to a physical-mathematical discipline based on two principles, of which no explanation can be given, which confer hypothetical nature to the theory, leaving its verification to the agreement with the experimental results, perhaps too modern for Euler.

According to Truesdell his thesis would also be confirmed by the approach followed by Euler in the study of deformable continua. An in-depth study of the study in this direction is not of interest for the following writing; moreover, most likely it would not lead to a conclusive result.

6 Quotations

A1 Eine flüssige Materie muss zu allererst diese Eigenschaft haben, dass ihre Theilchen nicht aneinander befestigt sind, so dass ein jegliches Teilchen ohne einigen Widerstand von den übrigen abgesondert und in Bewegung gesetzt werden kann

A2 La matière, sur laquelle je voudrois à présent entretenir V.A. me fait presque peur. La variété en est surprenante, & le dénombrement des faits sert plutôt a nous éblouir qu'à nous éclairer. C'est de l'Electricité dont je parle, & qui depuis quelque tems en devenüe un article si important dans la Physique, qu'il n'est presque plus permis à personne d'en ignorer les effets.

A3 Alles was undurchdringlich ist, gehört in das Geschlecht der Körper, und daher besteht das Wesen der Körper in der Undurchdringlichkeit, in welcher folglich alle, übrigen Eigenschaften ihren Grund haben müssen.

A4 II y aura donc deux especes de matiere, l'une qui fournit l'étoffe à tous les corps sensibles et dont toutes les particules ont la même densité, qui est très considerable et qui surpasse meme de plusieurs fois celle de l'or; l'autre espece de matiere sera celle dont ce fluide subtil qui cause la gravite est compose, et que nous nommons l'ether.

A5 Die grobe Materie ist also an sick selbst keiner anderen Veränderung fähig als in Ansehung ihrer Figur, welche, wenn hinlängliche Kräfte vorhanden, auf alle mögliche Arten verändert werden kann.

[. . .] Dass die subtile Materie auch allezeit und allenthalben eine, beständige Dichtigkeit haben sollte, dergestalt, dass dieselbe durch keine Kräfte in einen kleineren Raum getrieben werden kannte, scheint der Wahrheit nicht gemäss zu sein. Vielmehr mochte auch hierin ein

Hauptunterschied zwischen der groben und subtilen Materie bestehen, dass sick diese zusammendrücken liesse.

A6 Um dieses deutlicher darzuthun, so wollen wir erstlich setzen, ein Körper werde in einen kleinern Raum zusammengepresst. Weil sich nun die grobe Materie fur sich nicht zusammenpressen lasst, so kann dieses nicht anders geschehen, als wenn die Poren kleiner gemacht werden. In diesem Falle muss demnach die scheinbare Dichtigkeit des Körpers wachsen, weil die ganze Materie, woraus der Körper besteht, oder zum wenigsten die grobe, da die subtile in Ansehung derselben für nichts zu achten, in einen kleinern Raum gebracht worden. Es sei a^3 der Theil des vom Körper eingenommenen Raumes, welcher mit grober Materie angefüllt ist, e^3 aber der ülbrige Theil, so nur subtile Materie in sich enthalt, oder die Summe von allen Poren zusammen genommen, so wird $a^3 + e^3$ die Grosse des Körpers, as seine Masse und $a^3/(a^3 + e^3)$ seine Dichtigkeit aüsdrucken. Nun aber kann a^3 nicht verändert werden, daher, wenn der Körper in einen kleinern Raum gebracht wird, so wird nur e^3 verringert oder [...] Wenn nach geschehener Veränderung der Figur eines Körpers die verschlossenen Poren weder grosser noch kleiner werden, so behalt der Körper diese veränderte Figur. Wenn aber die verschlossenen Poren weiter oder enger werden, so wird sick in dem Körper eine Kraft äussern, sick wieder in seine vorige Figurherzustellen.

A7 Ungeachtet wir aber hier stehn bleiben müssen und kaum hoffen können, jemals die wahre Ursache dieser Verminderung der elastischen Kraft des Aethers zu ergründen, so kann man sich doch damit leichter begnügen; als wenn man blosserdings vorgiebt, alle Körper seien von Natur mit einer Kraft begabt, einander anzuziehen. Denn da man sich von diesem Anziehn nicht einmal einen verständlichen Begriff mach en kann, so kann man im Gegentheil zum wenigsten überhaupt einsehn, wie es möglich sei, dass die elastische Kraft einer flüssigen Materie vermindert werde, und man begreift auch, dass dieses auf eine den Gesetzen der Natur gemässe Art geschehen könne.

A8 Qiucquid statum corporum absolutum mutare valet, id vis vocatur; quae ergo, cum corpus ob causas internas in statu suo esset permansurum, pro causa externa est habenda.

A9 XXXL. Cette égalité des forces, d'ou depend le grand principe de l'égalité entre l'action & reaction, est une suite necessaire de la nature de la penetration. Car, s'il étoit possible que le corps A pénétrat le corps B, le corps A seroit précisément autant péenétre par le corps B; donc, puisque le danger que ces corps se pénètrent, est égal de part & d'autre, il faut aussi que ces deux corps employent des forces égales pour resister a la penetration. Ainsi, autant que le corps B est sollicité par le corps A, précisément autant sera celui-cy sollicité par celui-là, l'un & l'autre déployant exactement autant de force qu'il faut pour prevenir Ia penetration. Or ces deux corps agissant l'un sur l'autre par une force quelconque, se trouveront dans le même état que s'ils étoient comprimes ensemble par Ia même force.

A10 Idem omnino mihi,cum Neutoni Principia et Hermann Phoronomiam perlustrare coepissem, usu venit, ut, quamvis plurium problematum

solutiones satis percepisse mihi viderere, tamen parum tantum discrepantia problemata resolvere non potuerim. Illo igitur iam tempore, quantum potui, conatus sum ex synthetica illa methodo elicere easdemque propositiones ad meam utilitatem analytice pertractare, quo negotio insigne cognitionis meae augmentum percepi. Simili deinde modo alia quoque passim dispersa ad hanc scientiam spectantia scripta sum persecutus, quae omnia ad meum usum methodo plana et aequabili exposui atque in ordinem idoneum digessi. Hoc in negotio occupatus non solum in plurimas antea nondum tractatas incidi quaestiones, quas feliciter solutas dedi:sed etiam complures peculiares methodos sum adeptus, quibus tam mechanica quam ipsa analysis non parum augmenti accepisse videantur.

A11 Or on énonce communément ce principe par deux propositions, dont l'une porte, qu'un corps étant une fois en repos demeure éternellement en repos, à moins qu'il ne soit mis en mouvement par quelque cause externe ou étrangere. L'autre proposition porte, qu'un corps étant une fois en mouvement, conservera toujours éternellement ce mouvement avec la même direction & la même vitesse, ou bien sera porté d'un mouvement uniforme suivant une ligne droite, à moins qu'il ne soit troublé par quelque cause externe ou étrangere.

A12 Quoique les principe dont il s'agit ici soient nouveaux, entant qu'ils ne sont pas encore connus ou étalés par les Auteurs, qui on traité la Mécanique, on comprend néanmoins, que le fondement de ces principes ne saurait être nouveau, mais qu'il est absolument nécessaire, que ces principes soient déduits des première principes, ou plutôt des axiomes, sur le quels toute la doctrine du mouvement est établie.

A13 Definitio I. Quemadmodum Quies est perpetua in eodem loco permanentia, ita Motus est continua loci mutatio. Corpus scilicet, quod semper in eodem loco haerere observatur, quiescere dicetur:quod autem labente tempore in alia atque alia loca succedit, id moveri dicitur.

A14 Axioma I. Omne corpus, etiam sine respectu ad alia corpora, vel quiescit vel movetur, hoc est vel absolute quiescit vel absolute movetur.

A15 Axioma 2. Corpus, quod absolute quiescit, si nulli externae actioni fuerit subiectum, perpetuo in quiete perseverabit.

Axioma 3. Corpus, quod absolute movetur, si nulli externae actioni subiiciatur, secundum eandem directionem motu aequabili progredi perget.

A16 Definitio 11. Proprietas illa corporum, quae rationem perseverationis in eodem statu in se continet, inertia appellatur, quandoque etiam vis inertiae.

A17 Definitio 12. Qiucquid statum corporum absolutum mutare valet, id vis vocatur; quae ergo, cum corpus ob causas internas in statu suo esset permansurum, pro causa externa est habenda.

A18 Theorema 2a. Spatiola, per quae idem corpusuclum quiescens eodem tempusculo dt a diveris viribus promovetur, sunt ipsis viribus proportionalia.

A19 Theorema 3. Si aequales vires corpuscula inaequalia quiescentia sollicitent, effectus eodem tempusculo producti erunt reciproce inertiae corpusculorum proportionales.

A20 Definitio 15. Massa corporis vel quantitas materiae vocatur quantitas inertiae, quae in eo corpore inest, qua tam in statu suo perseverare quam omni mutationi reluctari conatur.

A21 Theorema 4. Si corpuscula ratione massae inaequalia quiescant atque a viribus quibuscunque singula sollicitentur, erunt spatiola, per quae eodem tempusculo protrudentur, in ratione composita ex directa virium in inversa massarum.

A22 Theoremate hoc ex solutione problematis invento primus est usus GALILAEUS ad motum gravium delabentium investigandum. Eius quidem demonstrationem non dedit, sed tamen propter insignem eius cum phaenomenis congruentiam de eo amplis dubitari noluit.

A23 Pro viribus ergo, quibus corpora iam mota sollicitantur, hanc dimetiendi rationem stabilimus, ut eas aequales iudicemus iis, quae in iisdem corporibus quiescentibus eodem tempore eundem effectum essent praestaturae. Haec autem ratio non indiget probatione, quia definitioni innititur nobisque adhuc liberum fuerat eam constituere. Si enim promotu quocunque spatiolas $s\sigma$ aequalia fuerint spatiola $S\sigma$, per quod idem corpusculum quiescens tempusculo eodem profertur a vi p, huic etiam illas vires aequales appellamus

A24 Quoniam autem immensi illius spatii cuiusque terminorum, [...] nullam nobis certam formare possimus ideam; loco huius immensi spatii eiusque terminorum considerare solemus spatium finitum, limitesque corporeos, ex quibus de corporum motu et quiete indicamus. Sic dicere solemus, corpus, quod respect horum limitum situm eundem conservat, quiescere, id vero, quod situm eodem respectu mutat, moveri.

A25 Wenn der Zuschauer gleichgeschwind in einer graden Linie fortrückt und die Gegenden richtig, das ist, nach gleichlaufenden Linien schätzet, so werden zur Unterhaltung der scheinbaren Bewegung, wie sehr dieselbe auch von der wahren unterschieden sein mag, eben diejenigen Kräfte erfordert, als zur Unterhaltung der wahren Bewegung.

A26 Wenn aber der Zuschauer sich nicht gleichförmig in einer graden Linie bewegt, dennoch aber die Gegenden richtig schätzet, so werden, um die scheinbare Bewegung aller Körper zu bewerkstelligen, noch ausser den Kräften, welche wirklich auf dieselben wirken, solche Kräfte erfordert, welche in einem jeden Körper alle Augenblicke eben die Veränderung hervorbringen, welche in dem Orte des Zuschauers vorgeht, aber nach einer umgekehrten Richtung.

A27 XXIV. C'est done de ce même grand principe, d'où il faudra dériver les regles, donc no us avons besoin pour determiner le mouvement d'un corps solide, lorsque l'axe de rotation ne demeure pas immobile. Pour cet effet il faudra considerer non seulement tous les élémens du corps, mais assi leur liaison mutuelle, en vertu de laquelle tous les élémens conservent entr'eux le meme ordre & les mêmes distances. Car le mouvement du corps entier est composé des mouvemens de tous ses élémens, & le mouvement de chacun doit suivre le principe, que je viens d'expliquer, entant que chaque élément

participe des forces qui agissent fur le corps, & qu'il est outre cela sollicité par de certaines forces, qui l'empêchent, qu'il n'abandonne la connéxion avec les autres. Or avant que de déterminer cet effet des forces, auxquelles les élémens sont assujettis, il faut considerer en general le mouvement, donc un eel corps en susceptible.

A28 Hic autem vires actu sollicitantes vicem causae gerunt, quam littera V designemus; deinde effectus est duplex: alter, quo motus corporis afficitur, cuius loco assumi debent vires elementares mutationem motus immediate efficientes, quas vires simul littera T denotemus. Alter vero effectus in conatu structuram corporis turbandi consistit, cuius loco sumi debent vires compagem afficientes, quas littera S notemus. Cum igitur a causa V producatur effectus $= T + S$, censeri debet $V = T + S$, unde colligitur $S = V - T$, prorsus uti invenimus. Verum in tanta rerum metaphysicarum caligine malim demonstrationem allatam adhibere ad principium metaphysicum illustrandum.

7 Conclusions

The justification by the scholars of the eighteenth century of the foundations of mechanics required substantial involvement in metaphysics and epistemology to introduce fundamental notions: the nature of space, time, force, constitution and properties of bodies, nature of motion. This effort was pursued by Euler not with the classical and organic approach of canonical philosophy but with the pragmatism of a mathematical philosopher. Euler's role in mechanics and philosophy has been overshadowed by the historians such as Mach, Dugas, Montucla, Dühring, very careful to the fundaments, who see him more as a mathematician than a mechanician or a philosopher. After all, more than 60% of his work deals with pure mathematics, and even those whose object is mechanics and astronomy contain many sections that can be classified as mathematics. Today Euler's role, even for what concerns the fundaments of mechanics, is reevaluated. Euler was lucky enough to be born in a period when all the mechanics and all the calculus were to build starting from the foundations of the seventeenth century. The section has showed that he used his luckiness however as much as fruitful it was possible.

Abstract

The language of the early calculus was much more geometrical than the analytic and algebraic style that was pioneered by Euler and still dominates today. For instance, functions such as $\sin(x)$ and $\log(x)$ were largely absent from the early calculus, with geometric paraphrases used in their place. From a modern standpoint, one may be inclined to assume that the eventual triumph of the more analytic perspective was a straightforward case of progress, and that the geometric aspects of the early calculus were a historical artifact ultimately hampering this development. Interestingly, however, in private notes, the pioneers of the calculus showed a readiness to disregard traditionalism and operate freely in a more proto-modern style than they allowed themselves in their publications. This suggests that the adherence to the geometrical mode in published works was a deliberate choice selected with full awareness of the analytic alternative. Indeed, the geometrical paradigm was no mere blind conservatism or lip service to classical foundations; rather, it arguably had genuine merits, for example, as an intuition-boosting heuristic strategy.

This aspect of the early calculus can serve as a case study that illuminates the relation between official expression and informal thought in mathematics more generally. For one thing, it complicates the common historiographic assumption that fidelity to historical thought is best achieved by following the original text's mode of expression as closely as possible.

Leibniz · Newton · Barrow · Euler · History of infinitesimal calculus · Fundamental theorem of calculus · Dimensional homogeneity · Anachronism · Historiography

1 Introduction

When studying a historical mathematical text, should we attempt to interpret it in terms of later mathematical concepts? Rampant anachronism can be a mark of insensitivity and a closed mind; it can drown out subtleties and rob us of one of the greatest rewards of studying history in the first place – that of expanding our own mindset and perspective. But banning all anachronistic analysis as illegitimate risks making historical scholarship conceptually impoverished and pathologically preoccupied with incidental details. The question is ultimately one that not only the historian but also the philosopher of mathematical practice must grapple with: Can a mathematician's written word be taken as constitutive of their underlying thought?

The early development of the infinitesimal calculus in the late seventeenth century provides a rich store of case studies for these questions. In addition to interesting differences between the original and modern forms of the calculus, we are fortunate that extensive personal manuscripts by the pioneers of the calculus have been preserved (and in many cases recently published for the first time), helping us further triangulate the relations between thought and expression, tradition and innovation.

2 Absence of Trigonometric Functions in Early Calculus

The early practitioners of the calculus virtually never used any trigonometric expressions such as $\sin(x)$ in their calculus. Neither Newton nor Leibniz ever wrote $\sin(x)$ in any calculus formula in any of their published works. They and many others did write expressions like this in purely geometric contexts, such as referring to sine tables. But they never treated $\sin(x)$ or any other trigonometric expression as a function in a calculus context. Unlike us, they did not see the differentiation and anti-differentiation of such expressions as among the most basic and commonly used calculation rules. They never described curves or solutions to differential equations in terms of such expressions.

How can this be, when any modern calculus textbook is packed with those kinds of uses of trigonometric functions? How can one have a functioning calculus without this tool? In fact, the early practitioners of the calculus were not in any way handicapped by this choice. Let us look at a few examples of how they managed without trigonometric functions. Let us consider some examples of problems where the treatment in a modern calculus textbook seems most essentially based on trigonometric functions, and see how Newton and Leibniz managed to treat these problems just as well, if not better, in other terms.

Simple harmonic motion – such as the bobbing motion of a weight on a spring – is a prototype example of a physical phenomenon described by a sine curve. The harmonic motion of a spring follows from Hooke's law that force is proportional to extension, $F \propto x$. Combined with Newton's law $F = ma = m\ddot{x}$, this means that the differential equation for the motion of the weight on the spring is $x = -k\ddot{x}$. Today, we would express the solutions to this equation in terms of sine and cosine functions. Yet in the seventeenth century people managed without it.

Newton dealt with this problem. Let's see how he did it. Newton considered a more general situation: motion in a force field where the force is proportional to distance from the origin, and directed toward the origin. This is analogous to a gravitational force field, but with a different force law. For any given starting position, a body can be launched into a circular orbit if it is given just the right sideways velocity. If the speed is increased or diminished by any amount, this would cause a deviation from the circular path (Fig. 1). Thus a specific orbital speed is naturally and intrinsically associated with this force field and this starting position.

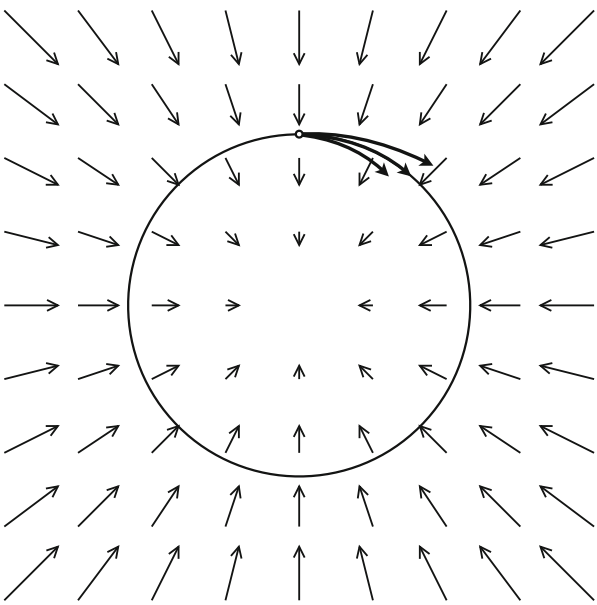

Fig. 1 Uniqueness of circular orbit through a given point in a $\mathbf{F} = -k\mathbf{r}$ force field

Table 1 Behavior of a body being dropped from $(x, y) = (0, R)$ in a $\mathbf{F} = -k\mathbf{r}$ force field

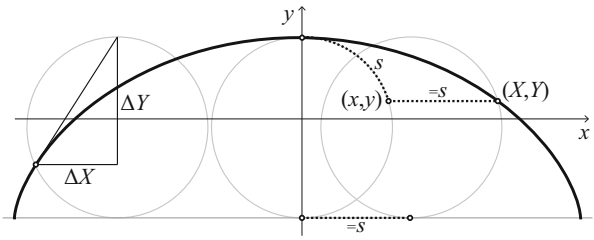
	Position at given time	Time to reach given position	Speed at given position
In terms of formulas	$y(t) = R\cos\left(\sqrt{k}t\right)$	$t(y) = \frac{\arccos\left(\frac{y}{R}\right)}{\sqrt{k}}$	$\dot{y}(y) = -\sqrt{k}R\sin\left(\arccos\left(\frac{y}{R}\right)\right)$
In terms of the associated circular-orbit motion	y-position of the orbital motion at that time 	Time in which orbital motion reaches that y 	y-direction speed of orbital motion at that y 
By taking this speed as a reference, one can describe harmonic motion in this field in a natural and precise way without the need for formulas.

This is precisely what Newton does in the *Principia*, Book I, Prop. 38, which is about the simple harmonic motion of a dropped object in a $F \propto r$ force field. He expresses everything in terms of the associated circular-orbit motion. Table 1 puts this approach side by side with the modern approach using formulas. Newton's way has a number of advantages. For instance, the equivalence of the three different results shown is immediately evident from the geometric descriptions but takes some algebra to derive from the formulas. Furthermore, Newton's mode of expression uses language intrinsic to the system itself: the naturally associated orbital motion. The formula approach, on the other hand, becomes ugly and opaque precisely because it uses extrinsic frames of reference. The constants k and R depend on our choice of units of force and position, and the trigonometric functions assume a unit radius and hence have to be scaled in various ways. Those are conventions that are external to the specific scenario at hand, yet they dominate the formulas. This is why the formulas are opaque and hide the simple dynamics of the system: the formulas are primarily focused on accommodating the system to a fixed external reference frame rather than on describing the system in the clearest and most intuitive terms.

Another example where modern calculus textbooks make trigonometric functions seem indispensable is the cycloid. "The only convenient way of representing a cycloid is by means of parametric equations," one standard textbook proclaims (Simmons 1996, 592). In the discussion that follows, the expressions sin and cos occur 40 times in the space of two pages, making the cycloid a good candidate for the most trig-intensive example in the standard calculus repertoire.

Leibniz did not think this was "the only convenient way of representing a cycloid." In fact, the very opposite is the case: Leibniz explicitly and repeatedly used the cycloid as his prime example of how "perfectly" the calculus could represent curves, but his representation is very different from the "only convenient" one of modern textbooks. In his very first paper on the integral calculus, he stresses that his "equation expresses the relation between the ordinate y and the abscissa x

Fig. 2 The cycloid



perfectly" and "from it all the properties of the cycloid can be derived" (Blåsjö 2017, 65).

Leibniz's "perfect" way of expressing the cycloid involves no trigonometry and no parametric equations. It is based instead on a simple geometrical property of the cycloid shown in Fig. 2: The three dashed lengths are all equal, since the arc s measures both the amount of rotation needed to bring the tracing point from the top position down to (x, y), and the amount of arc that has been in contact with the ground during this rotation, that is, the distance traveled, or the horizontal displacement $X - x$. Therefore an equation for the cycloid is $X = x + s$. This equation can be expanded, if desired, by expressing x using the Pythagorean Theorem and s as an arc-length integral. Assuming that the generating circle has unit radius, this gives

$$X(y) = x + s = \sqrt{1 - y^2} + \int_y^1 \sqrt{1 + \left(\frac{dx}{dy}\right)^2}\, dy = \sqrt{1 - y^2} + \int_y^1 \frac{dy}{\sqrt{1 - y^2}}$$

This is essentially Leibniz's "perfect" equation for the cycloid, except he centers his coordinate system on our $y = \ -\ 1$, so he gets the equivalent $\sqrt{2y - y^2} + \int dy/\sqrt{2y - y^2}$ instead.

Leibniz does not spell out how "all the properties of the cycloid can be derived" from this equation, but this can indeed be done. Let us consider how such an approach can lead to the same results that are derived using trigonometric expressions in modern textbooks such as Simmons (1996).

What is the area A of the cycloid, in terms of the area a of the generating circle? Integrating the equation $X = x + s$, we get

$$\frac{A}{2} = \int_{-1}^{1} X dy = \int_{-1}^{1} x dy + \int_{-1}^{1} s dy = \frac{a}{2} + [ys]_{y=-1}^{y=1} - \int_{-1}^{1} y \frac{ds}{dy} dy = \frac{3a}{2} + \int_0^{\pi} y ds$$
$$= \frac{3a}{2} + [x]_{s=0}^{s=\pi} = \frac{3a}{2}$$

so the area of the cycloid is three times the area of the generating circle, $A = 3a$. We see that Leibniz's equation for the cycloid indeed lends itself very well to calculation. The steps of this calculation do not correspond to the standard modern solution and

arguably compare favorably to it. A key ingredient of the modern proof is the use of a trigonometric addition formula to express $\cos^2(\theta)$ in terms of $\cos(2\theta)$. The Leibnizian proof does not need this technical machinery. The modern approach ultimately reduces the integral to the standard antiderivative $\int \cos(\theta)d\theta = \sin(\theta)$. The Leibnizian approach does the same thing in the step $\int yds = x$, which is nothing but a different way of saying $\int \cos(\theta)d\theta = \sin(\theta)$. Thus, the Leibnizian calculus contains the exact equivalent of our standard trigonometric derivatives and antiderivatives, but expresses them in other terms.

What is the tangent of the cycloid at any given point? In fact, the tangent passes through the top point of the rolling circle. This too is derived with quite elaborate trigonometric machinery in Simmons (1996) and other standard textbooks. From Leibniz's equation, we can get this result without any trigonometry. For we find that

$$\begin{aligned}\frac{d}{dy}X &= \frac{d}{dy}(x+s) = \frac{d}{dy}\left(\sqrt{1-y^2} + \int_y^1 \frac{dy}{\sqrt{1-y^2}}\right) \\ &= \frac{-y}{\sqrt{1-y^2}} - \frac{1}{\sqrt{1-y^2}} = \frac{-(1+y)}{\sqrt{1-y^2}} = \frac{-(1+y)\sqrt{1-y^2}}{1-y^2} = \frac{-\sqrt{1-y^2}}{1-y} = \frac{-x}{1-y}\end{aligned}$$

which indeed corresponds to $\frac{\Delta X}{\Delta Y}$ in the triangle in Fig. 2, as claimed. So, in this case too, the Leibnizian calculus handles the problem quite elegantly without any need for trigonometric functions. (In modern terms the differentiation of the integral $\int_y^1 dy/\sqrt{1-y^2}$ is nothing but the derivative of the arccosine, but re-expressing it in such terms adds nothing of value or substance.)

These examples show that although the calculus of Leibniz and Newton is different from ours, it should not be assumed inferior. Modern calculus books leave us with the impression that "the only convenient way of representing a cycloid is by means of parametric equations" involving trigonometric functions, and so on for various other problems such as harmonic oscillation. Seeing, then, that Newton and Leibniz used other methods, one may be inclined to assume that their methods are inherently clumsier, and that these historical mathematicians would have recognized as much on the spot if we explained it to them; the only reason they didn't take this step must have been that they were conceptually limited by old ways of thinking, one naturally assumes. But the above examples suggest that the sense of superiority of the anachronistic modern perspective is hubristic. There are in fact ways in which the older approach can not only readily match what the modern approach can do, but even has a number of outright advantages over it. This suggests that Newton and Leibniz may very well have adhered to their style of calculus as a matter of conscious choice, with full awareness of the possibility of a more formula- or function-based approach.

In fact, there is even one intriguing bit of direct textual support for this interpretation. Although trigonometric formulas are completely absent from all calculus publications for several decades from the inception of the calculus onwards, there is one obscure early manuscript in which Newton does precisely what the hypothesis of

a conceptual limitation postulated that he could not conceive: namely, he *does* use trigonometric formulas in calculus calculations, very much in the style of Euler or a modern textbook. In this manuscript from around 1680, Newton repeatedly writes "fl Cos A" – the fluxion of the cosine of the variable angle A – in the course of one particular problem (MS Add.3963.7, 55r; MP.IV.459). Despite seemingly never working with such expressions before or since, Newton handles them effortlessly and incorporates them in his calculations without ado. It seems that Newton opted for this mode of expression in this particular problem because of its complexity; the more geometric phrasing he normally used (including in the other problems in this very manuscript) would be very verbose in this case, which would probably impede the clarity and overview of the calculations. Thus, Newton seems to have treated "fl Cos A" as a trivial shorthand. This shows that there was certainly no conceptual obstacle that held Newton back from using such expressions more extensively. Clearly, he realized that calculus could be built on such expressions, but consciously opted against it.

3 Introduction of Trigonometric Functions by Euler

Trigonometric functions were eventually introduced into the standard calculus repertoire by Euler. As late as 1754, this was still referred to as the "new calculus of sines" (Katz 1987, 316; Euler *Opera* 1.14.543). The context that led Euler (1739) to introduce this "new calculus" was the differential equation

$$2a\ddot{s} + \frac{s}{b} + \frac{a}{g}\sin\left(\frac{t}{a}\right) = 0,$$

a periodically forced harmonic oscillator, whose solution is

$$s(t) = D\cos\left(\frac{t}{\sqrt{2ab}}\right) + C\sin\left(\frac{t}{\sqrt{2ab}}\right) - \frac{a^2 b\sin\left(\frac{t}{a}\right)}{g(a-2b)},$$

unless $2b = a$, in which case

$$s(t) = D\cos\left(\frac{t}{a}\right) + C\sin\left(\frac{t}{a}\right) + \frac{at}{4g}\cos\left(\frac{t}{a}\right).$$

Thus, unlike the simple harmonic oscillator that had long been handled by geometric paraphrase, the solutions of this differential equation involve combinations of trigonometric functions with different periods and trigonometric components multiplied by a nonconstant function (Fig. 3). The complexity of these solutions makes it very difficult to replace them with a geometrical description or to do without formulas of this type. As Euler put it, "there appear ... motions so diverse and astonishing that one is unable altogether to foresee until the calculation is finished" (Katz 1987, 318). Just as Newton had been led to use cosine formulas more

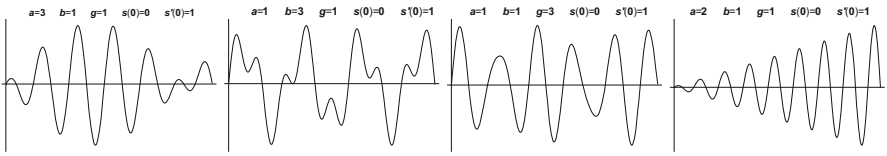


Fig. 3 Examples of solutions to the periodically forced harmonic oscillator considered by Euler (1739)

than half a century earlier in a particularly convoluted problem, so also to Euler the need to introduce such functions arises due to the complexity of the problem. In this way, it is possible to regard Euler's step not as a change in outlook, but merely as a consequence of the same priorities that were present even in Newton's time: the same outlook, consistently applied, leads to different styles in different contexts.

4 Logarithmic Functions

Just as trigonometric functions were absent from the early calculus, so was the logarithm function $\log(x)$. Despite explicitly dealing with the solution to the differential equation $\frac{dy}{dx} = \frac{a}{x}$ and referring to logarithmic curves by name in this connection, early calculus works by, for example, Leibniz (1684) and Johann Bernoulli (1692) refrain from using any kind of expression such as $\log(x)$ in a calculus setting. This could be interpreted as a shortcoming that hampered these works (Jahnke 2003, 111; Kowalewski 1914, 169). Interestingly, however, manuscript evidence shows that the reluctance to treat $\log(x)$ as one of the fundamental functions of the calculus cannot be attributed to an inability to conceive of the possibility of doing so. For Leibniz demonstrably did conceive of it years before, when he wrote "Log y" in a calculus formula in a 1675 manuscript (AA.VII.5.325). Clearly, then, his decision not to write any formulas involving $\log(x)$ even when dealing with problems involving logarithms must be considered a conscious choice rather than unreflective adherence to older modes of expression.

Despite these notable early absences, the logarithm function entered official calculus discourse much sooner than trigonometric functions. The first published use of a logarithm expression in a calculus formula appears to be Leibniz (1694, 369), who writes "log. x." Despite never having used this notation before in print, Leibniz simply starts using it *in media res* without any indication that he has expanded the core repertoire of calculus functions, and with no qualms about taking its properties (such as "log. $x = \int dx : x$") for granted as if they were common knowledge. This makes sense if he regarded "log. x" as a trivial shorthand for what was already well known in other (primarily verbal) terms.

Explicit uses of the logarithm function in calculus formulas did not catch on very quickly. Leibniz himself only used it passingly on one other occasion in print (Leibniz 1695, 314). Manfredi (1707), in what is effectively the first published integral calculus textbook, used the logarithm function quite extensively. Manfredi's

notation is "lx" for log(x). Johann Bernoulli also used this notation on a number of occasions, yet as late as 1716 he still felt the need to explain that "by *lx* I understand the logarithm of that x" (Bernoulli 1716, 228). Thus, even two decades after its first appearance in print, Johann Bernoulli evidently considered the logarithm as a calculus function still not fully established as an elementary part of the standard vocabulary and notation of the calculus.

To conclude, trigonometric and logarithmic functions are seen as an indispensable part of calculus today, but historically the calculus was up and running for a decade before the logarithm function was used in a calculus context, and half a century before trigonometric functions followed suit. This was not for lack of occasion to use such functions: on the contrary, plenty of situations in which we would use these functions were encountered, and often explicitly recognized as concerning trigonometric or logarithmic relations. But this was expressed in verbal and geometric prose, rather than by explicit formulas.

From a modern point of view, this may strike us as potentially a sign of a cognitive limitation: perhaps these early practitioners of the calculus were inhibited by an older geometrical and prosaic paradigm of mathematical thought that prevented them from embracing the power of a more modern formal and purely analytic approach. If we knew only the published works of these mathematicians, then the historical record could be construed as fitting this hypothesis. After all, the calculus community relatively soon decided to favor the analytic style rather than the original approach.

Nevertheless, a strong case can be made that this anachronistically tempting hypothesis misses the mark. Manuscript evidence shows that the analytic approach – in the form of explicit use of trigonometric and logarithmic expressions in calculus formulas – was in fact considered by the creators of the calculus at a very early date, even though they generally opted against this approach in their published works. Indeed, one could argue that the approach they did take was the one best suited for their purposes. The strength of the modern analytic approach over the older style lies especially in handling complicated relationships with many components and parameters. So instead of seeing the transition from geometric to analytic expression as one from ignorance to enlightenment, one can interpret it as the natural outcome of sound preferences that remained consistent throughout: the analytic approach was introduced precisely when the occasion called for it – that is, when the efficiency and generality of formula-crunching outweighed the intuitive appeal of geometric expression.

5 Dimensional Homogeneity

Requiring equations to be dimensionally homogenous was another geometrically motivated choice persistent in the early calculus but at odds with later analytic practice (Bos 1974, 7). Thus a "length" such as y cannot equal an "area" such as x^2, for instance, so one would rather write $ay = x^2$ to get a dimensionally balanced equation. This goes hand in hand with an emphasis on geometric interpretation

rather than analytic formulas. Thus, for example, Johann Bernoulli, in his calculus lectures of 1692, writes the differential equation for the exponential curve as $ydx = ady$, and when he separates the variables to $dx = ady : y$ he then proceeds, for the sake of geometrical interpretation, to explicitly multiply by a to get $adx = aady : y$, which he then interprets visually as an equality of areas (Johann Bernoulli *Opera* III.421; Blåsjö 2017, 84). Bernoulli describes the resulting curve verbally and geometrically as a "Logarithmica," but has no symbolic notation for this at this time. By contrast, Euler, in his calculus textbook, happily works with dimensionally unbalanced equations such as $dy = dx/x$ (Euler 1755, § 180) and treats them purely analytically.

But again it would be a mistake to think of the geometric conservatism of the early calculus as a limitation of thought. Just as Leibniz privately used analytic notation for logarithm functions, so also in early manuscripts he was much more lax about working with equations violating dimensional homogeneity than in his later published works (Bos 1974, 12; Leibniz AA VII.5.xxxvi). A 1694 letter by Johann Bernoulli (Leibniz AA III.6.167) is explicit about what was probably widespread practice: working with a differential equation, he finds that a certain expression "$=dy$" but then immediately adds: or for the sake of dimensional homogeneity "$=bdy$" where b is a new constant introduced solely to balance the equation dimensionally. That is to say, Bernoulli evidently had no problems working in an analytic mode that ignored formal geometric convention when expedient, only to then translate the end result into official form as a veritable afterthought. One finds the same type of reasoning in Leibniz's letters as well (Leibniz AA III.5.188).

This suggests that the convention of dimensional homogeneity was consciously adopted for the positive insights it could bring, without prejudice to other modes of reasoning. Indeed, dimensional analysis is a useful heuristic tool to this day (Pólya 1957, 202–205). Leibniz explicitly points out its usefulness as a check on calculations (AA VII.5.292). It was also very useful for purposes of geometric interpretation (the two examples from Bernoulli just mentioned are instances of this), which was often sensibly pursued in the early calculus as we have seen.

A related respect in which informal private practice was more flexible than formal expression was with regard to curve plotting. Impressively, accurate figures are quite common in the early calculus, but accompanying text is often couched in formal language quite aloof from the concrete, hands-on perspective that must have gone into producing the figures. Again, private manuscripts reveal a greater flexibility of thought than official discourse. Leibniz's description of the catenary $y = (e^x + e^{-x})/2$, for example, is in its published form rather stiltedly formulated in terms of the classical language of ratios. Privately, however, he operated with a more free-wheeling numerical approach, including using a decimal representation of e that he never revealed in print (Raugh and Probst 2019).

A similar example concerns how Jakob Bernoulli corrected his mistaken belief that the radius of curvature of any curve must be infinite at an inflection point. On intuitive grounds, Leibniz and Bernoulli had believed this to be a general principle. Indeed, it holds for simple inflection points, but there are exceptions. For instance, $x^3 = y^5$ has an inflection point at the origin, yet the radius of curvature there is zero.

This is because there are really multiple singularities in one at that point. Bernoulli deals with this by resolving the singularity. Instead of $x^3 = y^5$, consider $x^3 = y^5 - b^2y^3$ for small b. This pulls the singularities apart. Now, the inflection point at the origin is simple again and the general rule holds: infinite radius of curvature. Bernoulli published this finding, but it is interesting to compare his manuscript notes with the published account (Bernoulli 1999, 151–154, 255–258). First of all, it is striking that Bernoulli writes his equations in dimensionally homogenous form ($aax^3 = y^5$ and $aax^3 = y^5 - bby^3$) in his published article, but uses unbalanced equations ($x^3 = y^5$ and $x^3 = y^5 - bby^3$) in his private notes. Furthermore, in his notes Bernoulli used detailed numerical calculations to plot the curve and explore its behavior. A table of x and y values, computed to two decimal places, occurs right next to the figure. This is suppressed or deemed unworthy of inclusion in the published version, where the figure appears without such supporting calculations and the formal presentation gives the impression that the conclusions were reached by abstract reasoning in eminently classical form. The look behind the scenes, at the numerical curve plotting and visual checks in Bernoulli's private notebook, reminds us once again that official published expression can give a misleading impression of the underlying thought process.

6 Did Barrow Prove the Fundamental Theorem of Calculus?

Isaac Barrow (1670) proved certain geometric theorems that could be interpreted as equivalents of the fundamental theorem of calculus. Barrow was writing before the introduction of the concepts and symbolism of derivatives and integrals. He speaks in purely geometrical terms, such as areas and tangents of curves. Should he nevertheless be regarded as having had an insight effectively equivalent to the fundamental theorem of calculus? Some have answered yes (Child 1916, vii, 31; Heath 1917, 133; Nauenberg 2014, 343), and seem to have judged that the direct translatability of Barrow's theorems into this modern form is in and of itself a compelling reason to accept this conclusion. At the other extreme, some emphasize precisely the geometric form and absence of symbolism as a conclusive reason to deny Barrow this insight (Bos 1980, 64–65; Wagner 2001; Sonar 2018, 55). It is advisable to steer clear of both of these extremes when trying to understand the meaning and significance of historical texts. Though these two interpretations are opposites, they share an excessive emphasis on the statement of theorem and proof in isolation. A sounder approach is to investigate how these theorems functioned in Barrow's thought as a whole, and how he saw them fitting into a bigger picture. Historians who have taken such a perspective have tended to came down against the claim that Barrow's theorems are equivalent to the fundamental theorem of calculus (Whiteside 1961, 367–368; Mahoney 1990, 236; Katz 2009, 539).

When taking this balanced approach, the historian can use modernized notation with benefit, as a tool for clarification and analysis, without falling into either of the opposite traps of the "mathematician's" anachronistic naiveté and the "historian's" knee-jerk rejection of all anachronistic devices. Let us take Barrow's relation to the

fundamental theorem of calculus as a case study illustrating this methodology. Thus, we shall first translate Barrow's results into modernized form, while remaining agnostic as to whether this is a faithful representation of his thought or not. This will enable us to see what the global organization of Barrow's text says about how he viewed the theorems in question.

The fundamental theorem of calculus has two parts:

$$\frac{d}{dt}\int_a^t y(x)dx = y(t) \tag{FTC1}$$

$$\int_a^b y'(x)dx = y(b) - y(a) \tag{FTC2}$$

By choosing the coordinate system so that $y(0) = 0$ (which corresponds to Barrow's geometrical treatment), and using the notation $Y(x) = \int_0^x y(t)dt$, we can write this as

$$\frac{d}{dx}Y = y \tag{FTC1}$$

$$\int_0^x y'(t)dt = y(x) \tag{FTC2}$$

What we would interpret as results about derivatives, Barrow expresses in terms of subtangents and subnormals (i.e., the distance from the point where the tangent or normal cuts the axis to the point on the axis perpendicularly below the point on the curve in question; Fig. 4). In modernized language, the subtangent is $\sigma(y) = y/y'$ and the subnormal is $\eta(y) = yy'$.

The purported equivalent of FTC1 is Barrow's X.11. In our modernized form, it says $\sigma(Y) = Y/y$. Using the expression for the subtangent in terms of derivatives, we see that this is indeed equivalent to $Y' = y$, or FTC1. The question is: is this theorem, in Barrow's mind, tied to the specific geometrical configuration, or is it a more structural and general result that it would be natural to call upon in any situation when we seek the rate of change of any anti-derivative or accumulation function? Barrow's own text – and in particular his treatment of a polar version of X.11 – gives us strong reason to favor the former rather than the latter interpretation, as follows.

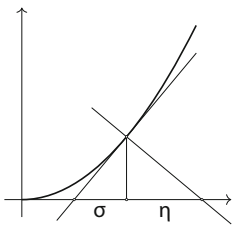

Fig. 4 The subtangent σ and subnormal η of a given curve

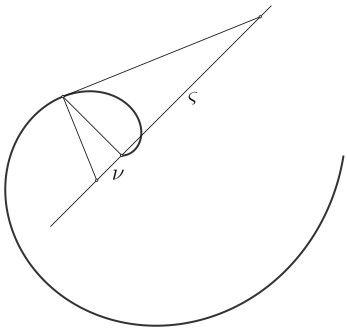

Fig. 5 The polar subtangent ς and polar subnormal ν

Throughout his treatise, Barrow interleaves results of the above form (in effect, assuming perpendicular rectilinear axes) with analogous results for curves defined in polar terms. In modernized form, $R(\theta) = \int_0^\theta (r(\vartheta))^2/2d\vartheta$ is the area-counting-function of the polar curve $r(\theta)$ (that is to say, $R(\theta)$ equals the area swept out by $r(\theta)$ from 0 to θ). For polar curves, the subnormal and subtangent are defined not as segments of the x-axis, but as segments of the line perpendicular to the radial line through the origin point (Fig. 5). The polar subtangent is $\varsigma(r) = r^2/r'$. The polar subnormal is $\nu(r) = r'$.

Barrow's Proposition X.13 is a polar analog of X.11. It says: For the tangent at the point where $r(\theta)$ and $R(\theta)$ intersect, $\varsigma(R) = 2$ (equivalently: $R' = R^2/2$). (Formally, the theorem only enables us to find the tangent at one particular point, but this is not an essential restriction. To find the tangent at another point on the curve $R(\theta)$, say where $R = kr$, we can let $\overline{r} = r/k$, and apply the theorem to the point of intersection of $\overline{r}(\theta)$ and $R(\theta)$, giving $\varsigma(R) = 2/k^2$.) Barrow proves X.13 from first principles, using the geometry of the polar differential triangle of $R(\theta)$. He presents X.13 as a "theorem of the same kind" as X.11, but he makes no use of the latter in the proof of X.13.

In modern terms, we could instead reason as follows. We know that $\varsigma(R) = R^2/R'$ for any polar curve from the geometry of the polar subtangent. In this case, $R(\theta)$ is the area-counting function of $r(\theta)$, which means that $R(\theta) = \int_0^\theta (r(\vartheta))^2/2d\vartheta$. We can easily find its derivative using FTC1. It is $R'(\theta) = r(\theta)^2/2$. So the polar subtangent is $\varsigma(R) = 2R^2/r(\theta)^2$. In particular, when $R = r$, this simplifies to $\varsigma(R) = 2$, which is Barrow's theorem X.13. This is a much shorter and easier proof than the elaborate deduction from first principles used by Barrow. The fact that Barrow did not use X.11 to prove X.13 in this way is thus quite compelling evidence that he lacked precisely that way of thinking about X.11 that warrants the FTC1 the epithet "fundamental."

Let us now turn to FTC2. In Lecture XI, Barrow presents "some Theorems ... relating to the Mensuration of Magnitudes by Tangents or Perpendiculars to Curves." That is to say, this lecture explains how to find areas in terms of tangents – or integrals in terms of derivatives. Indeed, we find a geometric equivalent of FTC2 in Barrow's XI.19. As in the case of FTC1, Barrow's statement and proof of

Table 2 Results proved by Barrow (1670) in modernized form

XI.1	$\int \eta dx = y^2/2$
XI.2	$\int \eta y dx = y^3/3$
XI.3	$\int \eta y^2 dx = y^4/4$
	$\int \eta y^3 dx = y^5/5$
XI.4	$\int Y y dx = Y^2/2$
XI.5	$\int \sqrt{Y} y dx = 2\sqrt{Y^3}/3$
XI.7	$\int \eta + x dx = \frac{1}{2}\sqrt{x^2 + y^2}^2$
XI.10	$\int \sigma dy = Y$
XI.12	$\int \sigma y dy = \int y^2 dx$
XI.13	$\int \sigma y^2 dy = \int y^3 dx$
XI.16	$\int \sigma^2 dy = \int \sigma y dx$
XI.17	$\int \sigma^3 dy = \int \sigma^2 y dx$
XI.19	$\int y' dx = y$
XI.20	$\int (y')^2 dx = \int y' dy$
XI.21	$\int (y')^3 dx = \int (y')^2 dy$

Theorem XI.19 could quite reasonably be construed as corresponding directly to FTC2. Unless one takes a fundamentalist zero-tolerance hardline against any interpretation that transcends surface expression, there is nothing in Barrow's formulation of XI.19 that explicitly indicates any essential conceptual difference between it and FTC2. In other words, Barrow's XI.19 *could* be thought of as a full-fledged FTC2. But the more interesting question is: *did* Barrow think of it this way?

To answer this question, we must not focus on XI.19 itself, but rather look at the context in which this theorem occurs. Much as in the case of FTC1, a contextual perspective strongly suggests that Barrow did not think of XI.19 as fundamental or a conceptual cornerstone of the entire chapter. Rather, he seems to have viewed it as one particular geometrical result among many of a similar kind. Excluding polar curves, the area results that Barrow presents in Lecture XI are shown in Table 2.

In modern terms, it is trivial to verify these results by substituting the respective derivative expressions for η and σ and using FTC2 as well as basic "Leibnizian algebra" with differentials such as $\frac{dy}{dx}dx = dy$.

Today, we think of FTC2 as much more generic and prototypical than the other theorems in Barrow's Lecture XI. But in the geometrical language used by Barrow, it does not have an evidently exceptional status. XI.19 is not any more generic than XI.1 or XI.10 or even XI.7, which has a very direct geometrical meaning since $\eta + x$ is the distance from origin to end of subnormal and $\sqrt{x^2 + y^2}$ is the distance from origin to the relevant point (x, y) on the graph of $y(x)$.

Barrow proves these results by direct area considerations and not by verifying by differentiation that the right-hand sides are antiderivatives of the integrands, as we would in light of FTC2. He never uses XI.19 for such a purpose. There is no indication that he conceived of the possibility of taking XI.19 to be the centerpiece of the theory

in this sense (or any other sense for that matter). Admittedly, XI.19 and its variations occur at the end of this sequence of results, which might suggest that it is the key result that crowns the entire development. Conceivably, Barrow might have perceived the fundamental nature of this result, yet opted to include and prove the previous theorems independently, perhaps for pedagogical, illustrative, or reference purposes. This possibility can be ruled out, however, by some revealing remarks later in the work.

In Appendix III to Lecture XII, Barrow offers a certain Theorem IV which he praises as "the most Fertile of all the Propositions foregoing. The greater Part of them being either contained in it, or deduced easily from it." The theorem in question may be considered a general result on change of variables. In slightly modernized terms, it states that if $y(x)$, $g(x)$, $h(y)$ are functions such that $\frac{\eta(y)}{y(x)} = \frac{h(y)}{g(x)}$ for all x (which in modern terms is equivalent to $g = y'h$) then $\int g dx = \int h dy$. Barrow notes the following special cases. If $h = 1$, we get XI.19. If $h = y$, we get XI.1. If $y = g$, we get XI.10. From this Barrow concludes: "I cannot but accuse my Foresight, for not having first laid down this Theorem . . . and then having deduced the rest from it, . . . which I observe may be done." This very strongly suggests that Barrow did not see the possibility of using his FTC2-equivalent XI.19 to unify the entire sequence of results in Lecture XI. He expressly admits that he would have loved to give such a unified treatment if he had seen a way of doing so. Only later did he realize that this was in fact possible, and even then he still did not see XI.19 as fundamental but rather saw the unification as coming from another theorem altogether that does not correspond to the modern view of the centrality of the FTC.

Thus, in the case of Barrow's purported equivalents of both FTC1 and FTC2, Barrow misses major opportunities to use them to do the kind of work that FTC1 and FTC2 would do for us. This suggests that Barrow's theorems should not be considered equivalent to FTC1 and FTC2. The mere fact that Barrow used geometrical language does not in and of itself entail this conclusion. On the contrary, the early pioneers of the calculus often used geometrical language similar to that of Barrow, yet showed no signs of being constrained in their thinking when the occasion called for formal, nongeometrical applications of calculus principles abstractly in ways that are not visualizable in terms of tangents and areas (e.g., Engelsman 1984, Chap. 2). Hence a similar surface form of expression can be in one case indicative of a genuine conceptual limitation and in another case not. Rather than focusing on the surface form in which an idea is expressed, attention to its functional role in the author's broader argument is a better indicator of which aspects of the form of expression are incidental or essential to the underlying thought. Reconstructions in modernized mathematical terms can be a useful tool for such purposes.

7 Conclusion

The early calculus used geometrical language and shunned the analytic style that came to predominate later. Many historians have tended to view this as a major conceptual divide (e.g., Speiser 2008, 108, 130). More mathematically inclined

scholars, however, have been inclined to push back against this perspective and perceive more continuity in the underlying ideas than the surface form of expression would suggest (e.g., Fraser 2020, 198). The examples from Newton, Leibniz, and Bernoulli analyzed above weigh in favor of the mathematical interpretation. With regard to Barrow's purported geometrical version of the fundamental theorem of calculus, on the other hand, we have a reverse state of affairs. Mathematically inclined readers have been those most ready to accept the equivalence, while the historians' perception of conceptual discontinuity is borne out by closer analysis.

In the former case, the mathematician's intuition was best supported by the historian's methods: The mathematician's sense that the early practitioners of the calculus did not lack the ability to reason in a manner functionally equivalent to the modern analytic approach is borne out by textual evidence that they indeed explicitly used more analytic approaches in private manuscripts that in many cases have only recently been published through meticulous efforts of specialized historians. Conversely, in the Barrow case, the historian's intuition is arguably best supported by the mathematician's methods: A thoroughly modernistic reconstruction of Barrow's reasoning, far from being tantamount to a simplistic anachronistic fallacy, makes a compelling case against accepting the equivalence of Barrow's theorems and their modern counterparts. Efforts to understand past mathematical thought are well served by drawing on the strengths of each these diverse perspectives and approaches.

Abstract

In this chapter, we offer a reconstruction of the evolution of Leibniz's thought concerning the problem of the infinite divisibility of bodies, the tension between actuality, unassignability, and syncategorematicity, and the closely related question of the possibility of infinitesimal quantities, both in physics and in mathematics.

Some scholars have argued that syncategorematicity is a mature acquisition, to which Leibniz resorts to solve the question of his infinitesimals – namely the idea that infinitesimals are just signs for Archimedean exhaustions, and their unassignability is a nominalist maneuver. On the contrary, we show that syncategorematicity, as a traditional idea of classical scholasticism, is a feature of young Leibniz's thinking, from which he moves away in order to solve the same problem, as he gains mathematical knowledge.

We have divided Leibniz's path toward his mature view of infinitesimals into five phases, which are especially significant for reconstructing the entire evolution. In our reconstruction, an important role is played by Leibniz's text *De Quadratura Arithmetica*. Based on this and other texts, we dispute the thesis that fictionality coincides with syncategorematicity, and that unassignability can be bypassed. (In this chapter, we employ "syncategorematic" as a shorthand for "eventually identifiable with a procedure of exhaustion" and, as a consequence, "involving only assignable quantities." We also identify syncategorematicity with potentiality, as suggested by some part of the scholastics, and in Sect. 2.2, we show that the two characterizations are equivalent, provided that "potentiality" is intended in the correct way: namely as in the unending iterative procedures of Greek mathematics.) On the contrary, we maintain that unassignability, as incompatible with the principle of harmony, is the ultimate reason for the fictionality of infinitesimals.

Keywords

Infinite divisibility · Infinitesimals · Infinita terminata · Potential infinity · Syncategoremata · Fictionality · Unassignability · Leibnizian metaphysics

1 Introduction

Leibniz's thinking about infinitely small quantities underwent a complex evolution, both from the mathematical and from the epistemological point of view.

In his maturity, Leibniz was aware of the difficulties that the notion of an infinitely small quantity raises, but his writings suggest that his epistemological awareness has matured as a result of his mathematical proficiency. While the young Leibniz applied almost naively in physics the new mathematical discoveries of his time, of which he had only a superficial knowledge, in his maturity, he develops a more complex view of the relationship between mathematics and physics (and metaphysics), and becomes more cautious both in the application and in the definition of mathematical notions.

In particular, Leibniz eventually comes to master the notion of unassignability and the consequences it involves. This leads him to a cogent treatment of infinitesimals in mathematics – infinitesimals are noncontradictory notions – and to a rejection in physics – they are incompatible with the principle of harmony. In other words, this leads Leibniz to his mature view of infinitesimals as accidental impossibilities, or "well-founded fictions."

We have divided Leibniz's path toward this position into five phases, which can be roughly summarized as follows.

The young Leibniz shares with many contemporary philosophers both a scholastic background and the need of correcting it in the wake of the modern mechanistic philosophy. At this stage, Leibniz's thought does not require infinitely small quantities, for both in mathematics and in physics, he adopts a traditional syncategorematic approach: both extension and matter are continuous, which means that they are

potentially infinitely divisible, and every obtained part is assignable. Take a continuous quantity – for instance, a segment – you can divide it, and then divide it, and then divide it. . . and so on, indefinitely. Since the procedure has no end, no ultimate constituents can be reached, in either mathematics or physics, and since the quantity obtained at every step of the procedure is smaller than the one obtained at the previous step, but is nonetheless finite, no unassignable infinitesimal quantities can be reached, either (phase I: 1668–1669).

Quite early, for metaphysical reasons and in opposition to Descartes, the question of the ultimate constituents of physical bodies becomes a matter of primary importance for Leibniz. However, the solution he offers before his stay in Paris – marking the start of Leibniz's mathematical training and his acquaintance with the contemporary debate – is a very problematic one. At the very beginning (phase II: 1670–1671), Leibniz simply redefines matter as a continuous stuff infinitely divided – and not only divisible – into parts. Both actuality and unity of these parts are due to their *conatus*, or unextended amounts of motion. The geometrical counterpart of this physical situation is a hybrid in which the infinite divisibility of the continuum has to coexist with the actuality of unextended "fat points," which Leibniz identifies with Cavalieri's indivisibles. In this phase, unassignability is accepted, without any further elaboration.

In the first years of the Parisian stay (phase III: 1672–1674), a slightly modified version of this solution is devised, which seems to solve the problem of actuality in physics but still raises difficulties in mathematics.[1] The core idea is to put discreteness before continuity: physical bodies do not come from an infinitely divided continuous stuff but from the aggregation of discrete basic elements. As in phase II, the ultimate elements are actually infinite and "glued" together by their *conatus* of motion. In mathematics too, the situation is similar, with the only difference that now points are extended, although unassignable. Apparently, in this phase, to keep together extended but unassignable quantities and assignable ones is not a problem for Leibniz. Unassignable quantities are not called fictions, nor referred to using cognate verbal forms.

Only towards the end of his stay in Paris, Leibniz becomes aware of the existence of a problem, as the notes he wrote in phase IV (1675–1676) show, as well as his further writings. In particular, Leibniz rejects the possibility that physical quantities are not all comparable to each other: a world containing some portion of matter which has an unassignable ratio to another portion would be less perfect than a world where all portions are comparable.

For this reason, the solution Leibniz offers in this period to the problem of the composition of physical bodies is only apparently similar to the one described in phase III. In both cases, we have an infinitely divided material stuff and a sort of glue that keeps the parts together, but while in phase III the glue, namely the *conatus* of motion, corresponded to physical objects, in phase IV, material parts are held together by metaphysical bonds. In other words, in phase III, a geometrical description was needed, which did contain both the parts of a body, which are assignable, although infinitely divisible, and their unassignable *conatus*. In phase IV, instead, a

[1] See further in note 21.

geometrical description is needed only for the assignable physical parts, while the metaphysical "cement" is no longer constrained.

It is exactly in phase IV that Leibniz starts referring to unassignable quantities as "fictions" and links them to other "imaginary" notions, such as imaginary numbers, that are noncontradictory but do not admit any traditional geometrical representation.

Finally (phase V: 1677– ...) the separation between mathematics, physics, and metaphysics is gradually brought to completion. In particular, mathematics ceases to be the foundation of physics, and geometry ceases to be its natural description: the true essence of physics is metaphysics, and as such it is non-representable. In particular, being extraneous to the category of quantity, metaphysical objects can be thought of as unassignable in a stronger sense and without problematic consequences.

2 The Quest for Actuality

2.1 Actuality and the Ultimate Elements of Physics

In the very first years of his philosophical career, here described as phase I, Leibniz still operates in a scholastic context, where physical objects are continuous and continuity implies potentiality, by definition. But as soon as he begins to develop his own positions, the need to go beyond potentiality, grounding physical objects on something actual, becomes a key feature of Leibniz's philosophy.

The search for actuality, however, is forced to coexist with another crucial feature, namely the infinite divisibility of matter, which Leibniz inherits from scholasticism and will never abandon. The tension between these two seemingly irreconcilable positions, combined with a firm belief in keeping metaphysics out of physics, is what characterizes Leibniz's first moves towards an original theory of physical substance.

In the early 1670s, here described as phases II and III, we witness Leibniz's first unsuccessful attempts to conciliate actuality and infinite divisibility, without resorting to metaphysics. The idea was to locate actuality in some ultimate elements of matter, making it derive not from a vague metaphysical form, but from a much more concrete, and mathematically manageable, (tendency to) motion. In Leibniz's intentions, by virtue of their motion, the ultimate parts of a physical body should be able to stay connected together, as a whole, while maintaining their individuality. But neither the continuous parts of phase II nor the discrete atoms of phase III were up to the task.

At this point, Leibniz shifts his attention from material parts to their connections, namely their tendencies to motion, or *conatus*, whose inherent actuality makes them appear a better candidate to ground physical substances. Moreover, having been defined as unassignable, it seemed natural to interpret the *conatus* as the physical counterpart of mathematical indivisibles, a topic that had captured the attention of Leibniz.

From the writings of this period, however, it is not clear how, and to what extent, the elimination of any material constituent can be finally implemented. Also, the question of the coexistence of unassignable and assignable quantities is left unanswered. Probably unsatisfied by this incomplete picture, starting from the last years of his stay in Paris, here described as phase IV, Leibniz changes his approach: he

dismisses the search for infinitesimal actual elements in physical bodies and looks elsewhere to find the source of the actuality he needs.

More generally, he dismisses the search for any mathematical quantitative causes in physics, and turns to metaphysics, leaving to mathematics the (approximate) description of the phenomenal realm of nature, but not its causal explanation.

In the following subsection, we analyze in more detail the notions of syncategorematicity and potentiality, and their relationship as conceived in the scholastic logic.

2.2 Syncategorematicity and Potentiality

The distinction between categorematic and syncategorematic infinite has a grammatical origin. C*ategoremata* were the parts of speech which possess a definite meaning of their own. *Syncategoremata* were such parts as depend on *categoremata* in order to acquire a definite meaning.[2]

Although in grammar *syncategoremata* and *categoremata* formed two mutually exclusive and collectively exhaustive classes, the notion of *syncategorema* was imported to logic, with a broadened range of application. For medieval logicians, a *syncategorema* is a term that has a signification, but an indefinite one, and can be defined by the presence of other words.

In this context, a *categorema* can be employed in a "syncategorematic" way, and the distinction between categorematic and syncategorematic use of the same term becomes one of the standard ways of solving *sophismata*, namely puzzling sentences, that can be true or false depending on the interpretation of their parts.

The sentence "unlimited are limited" (*infinita sunt finita*) was a paradigmatic example of such a puzzle. The way of solving it by resorting to the opposition categorematic/syncategorematic made the distinction between categorematic and syncategorematic (use of the word) infinite a very common one.

Given the traditional Aristotelian distinction between actual and potential infinite, meant as philosophical notions, it is not surprising that the logico-grammatical level and the philosophical one became conflated, leading to talk about a categorematic and a syncategorematic infinite *tout court*. This is so, especially since the logicians themselves, introducing the grammatical distinction, referred to Aristotle's philosophical discussion of the infinite.

At least, this is the case of Peter of Spain, whose *Summulae Logicales* (Peter of Spain 2014), written in the second quarter of the thirteenth century, became the most influential introduction to logic of the late Middle Ages. Peter deals with the infinite in the last treatise of the book, devoted to distributions (*distributiones*). As we read in chapter 1:

[2]Both the distinction and the term *syncategoremata* appear in the *Institutiones grammaticae*, written at the beginning of sixth century by the Latin grammarian Priscian and well known in the Middle Ages. On syncategoremata in grammar and in logic, see in particular Kretzmann (1982).

> **[P1]** Distribution is the multiplication of a common term produced by a universal sign. When someone says 'every man,' for example, that term 'man' is distributed or confused for whatever is below it by this sign 'every,' and so in this case there is multiplication of a common term. [*Summulae Logicales* XII.1 Transl. Copenhaver][3]

After a short introduction, Peter discusses the most important distributive signs and distinguishes them as *distributive of substance*: every, nothing, whole... and *distributive of accidents* (quality and quantity).

The infinite is the last among the signs distributive of quantity. Peter starts his discussion explaining the diverse meanings of the term "infinite" in philosophy. He quotes Aristotle's *Physics* almost verbatim[4]:

> **[P2]** Next comes the name 'infinite' which is said in five ways. In one way, the infinite is said to be what cannot be crossed-over – as a word is said to be infinite as to sight because it is invisible, since it is not naturally suited to be seen. In another way, the infinite is said to be what is incompletely crossed in that it has not yet been crossed, even though it is naturally suited to be crossed, as when someone is crossing a space and has not yet come to its limit.
>
> In a third way, the infinite is said to be in regard to succession, as an augmentable number is infinite when succeeded by unity or by another number. But in a fourth way it is in regard to division, like the continuous, for everything continuous is divisible without limit. Hence, it is defined by Aristotle in the sixth book of the *Physics* as follows: "the continuum is divisible into what is always divisible."[5] And in a fifth way, the infinite is said in both those senses, by addition and by division, like time. For since time is continuous, it is divisible without limit, and in this way, it is infinite by division, and since one time comes after another time, in that way, by the addition of one time to another, it is infinite by addition. [*Summulae Logicales* XII.36 Transl. Copenhaver, with changes][6]

The first two ways of saying that something is infinite are in fact improper ways of speaking (as Aristotle himself explains), which Peter does not consider. He discusses the proper senses of the term, focusing on their crucial common feature: namely their being defined in an iterative way:

---

[3] "Distributio est multiplicatio termini communis per signum universale facta. Ut cum dicitur omnis homo, iste terminus homo distribuitur sive confunditur pro quolibet suo inferiori per hoc signum omnis, et sic est ibi multiplicatio termini communis."

[4] *Physics* III 4, 204a2–7.

[5] *Physics* VI 2, 232b24–25.

[6] "Sequitur de hoc nomine infinitum, quod dicitur quinque modis. Uno enim modo dicitur infinitum quod non potest pertransiri—ut vox dicitur infinita quoad visum quia est invisibilis, quia non est apta nata videri. Alio autem modo dicitur infinitum quod habet transitum imperfectum eoquod nondum transitum est, tamen est aptum natum transiri, ut cum aliquis transit spatium et nondum venit ad finem eius. Tertio modo dicitur infinitum secundum appositionem, ut numerus augmentabilis est infinitus appositione unitatis vel alterius numeri. Quarto autem modo secundum divisionem, ut continuum, omne enim continuum divisibile est in infinitum. Unde diffinitur ab Aristotile in sexto *Phisicorum* sic: continuum est divisibile in semper divisibilia. Quinto autem modo dicitur infinitum utroque modo, scilicet appositione et divisione, ut tempus. Cum enim sit continuum, est divisibile infinitum, et sic est infinitum divisione, et cum post unum tempus veniat aliud tempus, sic per appositionem temporis unius ad aliud est infinitum appositione."

[P3] And as to these last three significations, the definition goes this way: the infinite is that whose quantity – for items that take quantity – can always get something more, so that if, after one part of a line, another part was taken on, and after that, a third, and the end of it could never be reached, then the line would be called 'infinite'. [*Summulae Logicales* XII.36 Transl. Copenhaver, with minor changes][7]

Here the reference is to Aristotle's definition of potential infinite:

[A] the infinite is in virtue of another and another thing being taken, over and over again; and what is taken is finite, over and over again; but it is a different thing, over and over again. [*Physics* III 6, 206a27–29. Translation ours][8]

Then Peter comes to the dialectical parts of his discussion and explains how infinite can be used both for a common and for a distributive term:

[P4] But the usual claim is that the infinite is sometimes used for a common term, and then this proposition: "infinite are finite" is equipollent with this one "some infinite are finite". Sometimes, however, it is used for a distributive term, and then the former "infinite are finite" is equipollent as to distribution with this one: "the-more than-whatever are finite". And it is confirmed in this way: "the-more than-one are finite; the-more than-two are finite; the-more than-three are finite" and so on for others; "therefore, the-more than-whatever are finite".

And then this is said to produce an 'inter-laddered' distribution (or else interrupted or discontinuous) because this word 'more' in the first proposition stands for two and beyond, in the second for three and beyond, and in this way, it keeps going higher step by step, or like a ladder. And therefore, the phrase 'more than whatever' produces an inter-laddered distribution because my term 'whatever' stands for some things and my term 'more' for others, as it goes higher numerically—as has been said [*Summulae Logicales* XII.37 Transl. Copenhaver, with minor changes][9]

Finally, summarizing the solution of the sophisma, Peter maintains the equivalence between syncategorematic and distributive use of the term "infinite":

[7] "Et quoad has tres significationes ultimas diffinitur sic: infinitum est cuius quantitatem accipientibus semper est sumere aliquid extra, ut si post unam partem linee accipiatur alia, et post illam tertiam, et numquam posset attingi terminus eius, tunc linea diceretur infinita."

[8] ὅλως μὲν γὰρ οὕτως ἔστιν τὸ ἄπειρον, τῷ ἀεὶ ἄλλο καὶ ἄλλο λαμβάνεσθαι, καὶ τὸ λαμβανόμενον μὲν ἀεὶ εἶναι πεπερασμένον, ἀλλ᾽ ἀεί γε ἕτερον καὶ ἕτερον

[9] "Solet autem poni quod infinitum quandoque sumitur pro termino communi, et tunc hec propositio, 'infinita sunt finita', equipollet huic 'aliqua infinita sunt finita' Quandoque autem sumitur pro signo distributive, et tunc ista, 'infinita sunt finita', equipollet huic quoad distributionem, scilicet 'quolibet plura sunt finita'. Et probatur sic: 'Uno plura sunt finita'; 'duobus plura sunt finita'; 'tribus plura sunt finita', et sic de aliis; ergo 'quolibet plura sunt finita'. Et tunc dicitur facere interscalarem distributionem (sive interruptam vel discontinuant) quia hec dictio plura in prima propositione supponit pro duobus et deinceps, et in secunda pro tribus et deinceps, et sic semper gradatim sive scalariter ascendendo. Et ideo hec oratio quolibet plura facit interscalarem distributionem quia pro aliis supponit hoc quod dico quolibet et pro aliis hoc quod dico plura, secundum numerum ascendendo—ut dictum est."

> **[P5]** A distinction made by others is that 'infinite' can be a common term, and in this way the original proposition is false; or else it can be a syncategorematic expression that in itself indicates distribution, as has been said, and in that way, they claim that the original proposition is true. [*Summulae Logicales* XII.38 Transl. Copenhaver, with minor changes][10]

In Peter's exposition, the relation is clear, between the syncategorematic infinite, i.e., the infinite used for a distributive term, and the infinite in regard to addition, or to division, as described in **[P3]**: namely Aristotle's potential infinite, as defined in **[A]**.

But while there is a general agreement concerning the identification of syncategorematicity with distributivity, scholars are divided on the possibility of equating syncategorematic and potential infinite.[11] This depends on the interpretation of Aristotle's definition of potential infinite: once the particular kind of potentiality Aristotle ascribes to the infinite is correctly understood, as in Peter's analysis, the identification with syncategorematicity is straightforward. On the contrary, no similarity can be detected between the two notions if one tries to ascribe to the infinite the "standard" notion of potentiality: namely the one Aristotle usually deploys, and contrasts with actuality, when he speaks of objects, but explicitly prevents from using in the case of the infinite:

> We must not take potentiality here in the same way as that in which, if it is possible for this to be a statue, it actually will be a statue, and suppose that there is an infinite which will be in actuality [*Ph*. III 6, 206a18–20. Translation ours][12]

But then, what is the peculiar meaning Aristotle assigns to the notion of potentiality in the phrase "potential infinite"? The answer is in the definition itself:

[10] "Alii distinguunt eoquod infinitum potest esse terminus communis, et sic prima est falsa; vel potest esse dictio sincathegorematica importans in se distributionem, ut dictum est, et sic ponunt ipsam esse veram."

[11] It is worth noting that scholars who deny any connection between syncategorematicity and potentiality ascribe this position to Peter of Spain, unfortunately without any further specification. Uckelman (2015), p. 2368, for instance, says that: "it is clear that the syncategorematic/categorematic and the potential/actual distinctions are simply not of the same sort [. . .] in agreement with Peter of Spain, who, according to Moore, explicitly rejected any coincidence between the two distinctions (Moore 1990, p. 51)." But Moore (1990) simply states that: "Peter had explicitly denied any coincidence," giving no reference. In fact, a passage from the treatise *De exponibilibus* was quoted with the same intent by Duhem (1913) (VII p. 61. Translated in Duhem 1985, p. 50) who mistakenly attributed it to Peter. The inauthentic *De exponibilibus* is not included in De Rijk's edition of Peter's *Treatises* and maybe for this reason modern commentators who deny the relation syncategorematic/potential cannot give an exact reference for their key passage. In general, on the distinction, and on the identification syncategorematic/potential and categorematic/actual, see, for example, Kretzmann (1982). On the meaning of syncategorematicity in Leibniz, see Antognazza (2015) and Ugaglia (2022). On the iterative reading of potentiality and its connections with Greek proofs by exhaustion, see Ugaglia (2009, 2018).

[12] οὐ δεῖ δὲ τὸ δυνάμει ὂν λαμβάνειν, ὥσπερ εἰ δυνατὸν τοῦτ᾽ ἀνδριάντα εἶναι, ὡς καὶ ἔσται τοῦτ᾽ ἀνδριάς, οὕτω καὶ ἄπειρον ὃ ἔσται ἐνεργείᾳ·

> **[A]** the infinite is in virtue of (**A1**) another and another thing being taken, over and over again (*aei*); and (**A2**) what is taken is finite, over and over again (*aei*); but (**A3**) it is a different thing, over and over again (*aei*). [*Physics* III 6, 206a27–29. Translation ours][13]

As is clear, and as was clear to Peter of Spain, **[A]** is not a conventional Aristotelian definition, but an operational characterization. It does not describe an object but an action – "taking" something – and the iteration of the action, signaled by the adverb *aei*. For each thing we take (*first step*), there is another thing to take (*second step*), and another to take beyond that (*third step*), and another beyond, and so on, over and over again (*aei, next steps*).

Once the potential infinite is understood in this way, it is immediate to interpret it as "a syncategorematic expression that in itself indicates distribution" to use Peter's words.[14] In fact, as he explains in **[P4]**, if the term "infinite" is used in this sense, the sentence "infinite are finite" can be rephrased as: "the-more than-one are finite (*first step*); the-more than-two are finite (*second step*); the-more than-three are finite (*third step*) and so on for others (et sic de aliis, *next steps*)."[15]

3 Leibniz's Trajectory in Five Phases

3.1 An Overview

Leibniz's mature position concerning the ultimate composition of bodies, and the related issue of their division, is rather clear (see Sect. 3.2.5). It is part of an articulated philosophical construction, embracing mathematics, physics, and metaphysics, that can be summarized as follows.

Since a complete separation exists between the ideal realm of mathematics, the phenomenal realm of physics, and the true realm of metaphysics, a completely different solution is offered to the problem in the three contexts.

Metaphysical real entities are indivisible unextended unitary wholes, which do not admit division of any kind. However, these substances, as any other metaphysical notion, are unknowable and inaccessible per se. As unknowable, in particular, and extraneous to the category of quantity, they can be described only through

[13] See note 9 for the Greek text. The condition **A3** has the only aim of discriminating between procedures that are infinite in a proper sense and procedures that are infinite because they are periodic. In the latter case, one comes back to something already taken after a certain number of steps.

[14] See also William of Sherwood's *Syncategoremata*, where the infinite in its syncategorematic significance is explicitly related to induction (O'Donnell 54–55, translated in Kretzmann 42–43).

[15] The sophisma itself "infinite are finite" is nothing but a deliberately equivocal way of restating Aristotle's condition **A2**.

analogical speech; as inaccessible, they can be approached only through their phenomenal "expressions," namely physical bodies.[16]

Physical bodies are extended and composed of extended parts. These parts are actually infinite, but only in this sense: there is no part that is not actually subdivided into others:

> It is perfectly correct to say that there is an infinity of things, i.e., that there are always more than one can specify. But it is easy to demonstrate that there is no infinite number, nor any infinite line or other infinite quantity, if these are taken to be genuine wholes. The Scholastics were taking that view, or should have been doing so, when they allowed a 'syncategorematic' infinite, as they called it, but not a 'categorematic' one. [*Nouveaux essais sur l'entendement humain*, II. XVII. A6.6 157. Transl. Remnant-Bennet][17]

Moreover, the parts of a physical body do not form a continuous magnitude, but only a contiguous one. Here one must note that neither the notion of actual infinity employed in physics – also known in literature as "syncategorematic actual" – nor that of contiguity are mathematical notions.[18]

In fact, in mathematics, Leibniz maintains his traditional genuinely syncategorematic characterization of continuity as potentially infinite divisibility, which means that the parts into which a geometrical continuum can be divided are only potential:

> As for the first point, it follows from the very fact that a mathematical body cannot be analyzed into primary constituents that it is also not real but something mental and designates nothing but the possibility of parts, not something actual. A mathematical line, namely, is in this respect like arithmetical unity; in both cases the parts are only possible and completely indefinite. A line is no more an aggregate of the lines into which it can be cut than unity is the aggregate of the fractions into which it can be split up. [. . .]
>
> But in real things, that is, bodies, the parts are not indefinite – as they are in space, which is a mental thing – but actually specified in a fixed way according to the divisions and subdivisions which nature actually introduces through the varieties of motion. And granted that these divisions proceed to infinity, they are nevertheless the result of fixed primary constituents or real unities, though infinite in number. Accurately speaking, however, matter

[16] The notion of "expression" is repeatedly discussed throughout the correspondence with Arnauld from September 1687 [A2.2. 230–8].

[17] "A proprement parler, il est vrai qu'il y a une infinité de choses, c'est à dire qu'il y en a tousjours plus qu'on n'en peut assigner. Mais il n'y a point de nombre infini ny de ligne ou autre quantité infinie, si on les prend pour des veritables Touts, comme il est aisé de demonstrer. Les écoles ont voulu ou dû dire cela, en admettant un infini syncategorematique, comme elles parlent, et non pas l'infini categorematique."

[18] On the expression "syncategorematic actual" for denoting Leibniz's physical infinite, which is currently employed in Leibnizian studies, see Arthur (2015, 145). It has been defended as an innovative mathematical notion, for instance, in Arthur (2019), criticized on that point in Bussotti (2019). On the mathematical inconsistency of Leibniz's physical notion of infinite, see also Ugaglia (2022).

> is not composed of these constitutive unities but results from them. [*Leibniz to De Volder* June 30 1704; G II, 268. Transl. Loemker][19]

Despite the differences, both in physics and in mathematics, no infinitesimal unassignable quantities can be reached while proceeding with the division: the quantity obtained at any step, in fact, is in a given and finite ratio with the one obtained at the previous step, and with the one obtained at the next one.

But while to postulate the existence of infinitesimal quantities in physics could raise some difficulties,[20] the introduction of infinitesimal quantities in mathematics does not carry such risks and is highly useful. Although they do not follow Euclid V Definition 4 and do not admit a traditional geometrical representation, Leibniz provides rules that make his unassignable infinitesimals mathematically sound, noncontradictory objects.[21]

In other words, while geometrical curves are continuous, namely indefinitely divisible into potential parts, the problems they represent can be solved by using infinitesimal quantities. Moreover, the language of infinitesimals turns out to be useful in speaking, analogically, of some metaphysical objects.

The situation is similar to that with imaginary numbers, which at Leibniz's time had neither a geometrical representation nor a physical counterpart, but were well-defined, noncontradictory, and useful mathematical notions. And in fact, as for

[19] "Quod primum attinet, eo ipso quod corpus mathematicum non potest resolvi in prima constitutiva, id utique non esse reale colligatur, sed mentale quiddam nec aliud designans quam possibilitatem partium, non aliquid actuale. Nempe linea mathematica se habet ut unitas arithmetica, et utrobique partes non sunt nisi possibiles et prorsus indefinitae; et non magis linea est aggregatum linearum in quas secari potest, quam unitas est aggregatum fractionum in quas potest discerpi [. . .] At in realibus, nempe corporibus, partes non sunt indefinitae (ut in spatio, re mentali), sed actu assignatae certo modo, prout natura divisiones et subdivisiones actu secundum motuum varietates instituit, et licet eae divisiones procedant in infinitum, non ideo tamen minus omnia resultant ex certis primis constitutivis seu unitatibus realibus, sed numero infinitis. Accurate autem loquendo materia non componitur ex unitatibus constitutivis, sed ex iis resultat."

[20] Even if the existence of infinitesimal quantities in physics is not an absolute impossibility – namely it does not involve any contradiction – it is contrary to the harmony of things. In fact, a world containing "some portion of matter which has an unassignable ratio to another portion" would be less perfect than a world where all portions are comparable. On this point, it is interesting to read the 1698 correspondence between Leibniz and Bernoulli, vigorous proponent of the existence of infinitesimal quantities in physics. In particular, in his letter of July 5, 1698 (GM III 503–504), Bernoulli asks why only a size (*gradus*) of infinity is allowed, namely the one proportionate to our intellect, and not the infinite others (he means here infinitesimals and higher degree of infinitesimals dx, ddx. . .). In his answer of July 12, Leibniz replies that: "from the actual division it follows that in every part of matter, there is a world – so to speak – made of innumerable creatures; but we ask if there is some portion of matter which has an unassignable ratio to another portion, or if there is a line bounded (terminata) on both ends, having an infinite or an infinitely small ratio, to another line. We assume that in our Calculus, fruitfully, but it does not follow that this holds in nature. But this is the subject of another research" (GM III 516). Accidental impossibility of Leibniz's infinitesimals has been argued in Esquisabel and Raffo Quintana (2021).

[21] The rules are discussed in the *Nova Methodus pro maximis et minimis*, published in 1684 in the *Acta Eruditorum* [GM V pp. 220–226].

imaginary numbers, in his mature philosophy, Leibniz refers to infinitesimals using the language of imagination – to feign, fictions – and contrasts them with more traditional mathematical notions, referred to as ideal concepts, which are the image, although idealized, of physical situations.[22]

3.2 Five Phases

As mentioned above, Leibniz reached this final position through a complex path, which we will trace in the present section. We have focused our attention on five phases, which are especially significant for reconstructing the entire evolution. Except for phase I, where Leibniz's physical and mathematical analysis do coincide, we have treated them separately, as far as possible.

3.2.1 Phase I (1668–1669)

While in his mature philosophy Leibniz will analyze physical bodies in terms of individual metaphysical substances, he was initially confident that one should banish from physics any metaphysical explanations and replace them by purely mechanical ones. In particular, Leibniz attempted to reduce the Aristotelian triad *matter-form-change*,[23] which he considered too abstract, to the "mechanical" triad *extension-shape-motion*. Wrote Leibniz:

> The one question is whether Aristotle's abstract theories of matter, form, and change can be explained by magnitude, shape, and motion. This the Scholastics deny and the philosophical reformers affirm. The latter opinion seems to me to be not only the more true but also the more consistent with Aristotle. [*Leibniz to Thomasius*, April 1669. A2.1[2]. 25–26. Transl. Loemker with minor changes][24]

A physical body is the compound of a passive element, or matter, which Leibniz identifies with extension,[25] and an active one, or form, which he identifies with shape. Both extension and shape are dealt with in a rather simplistic way, in accordance with the fact that in this phase, Leibniz's knowledge of mathematics, which essentially means Greek geometry, is rather basic, and for the most part acquired by reading philosophical works. In particular, extension is continuous,

[22] On Leibniz's ideal notions, see Sherry and Katz (2014) and Katz and Sherry (2013).

[23] The noun *change* is our rendering of Aristotle's μεταβολή, which includes motion (κίνησις, namely local change) as well as qualitative and quantitative changes.

[24] "Hoc unum in quaestione est, an quae Aristoteles de materia, forma, et mutatione abstracte disputaverit, ea explicanda sint per magnitudinem, figuram, et motum. Id Scholastici negant, Reformatores affirmant. Reformatorum sententia mihi non solum verior, sed et Aristoteli magis consentanea videtur." Here and throughout the chapter, we have rendered "figura" with "shape," instead of Loemker's "figure."

[25] In physical bodies, extension is coupled with impenetrability, which sometimes Leibniz prefers to call antitypy (ἀντιτυπία): "To be extended, however, is nothing else but to be in space, and antitypy is the impossibility of being in the same space with another thing" [*Leibniz to Thomasius*, April 1669. A2.1[2]. 36. Transl. Loemker].

and continuity means for Leibniz potentially infinite divisibility, that is syncategorematicity, as it was for Aristotle.[26] The terminology itself of unassignability and infinitesimals is absent in this phase: "infinitely small" just means "potentially infinitely divisible."[27]

> Matter has quantity too, though it is indefinite, or interminate as the Averroists call it. For being continuous, it is not cut into parts and therefore does not actually have boundaries. [*Leibniz to Thomasius*, April 1669. A2.1[2]. 26–27. Transl. Loemker][28]
>
> Space is a primary extended being or a mathematical body, which contains nothing but three dimensions and is the universal locus of all things. Matter is a secondary extended being, or that which has, in addition to extension or mathematical body, also a physical body, that is, resistance, antitypy, solidity, the property of filling space, impenetrability[29] [*Leibniz to Thomasius*, April 1669. A2.1[2]. 34. Transl. Loemker with minor changes][30]

Motion intervenes in the generation of physical bodies. In particular, it is responsible for their shape:

> Form (in the technical sense) as educed from the potentiality of matter, is nothing more than this particular shape of the whole as generated from this particular motion of matter, and from this particular situation of parts: e.g., the form of a square ⊡ *c* is educed from the union of two triangles, Δ *a* and ∇*b*, and from the potentiality of their matter to be in reciprocal contact by motion. [*Leibniz to Thomasius*, October 1668. A2.1[2].17][31]

[26] Aristotle characterizes the continuum as "infinitely divisible" (*Physics* III 1, 200b18; I 2, 185b10–11; VI 6, 237a33; VI 8, 239a22) or "divisible into what is always (*aei*) divisible" (*Physics* VI 2, 232b24–25; see IV 12, 220a30; VI 1, 231b15–16; VI 6, 237b21; VIII 5, 257a33–34; *On the heavens* I 1, 268a6–7). Infinite divisibility is an essential property of the *continuum*, which directly follows from Aristotle's definition of continuity, as a relational notion: two parts of a whole are said to be continuous with one another when they are in contact and their ends therefore become one (συνεχῆ μὲν ὦντὰ ἔσχατα ἕν *Physics* VI 1, 231a21–22 "we defined continuous things whose ends are one"); see also *Physics* V 4, 228a29–30; V 3, 227a11–12; *Cat.* 6, 4b20–5a14. We discussed the continuum as always (*aei*) divisible in Sect. 2.2.

[27] Cf. the analysis of the infinitely small in *Physics* III.6, where Aristotle argues against the existence of indivisible lines (ἀτόμους γραμμάς 206a17–18).

[28] "Quantitatem quoque habet materia, sed interminatam, ut vocant Averroistae, seu indefinitam, dum enim continua est, in partes secta non est, ergo nec termini in ea actu dantur."

[29] Resistance, antitypy, solidity, the property of filling space, and impenetrability are synonyms and refer to the impossibility, for a physical body, of being in the same space with another thing, as Leibniz explains a few lines later.

[30] "Spatium est Ens primo-extensum, seu corpus mathematicum, quod scilicet nihil aliud continet quam tres dimensiones, estque locus ille universalis omnium rerum. Materia est ens secundo-extensum, seu quod praeter extensionem vel corpus mathematicum habet et corpus physicum, id est, resistentiam, ἀντιτυπίαν, crassitiem, spatii-repletivitatem, impenetrabilitatem."

[31] "Formam enim educi ex potentia materiae, nihil aliud est, quam ex hoc materiae motu, ex hoc partium situ, hanc totius figuram oriri: v.g. ex unione duorum triangulorum, Δ *a* et ∇*b*, et ex potentia materiae eorum ad contactum mutuum per motum, educitur forma quadrati ⊡ *c.*" In this case, the resulting square does not keep trace of the way in which it has been created. The same example of the square arising from two triangles appears in a 1676 note – see footnote 71 – but here Leibniz resorts to metaphysics in order to obtain a form which keeps trace of its constituents.

The world is a plenum, made of continuous bodies, actually divided from each other:

> This makes it clear that, if mass were created discontinuous or separated by emptiness in the beginning, there would at once be certain concrete forms of matter. But, if it is continuous in the beginning, forms must necessarily arise through motion. For division comes from motion, the bounding of parts comes from division, their shapes come from this bounding, and forms from shapes; therefore, forms come from motion [. . .] From this it is clear that every arrangement into a form is motion, and the vexatus problem of the origin of forms is answered.[32] [*Leibniz to Thomasius*, April 1669 A2.1[2].26–27. Transl. Loemker][33]

Phase I in Summary

Physics: physical objects are continuous; continuous = in(de)finitely divisible; parts are only potential and finite. Both the approach and the terminology employed are syncategorematic.

Mathematics: mathematical objects are continuous; continuous = in(de)finitely divisible; parts are only potential and finite. Both the approach and the terminology employed are syncategorematic.

3.2.2 Phase II (1670–1671)

Continuity as conceived by Aristotle, and as employed by Leibniz in phase I, means potentiality of the parts, and potentiality means indefiniteness. However, indefiniteness, in Leibniz's opinion, has more to do with Descartes' thoughts that with reality; see item (2) below. Phase II represents Leibniz's first attempt to overcome this difficulty without abandoning his initial purpose of leaving aside any metaphysics. However, Leibniz's poor knowledge of mathematics will prove to be a hindrance to effective implementation of the project.[34]

Phase II in Physics

The project was to give some sort of individuality to the parts of a physical body, still treating them as continuous. For doing so, Leibniz broadens the notion of continuity

[32] As Leibniz himself wrote some years later: "Tempus erat quo credebam, omnia Motuum Phaenomena principiis pure Geometricis explicari posse, nulli Metaphysicis propositionibus assumptis" [There was a time when I believed that all the phenomena of motion could be explained on purely geometrical principles, assuming no metaphysical propositions. *Principia mechanica ex metaphysicis dependere* 1678/81 A6.4.1976, Transl. Ariew-Garber].

[33] "Ex his patet siquidem ab initio massa discontinua seu vacuitatibus interrupta creata sit, formas aliquas statim materiae concreatas esse; sin vero ab initio continua est, necesse est, ut formae oriantur per motum (nam de annihilatione certarum partium ad vacuitates in materia procurandas, quia supra naturam est, non loquor) quia a motu divisio, a divisione termini partium, a terminis partium figurae earum, a figura formae, ergo a motu formae. Ex quo patet, omnem dispositionem ad formam esse motum, patet quoque solutio vexatae de origine formarum controversiae."

[34] On Leibniz's knowledge of mathematics before his stay in Paris, see, for instance, Hofmann (1974), pp. 1–11.

and affirms – without any concern for the mathematical consistency of the statement – that a continuous body is not merely infinitely divisible, but it is infinitely divided into parts, and these parts are actual:

> (1) *There are actually parts in the continuum*
> (2) *these are actually infinite*, for Descartes's indefinite is not in the thing but in the thinker [*Theoria motus abstracti* 1671, A6.2. 264. Transl. Arthur][35]

Being actual, the parts of a physical body are organized in a precise way. Therefore, in this phase, form does not depend only on the external shape of the body, as in phase I, but also on the disposition of its internal parts:

> For Aristotle too, substantial form (with the exception of mind) is not an absolute entity, but only a *logos*, a ratio, a proportion, a number, a structure of internal parts. [*Hypothesis Phisica Nova* 1671. A6.2. 247][36]

But how can these parts stay together, forming a continuous body? To solve the problem, Leibniz resorts to motion: being in motion, parts experience an endeavor (*conatus*)[37] to penetrate each other, and this causes their extremities to become one. But the coincidence of the extremities of the parts is the condition Aristotle requires in order to have a continuous, unitary whole (see note 27):

> I should think that the *conatus* of the parts toward each other, or the motion through which they press upon each other, would itself suffice to explain the cohesion of bodies. For bodies which press upon each other are in a *conatus* to penetrate each other. The *conatus* is the

[35] "Dantur actu partes in continuo [. . .] eaeque infinitae actu, indefinitum enim Cartesii non in re est, sed in cogitante." We find the same assumption in Leibniz's *Hypothesis Phisica Nova*, dated shortly before and also known as *Theory of concrete motion*: "Quae res ob divisibilitatem cujuslibet continui in partes quantumvis parvas in infinitum non est difficilis explicatu" [*Hypothesis Phisica Nova* 1671. A6.2 224]. Here physical bodies are thought as made of parts, or *bullae* (bubbles), in a more or less solid state, depending on the circumstances: "Principio autem ex fluidi aestuatione et fusione per lucem seu calorem ortae sunt bullae innumerabiles ac magnitudine crassitieque variantes. Nam quoties subtilia perrumpere per densa conantur, et est quod obsistat, formantur densa in cavas quasdam bullas, motumque partium internum, ac proinde consistentiam seu cohaesionem (per nostram *de motu Theoriam*, theor. 17) nanciscuntur." [*Hypothesis Phisica Nova* 1671. A6.2 226].

[36] "Certe formas substantiales (demta mente) etiam Aristoteli non esse ens absolutum, sed tantum λόγον, rationem, proportionem, ἀριθμόν, structuram partium intimam."

[37] Leibniz borrows the notion of *conatus* from Hobbes' endeavor, which has a very similar definition, and a very similar role in physics. However, while Leibniz's *conatus* are unextended, Hobbes' endeavors are finite quantities, although negligible, like his points: "I define endeavour to be Motion made in less Space and Time then can be given; that is, less than can be determined or assigned by Exposition or Number; that is, Motion made through the length of a Point, and in an Instant or Point of Time" [*De Corpore* 3.15.2]. For Hobbes, a point is not "that which has no quantity" but "that whose quantity is not at all considered" [ibid.]. On the role of Hobbes as the mediator between the young Leibniz and mathematics, and particularly Cavalieri's method, see, for instance, Hofmann (1974).

> beginning (*initio*); the penetration is the union. But when bodies begin to unite, their beginnings or extremities (*termini*), are one. Bodies whose extremities are one, or τὰ ἔσχατα ἕν, are according to Aristotle's definition not only contiguous but continuous, and truly one body, movable in one motion [*Leibniz to Hobbes*, July 1670. A2.1[2]. 92. Transl. Loemker with minor changes][38]
>
> If one body strives against another, this is the beginning of mutual penetration or union or that the boundaries of the two are one, as Aristotle defines a continuum [*Leibniz to Arnauld*, November 1671. A2.1[2]. 279. Transl. Loemker][39]

In his more applied writings, Leibniz describes this situation in concrete terms. The behavior of the parts of physical bodies, which he calls "bubbles," is explained in analogy with what happens in a turbulent fluid: as the bubbles which are continuously produced and destroyed in a fluid, also the parts of a body are elastic and constantly move, breaking and recombining with each other.

Phase II in Mathematics

As in phase I, Leibniz does not draw a clear distinction between physics and its mathematical description, but while in phase I continuity as potentially infinite divisibility had a clear meaning both in physics and in mathematics – a body is made of continuous parts in the same way as a segment is made of segments – the composition of bodies as conceived by Leibniz in phase II is more difficult to translate in mathematical terms.

The main problem is the mathematical *status* of the actually infinite parts and their relationship with unassignable endeavors.

Later in the *Theory of abstract motion*, we learn that Leibniz rejects *minima* (i.e., points as constituent parts of the continuum in the modern sense) and *maxima*, where a maximum is an unbounded infinite line (the kind we have in modern Euclidean geometry). The reason for both is a violation of the part-whole principle that would ensue via Galileo's paradox:

> (3) *There is no minimum in space or body*, that is, nothing which has no magnitude or part. For such a thing has no situation, since whatever is situated somewhere can be touched by several things simultaneously that are not touching each other, and would thus have several faces; nor can a minimum be supposed without it following that the whole has as many minima as the part, which implies a contradiction. [*Theoria motus abstracti* 1671, A6.2. 264. Transl. Arthur][40]

[38] "Ego crediderim ad cohaesionem corporum efficiendam sufficere partium conatum ad se invicem, seu motum quo una aliam premit. Quia quae se premunt sunt in conatu penetrationis. Conatus est initium, penetratio unio. Sunt ergo in initio unionis. Quae autem sunt in initio unionis, eorum initia vel termini sunt unum. Quorum Termini sunt unum seu τὰἔσχαταἕν, ea etiam Aristotele definitore non jam contigua tantum, sed continua sunt, et vere unum corpus, uno motu mobile."

[39] "Si corpus conetur in corpus, esse ambo in initio penetrationis seu unionis, seu extrema eorum unum esse ut continuum definit Aristoteles [ὦν] τὰ ἔσχατα ἕν."

[40] "Nullum est minimum in spatio aut corpore, seu cujus magnitudo vel pars sit nulla: talis enim rei nec situs ullus est, cum quicquid alicubi situm est, simul a pluribus se non tangentibus tangi possit, ac proinde plures habeat facies; sed nec poni Minimum potest, quin sequatur tot esse totius, quot partis minima, quod implicat."

On the other hand, he acknowledges the existence of indivisibles – namely the mathematical counterpart of endeavors – and argues as follows:

> (4) *There are indivisibles or unextended things*, otherwise neither the beginning nor the end of a motion or of a body is intelligible. This is the demonstration: any space, body, motion, and time has a beginning and an end. Let that whose beginning is sought be represented by the line *ab*, whose midpoint is *c*, and let the midpoint of *ac* be *d*, that of *ad* be *e*, and so on. Let the beginning be sought to the left, on *a*'s side. I say that *ac* is not the beginning, since *dc* can be taken away from it without destroying the beginning; nor is *ad*, since ed can be taken away, and so on. Therefore, nothing is a beginning from which something on the right can be taken away. But that from which nothing having extension can be taken away is unextended. Therefore, the beginning of a body, space, motion, or time (namely, a point, an endeavour, or an instant) is either nothing, which is absurd, or is unextended, which was to be demonstrated [*Theoria motus abstracti* A6.2. 264. Transl. Arthur with minor changes][41]

Endeavors are unextended amounts of motion, and indivisibles, or "fat points" (our term) are unextended portions of bounded lines.

Moreover, unlike Euclidean or Aristotelian points, which are "unextended beginnings" of lines but do not enter in their composition, Leibnizian "fat points" do make lines (and "fat lines" do make surfaces. . .).

As a consequence, even if they are smaller than any assignable quantity, "fat points" can be compared with each other. In Leibniz's words, they are different in "magnitude": bigger in a bigger curve, smaller in a smaller one:

> The cone is made by as many circles parallel to the basis as points of the height [*Nugae pueriles* 1670. A7.4. 57–58][42]
>
> Whence the unassignable arc of a bigger circle is greater than that of a smaller one [*Theoria motus abstracti* A6.2. 267. Transl. Arthur][43]
>
> An *arc* smaller than any that can be given is still greater than its chord, although this is also smaller than can be expressed, i.e., consists in a point. But that being so, you will say, an *infinitangular polygon* will not be equal to a circle: I reply, it is not of an equal magnitude, even if it be of an equal extension: for the difference is smaller than can be expressed by any number [*Theoria motus abstracti* A6.2. 267. Transl. Arthur][44]

[41] "Dantur indivisibilia seu inextensa, alioquin nec initium nec finis motus cor porisve intelligi potest. Demonstratio haec est: datur initium finisque spatii, corporis, motus, temporis alicujus: esto illud cujus initium quaeritur, expositum linea *ab,* cujus punctum medium *c,* et medium inter a et c sit *d,* et inter *a* et *d* sit *e,* et ita porro: quaeratur initium sinistrorsum, in latere a. Ajo ac non esse initium quia ei adimi potest *dc* salvo initio; nec *ad,* quia *ed* adimi potest, et ita porro; nihil ergo initium est, cui aliquid dextrorsum adimi potest. Cui nihil extensionis adimi potest, inextensum est; initium ergo corporis, spatii, motus, temporis (punctum nimirum, conatus, instans) aut nullum, quod absurdum, aut inextensum est, quod erat demonstrandum." Note that from the same premises, and with a similar proof, Aristotle reached the opposite conclusion: a motion has neither a beginning nor an end (Physics VI.5; cf. VI 1 where Aristotle's proves the impossibility of indivisibles).

[42] "Constabit conus ex tot circulis basis parallelis quot sunt puncta altitudinis."

[43] "Unde arcus inassignabilis circuli majoris major est quam minoris"

[44] "Arcus minor quam qui dari potest, utique chorda sua major est, quanquam haec quoque sit minor quam quae exponi potest, seu consistat in puncto. At ita, inquies, Polygonum infinitangulum non erit circulo aequale: respondeo, non esse aequalis magnitudinis, etsi sit aequalis extensionis: differentia enim minor est quam ut ullo numero exprimi possit"

> A point can be bigger than another, but in a smaller ratio (*in ratione minore*), than the one that can be exhibited, or infinite with respect to any sensible quantity [*Leibniz to Arnauld*, November 1671. A2.1[2]. 278][45]

The main problem with this picture is the necessity of distinguishing between "having extension" and "having magnitude," a problem that Leibniz thinks he has solved by employing the locution "having magnitude" as synonymous with "having parts," where parts are not necessarily "external to each other." In fact, Leibniz says, parts can be indistant, and this is the basis of Cavalieri's method too:

> (5) *point is not that which has no part*, nor that whose part is not considered; but that which *has no extension*, i.e., whose parts are indistant, whose magnitude is inconsiderable, unassignable, is smaller than can be expressed by a ratio to another sensible magnitude unless the ratio is infinite, smaller than any ratio that can be given. But this is the basis of the *Cavalierian Method*, whereby its truth is evidently demonstrated, inasmuch as one considers certain rudiments, so to speak, or beginnings, of lines and figures smaller than any that can be given. [*Theoria motus abstracti* A6.2. 265. Transl. Arthur][46]
>
> The nature of points is undeniably admirable: indeed, although a point is not divisible into parts external to each other, however it is divisible into parts which before were not external to each other, or into parts that before were penetrating each other. [*Leibniz to Oldenbourgh*, September 1670. A2.1[2]. 103][47]

Summarizing, Leibniz tries to reconcile the actuality of the infinite parts into which physical bodies are divided – and not only divisible – and the potentiality of matter. As material parts, in fact, their magnitude can decrease ad infinitum (no *minima*).[48]

But the conflation between actuality and potentiality is not the only flaw in Leibniz's construction. Furthermore, the physical notion of *conatus*, that is of an endeavor of motion, creates problems when one tries to translate it into mathematics.

Two physical endeavors can have the same extension (in fact, they have no extension) but a different "intension": for instance, when one begins a faster motion

[45] "Esse punctum puncto majus, sed in ratione minore, quam quae exponi potest, seu ad sensibilem quamcumque infinita."

[46] "Punctum non est, cujus pars nulla est, nec cujus pars non consideratur; sed cujus extensio nulla est, seu cujus partes sunt indistantes, cujus magnitudo est inconsiderabilis, inassignabilis, minor quam quae ratione, nisi infinita, ad aliam sensibilem exponi possit, minor quam quae dari potest: atque hoc est fundamentum Methodi Cavalierianae, quo ejus veritas evidenter demonstratur, ut cogitentur quaedam ut sic dicam rudimenta seu initia linearum figurarumque qualibet dabili minora"

[47] "Admirabilis profecto est natura punctorum; quanquam enim punctum non sit divisibile in partes positas extra partes, est tamen divisibile in partes antea non positas extra partes, seu in partes antea se penetrantes"

[48] A different interpretation has been propounded in Arthur (2009, pp. 17–18), which identifies actually infinite parts with points: in this case, the whole physical construction could be traced back to Cavalieri's theory, and Leibniz's construction would appear more consistent. In principle, this would be an appealing interpretation, the only problem being that there is no basis for it in Leibniz's text. In particular, he never identifies the physical notions of part and point, and repeatedly refers to points as extremities of parts.

than the other. But what does it mean that two unextended "fat points" do have a different "magnitude"? Leibniz's explanation in term of indistant inner parts, which can penetrate each other, does not have a clear meaning in mathematics. However, this analysis is never elaborated by Leibniz, who merely claims that with the identification of his "fat points" with indivisibles he has demonstrated Cavalieri's method, too.[49]

Phase II in Summary

Physics: physical objects are actually infinitely divided into continuous material parts (no *minima*) whose extremities coincide. Extremities are held together by unextended endeavors of motion.

Mathematics: material extension is represented by a continuum, as in phase I. Endeavors of motion are represented by unextended "fat points," unassignable and indivisible, which have parts but parts that are indistant.

3.2.3 Phase III (1672–1674)

Phase III, which coincides with the first years of Leibniz's stay in Paris, marks the beginning of his mathematical career. It is in Paris that Leibniz undertakes serious training in mathematics and enters in relation with Huygens, and then with other leading mathematicians, who will become his correspondents.

In phase II, Leibniz's knowledge of the contemporary methods for solving the problems related to infinity was rather poor. He realized the importance of Cavalieri's indivisibles, and more generally of unassignable infinitely small quantities, but he lacked the technical tools necessary in order to transform a philosophical intuition into a mathematical investigation.

The idea of a point with indistant parts, for instance, while appealing and maybe effective in a dialectical argument, was very hard to disambiguate and to translate into a sound mathematical notion. Analogously, the coexistence of actuality and potentiality implied in Leibniz's analysis of physical bodies would lead to serious problems, if mathematically analyzed.

But in phase II, Leibniz did not seem aware of the existence of such difficulties, which become clear only in subsequent years, as his mathematical knowledge grew. For this reason, even if in terms of effective results phase III is merely a transitional phase, it is a crucial step in our analysis. Even though Leibniz did not publish anything, the large amount of handwritten notes he left, often inconclusive and vitiated by inconsistencies, show nevertheless the awareness of the impasse which phase II was leading to, and the attempt to avoid it.

[49] On the ambiguous relation between indivisibles and motion, see Cavalieri's reaction to Guldin's critique (*Exercitationes geometricae sex*, Exercitatio III, cap. VII). Cf. Cavalieri (1966) tr. Radice 808–810.

Phase III in Physics

The first novelty, which Leibniz introduces in physics in order to keep actuality and potentiality separate, consists in reversing the arrow of the analysis: if, by dividing a continuum, one can only reach potentially divisible parts, the only way to obtain a matter made of genuine actual ultimate parts is to start from these parts.

Both in phases I and II, the basic stuff – from which physical bodies was derived – was a continuous entity: once continuity was broken, in virtue of motions, parts were created, which entered into the composition of physical bodies. In phase III, by contrast, the ultimate element is a plurality of basic material entities, discrete from the outset, spherical, which aggregate in order to give rise to physical bodies. Leibniz calls them "atoms" or *bullae*, or *terrellae*:

> Sensible bodies are aggregates of countless (innumerabilium) terrellas [*Propositiones quaedam physicae*, 1672. A6.3.32][50]

By introducing discrete elements, which have a proper individuality and self-sufficiency, Leibniz solves any ambiguity concerning their *status*: the ultimate parts are actual and indivisible.

The problem is that these atoms are meant to be part of bodies which are continuous: how is this possible? Leibniz solves the problem in one direction, showing how a continuous stuff can be obtained starting from discrete elements. As in phase II, in fact, he resorts to motion for welding together the material atoms which form a body: due to their endeavors to motion, the discontinuities between different atoms disappear:

> If a body is forced (*conetur*) into the place of another, these two bodies are continuous [*De consistentia corporum* 1672/3. A6.3.95][51]

Moreover, due to their smallness, even the empty spaces which exist between the spherical atoms become negligible and do not interrupt continuity:

> It is necessary that matter is uninterrupted, and it completely fills the space, or at least it leaves some unnoticeable (*insensibiles*) empty islands, without any breaking of continuity. [*Demonstratio substantiarum incorporearum*, 1672. A6.3. 78][52]

[50] "Corpora sensibilia sunt aggregata innumerabilium terrellarum." A *terrella* is a little spherical loadstone, as described in Gilbert, *De Magnete* 1600.

[51] "Si corpus unum conetur in alterius locum, ea duo corpora continua sunt."

[52] Leibniz will come back on the status of *vacua intermixta*, which he calls also *vacua metaphysica* and their incomparable magnitude some years later, in phase IV: "[. . .] because spheres, however many they may be, do not fill a whole. However, all emptinesses collected into one have no greater ratio to any assignable space than the angle of contact has to a straight line" [*De summa rerum* 1675/6. A6.3. 526. Transl. Parkinson]. "A metaphysical vacuum is an empty place, no matter how small, provided that it is genuine and real. A physical plenum is consistent with a metaphysical vacuum which is unassignable" [*De summa rerum* 1675/6. A6.3. 473. Transl. Parkinson]. Note that in this period and in this context, the term "metaphysical" still retains a negative connotation, keeping track of the "empty words" imputed to scholasticism.

But once physical bodies are continuous, they must be also infinitely divisible:

> This sounds paradoxical – I must admit – but is no less necessary than the actual division of the continuum, in infinite parts (which follow from this exact proof, consistently with Cartesian teachings) and other marvels of the internal nature [*Propositiones quaedam physicae*, 1672. A6.3.57][53]

And then the question arises, how can individuality and infinite divisibility coexist?

Reading Leibniz's notes, it seems that the only possible answer is that they cannot, and that the only way to obtain a consistent description of physical bodies is to eliminate any (atom of) matter:

> From this we understand that matter and motion, or *conatus*, are the same [. . .] And getting back to our issue, it is clear from these facts that matter does not consist of extension, but of motion, and a lot of matter is nothing more than a lot of motion. [*Propositiones quaedam physicae*, 1672. A6.3 56][54]
>
> Hence it follows that there is no matter in body distinct from motion, since it would necessarily contain indivisibles. [*De minimo et maximo* 1672/3. A6.3. 100][55]

In other words, motion can contain indivisibles, matter cannot. And here two difficulties arise: is a motion made of unassignable indivisibles continuous? And if it is, in what sense? Moreover, if bodies are nothing but motion, what happened to the atoms of matter? Leibniz's writings of this period do not contain an answer, and in fact, even if the starting point was different, the physical theory of continuity Leibniz builds in phase III ends up with the same inconsistencies as the one he built in phase II.

Phase III in Mathematics

In mathematics, the situation is less problematic, although some doubt remains concerning the composition of the continuum. Apparently, Leibniz's mathematical continua can be read as entirely composed of "fat points," since now these points are no longer seen as unextended, but as extended infinitely small lines. As their ancestors, these new points are unassignable, i.e., infinitely smaller than any assignable line:

> Continuous space is made of parts smaller than anything determinable by us [*Demonstratio substantiarum incorporearum*, 1672. A6.3.81]

---

[53] "Res est fateor paradoxa sed non minus necessaria, quam divisio continui actualis, in partes infinitas (quae ex hac ipsa demonstratione confessione Cartesii sequitur) aliaque naturae interioris admiranda"

[54] "Unde intelligi potest, materiam et motum vel conatum idem esse [. . .]. Patet ergo ex his, ut viam redeam, materiam non consistere in extensione, sed in motu, et nihil aliud esse mulatm materiam, quam multum motum."

[55] "Hinc sequitur nullam esse in corpore materiam a motu distinctam, ea enim necessario indivisibilia contineret."

> In a continuum there are some infinitely small things, or infinitely smaller than any perceptible one [*De minimo et maximo* 1672/3. A6.3.98].
>
> A point can be infinitely smaller than another [*De minimo et maximo* 1672/3. A6.3.99][56]

In this period "infinitely small," "unassignable" and "point" are employed as synonyms:

> In short: each of these scalene triangles is a point, because their base and height are infinitely small lines. For this reason, all together, arranged on a single straight line obtained from the extended evolute (in fact, the triangles are as many as the points of the chord) do not make but a line [*Varia de cycloeide* 1673 A7.4 p. 74][57]

Here indivisibles are defined as synonymous with infinitely small:

> Indivisibles are to be defined as infinitely small, or as having infinite ratio, or difference, with a sensible quantity [A7.4 p. 265][58]

During these years, the term "infinitesimal" makes its appearance, but it is always employed in the phrase "infinitesimal (part) of" and denotes a particular case of infinitely small line: the infinitesimal part of a quantity is one of the infinitely many equal parts into which the quantity has been divided[59]:

> We suppose that the abscissa AE is divided into equal infinitely many equal parts as EF, FG [. . .] And the straight line EF, or FG will be infinitely small, and each one will be an infinitesimal of the abscissa AE [*Methodus nova investigandi tangentes linearum curvarum*. . . 1673 A7.4 p. 657][60]
>
> And this is the proof: suppose that MNE is the characteristic triangle of the figure, that is the one whose height MN is an infinitesimal of the height of the figure [*Trigonometria inassignabilium* 1673 A7.4 p. 497][61]

[56] "Spatium Continuum componitur ex partibus qualibet a nobis determinabili minoribus." "Sunt aliqua in continuo infinite parva, seu infinities minora, quovis sensibili dato." "Punctum unum alio potest esse infinities minus."

[57] "Idem brevius: quodlibet ex his triangulis scalenis punctum est, cum eius basis et altitudo sint lineae infinite parvae. Ergo omnia simul, in unam rectam ex evoluta extensa conflatam disposita (tot enim sunt scalena, quot in ea chordae, seu puncta) non nisi lineam facient." Note that not only infinitely small lines are called points but also infinitely small figures (cf. in particular *Plagula* 16_4 A7.4 pp. 304–331).

[58] "*Indivisibilia* definienda sunt infinite parva, seu quorum ratio ad quantitatem sensibilem (vel differentia) infinita est."

[59] It is interesting to note that a similar position, namely the idea that one can reach infinitesimals at an infinitieth stage of getting smaller and smaller, will be maintained by Bernoulli, and repeatedly criticized by the mature Leibniz, in their 1698 correspondence (GM III 529–554, see in particular pp. 539, 541 and 551).

[60] "Intelligatur abscissa AE dividi in partes aequales infinitas, quales sunt EF. FG. [. . .] Eritque recta EF. vel GH. infinite parva, eademque erit infinitesima rectae AE. abscissae."

[61] "Demonstratio haec est: intelligatur triangulum figurae characteristicum esse MNE. cuius scilicet altitudo MN est infinitesima altitudinis figurae." Cf. A7.4 p. 432; 493; 494; 497; 663.

Infinitesimals are often employed as "unities":

> And we suppose EE infinitesimal, that is the unity for the construction = 1 [*Varia circa functiones*... 1673 A7.4 p. 755][62]
>
> I'll grant you that, but I maintain that this 1 must be denoted in this way 1r. In fact it is not 1, or a certain number, but is something indivisible, which in this construction works as unit, that is to say the infinitesimal part of a certain line, divided in thought into infinite equal parts [*De paraboloeidum et hyperboloeidum quadratura II* 1673 A7.4 p. 607][63]

As in phase II, the notion of unassignable quantities does not seem particularly to worry Leibniz, but the new writings bear witness to a deepening in his analysis. On one hand, the vague notion of indistant parts disappears; on the other hand, we encounter the first mentions of imagination: a curve is divided "in thought" (*cogitatione*) into infinitesimal pieces.

Moreover, a hiatus is being created between what we perceive in physics, namely a continuous matter, made of assignable parts, and what is behind the appearance, that is motion and its unassignable *conatus*. The apparent and the deeper level seems to have two different mathematical counterparts.

3.2.4 Phase IV (1675–1676)

In phase IV, we witness the reemergence of metaphysical explanations, which Leibniz had strongly criticized in phase I, but with a new awareness, for now metaphysics does not supplant mathematics, but will complement it. The idea is that mathematics provides a description of natural phenomena, which although approximate and idealized makes physical problems manageable and as predictable as possible. But mathematics does not give the true laws of physics, which are instead provided by metaphysics. As Leibniz recalls decades later:

> Mais quand je cherchay les derniers raisons du Mechanisme et les loix mêmes du mouvement, je fus tout surpris de voir qu'il etoit impossible de les trouver dans les Mathematiques, et qu'il falloit retourner à la Metaphysique. C'est ce qui me ramena aux Entelechies, et du materiel au formel. [*Leibniz to Remond*, 1714. GIII 606][64]

Phase IV in Physics

Concerning the problem of the composition of physical bodies, Leibniz resorts to metaphysics in order to get the actuality he needs. Although physical bodies are infinitely divisible – namely they are capable of all resolutions into parts – the

[62] "Et posita EE infinitesima seu unitate constructionis = 1."

[63] "Ego fateor, sed aio illud 1 notandum esse hoc modo 1r. neque enim esse 1, seu numerum illum, sed esse indivisibile aliquod, quod in praesenti constructione unitatis personam sustinet, sive quod est infinitesima pars lineae cuiusdam, in partes aequales infinitas cogitatione divisae."

[64] "But when I looked for the ultimate reasons for mechanism, and even for the laws of motion, I was greatly surprised to see that they could not be found in mathematics but that I should have to return to metaphysics. This led me back to entelechies, and from the material to the formal" [Transl. Loemker].

potentiality of these parts is overcome by attributing to parts not only a motion but a soul, or mind[65]:

> And so one must examine rigorously whether there follows the perfect division of a liquid into metaphysical points, or only into mathematical points. For mathematical points could be called *indivisibiles* of Cavalieri, even if they are not metaphysical, i.e., are not minima. But if it could be shown that a liquid is divided to a greater or lesser extent, it would follow that a liquid is not resolved in[to] indivisibiles. But one could defend the composition of a liquid out of perfect points, even if it is never wholly resolved into them, since it is capable of all resolutions, and will cease when its cement – namely, mind and motion – ceases. [*De Summa Rerum* 1676. A6.3. 474. Transl. Parkinson][66]
>
> And a single indivisible body – or ἄτομον – arises, of whatever magnitude, every time it has a soul. [*Metaphysical notes* 1676. A6.3. 393]

In this way, the material parts of a physical body can be said to be unities in a proper sense – namely indivisible actual wholes – and simultaneously infinite.

The situation is apparently similar to the one described in phases II and III: we have an infinitely divided material stuff, and "something" that keeps the parts together. The crucial difference is that while in phases II and III both the material parts and the "cement," that is their *conatus* of motion, were physical entities, in phase IV, the bond is not physical but metaphysical, due to the fact that parts have minds, or souls.

So, while in phase III a geometrical representation of both the infinitely divisible assignable parts and their unassignable *conatus* was needed, because both belonged to physics, in phase IV, a geometrical description is needed only for the infinitely divisible physical parts. As metaphysical notions, indeed, minds reside on another level.

In particular, they can be conceived as unassignable and unextended without any need to resort to a definition of "magnitude" different from "extension." In phase IV, in fact, being unextended is something more than a quantitative property: minds are unextended, because as any metaphysical entity, they are extraneous to the category of extension, and more generally to the category of quantity. As such, they are also unassignable.

[65] In this period, Leibniz uses the Latin "mens" (mind) to mean every kind of mind-like substances. In later writings, he distinguishes between minds (*mentes*), souls (*animae*), and "bare" monads. Monads are capable of perceptions; souls are capable of perception and consciousness; minds are capable of rational perceptions and self-consciousness.

[66] "Adeoque examinandum rigorose, an perfecta divisio liquidi in puncta metaphysica, an vero tantum in puncta mathematica sequatur. Nam puncta mathematica possent appellari indivisibilia Cavaleriana, etsi non sint metaphysica seu minima. Quod si ostendi posset plus minusve dividi liquidum, sequetur non resolvi liquidum in indivisibilia. Posset tamen defendi liquidum componi ex punctis perfectis, etsi nunquam in illa prorsus resolvatur, vel ideo quia omnium est resolutionum capax, et caemento cessante, mente scilicet et motu, cessabit."

If at the very beginning the separation between minds and their expression is not so clear,[67] as Leibniz himself admits in later writings, in his mature theory, any conflation of metaphysical and material elements of a body disappears:

> Many years ago, when my philosophy was not yet sufficiently mature, I located souls in points [. . .] But after further reflection, I discovered that in this way we are not only led into innumerable difficulties, but that there is also here a certain, as it were, category mistake (μετάβασιν εἰς ἄλλο γένος). Those things that pertain to extension should not be attributed to souls, and their unity and multitude should not be taken from the category of quantity, but rather from the category of substance.[68] [*Leibniz to Des Bosses* April 30 1709; G II, 372. Transl. Look-Rutherford. See Leibniz (2007)]

Leibniz's reference to a category mistake is significant, because it points at the very heart of the problem: the conflation of substantial and quantitative analysis of physical bodies.

As we mentioned, in phase I, Leibniz thought that he could avoid any difficulty of this kind by banishing metaphysics from physics: no substantial immaterial forms are needed to define physical objects, which are completely identified by their geometrical shape, and mechanical implications.[69] Physical objects are continuous, divisible into potentially infinite assignable extended parts, where the adjective *infinite* is taken in its quantitative meaning.

The main problem with this geometric/mechanical interpretation was the indefiniteness of the parts into which bodies can be analyzed, but of which they cannot be "made," at least in a proper sense. In phases II and III, Leibniz tried to solve the problem by hypothesizing actual ultimate elements, which held together by motion make a continuum, but have a proper unity. However, his move raised two new difficulties: the mathematical inconsistency of the model, which should bring together the actuality of the parts and their quantitative infinity, and the impossibility of distinguishing a unitary body from a simple aggregate of parts, or atoms, without resorting to some kind of form.

Leibniz's minds are a first attempt to solve both problems from a new perspective. On one hand, in fact, minds give unity to the ultimate constituents of bodies, and keeping track of how the body has been created, make it distinguishable from other bodies with the same shape:

> We say that the effect involves its cause; that is, in such a way that whoever understands some effect perfectly will also arrive at the knowledge of its cause. For it is necessary that there is some connection between a complete cause and the effect. But on the other hand there is this obstacle: that different causes can produce an effect that is perfectly the same.

[67] Scholars' interpretations are discordant on this point. On the coexistence of matter and souls, see, for instance, Garber (2009a). The thesis of a wholesale separation from the start is maintained in Mercer (2001).

[68] The relation between simple substances and souls is discussed in detail in Garber (2009a, 2016).

[69] In phase I, the only metaphysical notion Leibniz allowed was a supreme mind, which is the ultimate cause of motion, and hence of interaction between bodies.

> For example, whether two parallelograms or two triangles are put together in the appropriate way (as is evident here) the same square will, as is clear, always be produced. Neither of these can be distinguished from the other in any way, not even by the wisest being. So, given a square of this kind, it will be in the power of no one – not even the wisest being – to discover its cause, since the problem is not determinate. The effect, therefore, seems not to involve its cause. So if we are certain, from some other source, that the effect does involve its cause, then it is necessary that the method of production must always be discernible in squares that have been produced. And so it is impossible that two squares of this kind should be perfectly similar; for they will consist of matter, but that matter will have a mind, and the mind will retain the effect of its former state. [*De summa rerum* 1676. A6.3. 490-1. Transl. Parkinson p. 51][70]

On the other hand, as metaphysical objects, minds are nonquantitative notions, and the problem of their mathematical representation simply disappears. In fact, on one level, we have the appearance of physical objects, that is the extended material bodies we perceive, and we can approximately represent using the quantitative objects of traditional geometry: a physical body will be idealized as a continuous, in(de)finitely divisible, geometric solid, every part of which is comparable with every other.

On a totally separate level, we have the metaphysical foundation of the same physical object, which we do not directly perceive, and cannot represent using traditional geometry:

> Le corps est un aggrégé de substances, et n'est pas une substance à proprement parler. ll faut par conséquent que partout dans le corps il se trouve des substances indivisibles, ingénérables et incorruptibles, ayant quelque chose de répondant aux ames. Que toutes ces substances ont tousjours esté et seront tousjours unies à des corps organiques, diversement transformables. Que chacune de ces substances contient dans sa nature *legem continuationis seriei suarum operationum*, et tout ce qui luy est arrivé et arrivera. [*Leibniz à Arnauld 23 March 1690*, A2.2. 311–12]

("The body is an aggregate of substances, and is not a substance strictly speaking. It is therefore necessary that everywhere in the body there be substances that are

[70] "Dicimus effectum involvere causam suam; id est ita ut qui perfecte intelligat effectum aliquem, etiam ad causae eius cognitionem perveniat. Utique enim necessaria quaedam inter causam integram et effectum connexio est. Sed contra obstat, quod diversae causae producere possunt eundem perfecte effectum, exempli causa, sive duo parallelogramma, sive duo [triangula], uti oportet, et hic apparet, componantur, semper idem plane quadratum prodibit; quorum alterum ab altero nullo poterit discerni modo; ne a sapientissimo quidem; ita ut in nullius ne sapientissimi quidem potestate futurum sit, ex dato quadrato ejusmodi invenire eius causam, quoniam problema non est determinatum. Videtur ergo effectus non involvere suam causam. Quare si aliunde nobis certum sit, effectum involvere suam causam, necesse est in productis quadratis modum productionis semper discerni posse Adeoque impossibile esse, ut duo quadrata eiusmodi sint perfecte similia, quia ex materia constabunt, ea autem mentem habebit, et mens retinebit effectum status prioris." As noted by Garber in commenting this quotation: "This would seem to lead directly to the later view that individual substances, complete beings, require a soul as the seat of their complete individual concept: there must be form in bodies in order for them to contain the marks and traces of their previous states" [Garber 2009b, p. 72].

indivisible, non-generatable and incorruptible, possessing something corresponding to souls. And that all these substances have always been and will always be attached to organic bodies, variously transformable. And that each of these substances contain in its nature *legem continuationis seriei suarum operationum*, and all that has happened to it and will happen to it.")

Summarizing, in phase IV, the transition occurs towards Leibniz's definitive theory of physical bodies, which are nothing but the phenomenal "expression" of the aggregation of infinite unextended metaphysical simple substances. Now, as we will show more in detail in our analysis of phase V, the way in which physical bodies express metaphysical substances is only an aspect of a more general situation in which the whole physics is grounded on metaphysics, rather than on mathematics, as it was before.

Phase IV in Mathematics

It is in mathematics that this separation has the most important consequences. In fact, once mathematics is no longer the foundation of physics, but at most provides an (approximate) description of it, it can be extended to include concepts which do not have any physical counterpart. In particular, lacking a physical model, these notions lack a geometrical representation too: since they cannot be shown in the phenomenal realm, they can only be imagined, or feigned.

In phases II and III, Leibniz's physical bodies were made of matter *and* motion: infinite assignable portions of a continuous material stuff held together and made actual by their unassignable endeavors of motion. A geometrical representation that would account consistently for both aspects turned out to be problematic, having to make the actuality of the unassignables coexist with the infinite divisibility of the continuum in assignable parts.

Gradually, Leibniz abandoned the attempt to keep them together: physical bodies have a natural representation as continuous geometrical extensions, while unassignable infinitely small quantities become imaginary notions, or fictions, and we will conclude the analysis of phase IV following the path of Leibniz's infinitely small quantities from traditional geometry towards fictionality.

The crucial step of this path is the awareness of the consequences of unassignability, namely the non-Archimedean nature of infinitely small quantities. In particular, being in no ratio to finite magnitudes, when compared with them infinitely small quantities can be ignored, without leading to any contradiction.[71]

We argue that the syncategorematic reading represents a step in Leibniz's path toward his mature conception of infinitesimals, but not the final result. This is evident from the reading of the notes he wrote in the years 1675/1676, and in particular of *De Quadratura Arithmetica* (*DQA*), Leibniz's longest mathematical work.

In DQA, three methods for the quadrature of a curve are employed: the traditional indirect Archimedean method of exhaustion, Cavalieri's method of indivisibles, and Leibniz's infinitesimal techniques. In his seminal study of *DQA*, Eberhard Knobloch

[71] The only requirement is that in deleting, and more generally in manipulating infinitely small quantities, one follows certain well-defined rules; see note 22.

considered as substantially equivalent Leibniz's and Cavalieri's method and argued that indirect Archimedean methods are furnished so as to justify these speedy but risky techniques. Leibniz himself warns the reader concerning the risks inherent in the method of indivisibles:

> J'ai pris plaisir à poursuivre ce raisonnement car il offre un exemple des précautions à prendre lorsqu'on raisonne sur l'infini dans la méthode des indivisibles. [*DQA* 1676 Prop. XXII *scholium* A 7.6 583, translated by Parmentier p. 177][72]

("I took pleasure in pursuing this reasoning because it offers an example of the precautions to be taken when reasoning about infinity in the method of indivisibles.")

We argue that infinitesimal methods are rigorous, while according to Leibniz, Archimedean methods must be handled with care. In fact, if we have to apply an exhaustion-like procedure to an infinite area, we must be careful, because some absurd results could appear.

With the introduction of *infinita terminata*, and the rules for computing with them (see footnote 83 below), Leibniz provides a tool for escaping such difficulties,

> et montre qu'on ne peut pas toujours s'empresser d'affirmer que la totalité d'un espace infini possède une certaine propriété, sous prétexte que celle-ci est toujours vérifiée par un nombre fini de parties. [*DQA* 1676 Prop. XXII *scholium* A 7.6 583, translated by Parmentier p. 177][73]

("and shows that one cannot always hasten to affirm that the totality of an infinite space possesses a certain property, under the pretext that this property is always verified by a finite number of parts.")

The DQA is sometimes used for supporting the claim that Leibniz's mature infinitesimals are inherently syncategorematic, so that the occurrences of the term "infinitesimal" are merely signs for traditional exhaustion procedures or else foreshadow "epsilontic" ones.[74] However, an attentive reading of DQA shows the opposite.

[72] "Libenter hanc contemplationem persecutus sum, quia specimen exhibet cautionis circa ratiocinia de infinito, et methodum indivisibilium"

[73] "ostenditque non semper ex partium finitarum perpetuo abscissarum proprietate quadam ad totius infiniti spatii proprietatem posse prosiliri"

[74] The idea of "syncategorematic infinitesimals" – a locution that never appears in Leibniz known writings but has been introduced in Arthur 2013 in order to explain Leibniz's mature conception of infinitesimals – comes from the idea of a syncategorematic infinite: just as a syncategorematic infinite refers to the procedure of indefinitely increasing a finite quantity, which remains in any case finite (see Sect. 2.2), syncategorematic infinitesimals refer to the procedure of indefinitely decreasing a finite quantity, which remains in any case finite. In other words, infinitesimals are a shorthand for Archimedean exhaustion-style procedures. It is clear that the definition itself of syncategorematic infinitesimals depends on the assumption that for Leibniz, the counterpart of infinitesimals are unbounded infinities. Based on Leibniz's own texts, we reject this assumption. Similarly, we reject the idea that Leibniz's infinitesimals foreshadow the current traditional theory of limits, usually referred as "epsilontic." On the epsilontic interpretation of Leibniz's infinitesimal calculus and its history, see in particular Breger (2008), pp. 187–189: "The connection between infinitesimals and what we now call epsilontics was *obvious enough* for 17th-century mathematicians" (p. 187).

In fact, it can be divided in two parts, containing respectively a traditional syncategorematic and a new infinitesimal approach.[75]

The first part of DQA (Prop I–X) does not contain anything new concerning infinitely small and infinite quantities. All one needs in order to understand propositions I–X is the syncategorematic stuff typical of Greek geometry: we take a finite quantity and then we divide (or we multiply) it indefinitely. We can go on indefinitely due to the properties of the continuum: at every step, we have a finite quantity, which at every step is smaller (bigger), without end. Both the notion of the asymptote (a line that can be made bigger and bigger without meeting the curve) and that of negligible error (a quantity that can be made lesser and lesser without becoming zero) belong to this traditional approach. Cavalieri's method of indivisibles is thought by Leibniz to fit into this scheme: a curvilinear area is filled with rectangles with infinitely small basis; since one can show that, diminishing the basis, the remaining part can be made lesser than any given quantity, the equivalence between the "sum" of infinite rectangles and the curvilinear area is demonstrated (in fact this is closer to Torricelli's method than Cavalieri's).

In most cases, the traditional method works perfectly, but there are instances where, as Leibniz explicitly says, it is not safe. In particular, it becomes "slippery" (lubrica) when one has to consider an infinite area, for instance, the one contained between a curve and its asymptote. In this case, one can reach a contradiction, and in Proposition XXII, he shows a typical case: an infinite area is proved to be equal to the same area minus a finite part[76]:

> On aboutira de la même manière, pour les autres hyperboloïdes, à un tout égal au tiers ou au quart d'une de ses parties. Voici une élégante manière de montrer combien sont périlleux les raisonnements sur l'infini lorsqu'ils ne sont pas pour ainsi dire guidés par le fil d'une démonstration. [*DQA* 1676 Prop. XXII *scholium* A 7.6 583, translated by Parmentier pp. 177–179][77]

("We will arrive in the same fashion, for the other hyperboloids, at a whole equal to a third or a quarter of one of its parts. Here is an elegant way of showing how perilous

[75] In fact, Leibniz introduces two novelties in DQA: (1) he introduces some "fictions" i.e., lines which are infinite and bounded. As we read in Prop. XI: "dans la mesure où elle s'appuie sur une fiction et aboutit sans difficulté dès qu'a été admise une ligne à la fois bornée (terminata) et infinie" [DQA, Prop XI, p. 99]. But also (2) he generalizes the method of indivisibles (see Prop. VI and Parmentier's footnotes, especially n. 2 p. 63). And in fact he calls Cavalieri's method "la methode des indivisibles ordinaire"). Here the novelty consists in the introduction of what Parmentier calls "rectangles intermédiaires, dont les arêtes ne correspondent pas aux points de la courbe" (DQA note 2 p. 63).

[76] "Eodem modo in aliis colligetur totum partis suae trientem aut quartam partem esse. Eleganti argumento quam lubrica sit ratiocinatio circa infinita, nisi demonstrationis filo regatur" (Translated by Parmentier). Historians often claim that it is Leibniz's method with infinitesimals that is not safe and therefore requires justification by means of an exhaustion like procedure (on this interpretative line, see Rabouin and Arthur (2020)). In fact here Leibniz is claiming on the contrary that only his direct method is safe, which does not involve unbounded infinities. There is currently a lively debate concerning the Leibnizian calculus; see e.g., Bair et al. (2021) and references cited therein.

[77] "Eodem modo in aliis colligetur totum partis suae trientem aut quartam partem esse. Eleganti argumento quam lubrica sit ratiocinatio circa infinita, nisi demonstrationis filo regatur." Here Leibniz is clearly referring to arguments using infinite wholes, rather than arguments using infinitesimals.

reasoning about infinity is when it is not, so to speak, guided by the thread of a demonstration.")

It is worth noting that the contradiction follows from having assumed that the quantities involved in the proof are always finite, at any step of the procedure. But this is exactly the crucial property of syncategorematic procedures and of the unbounded infinities they involve.[78]

By contrast, starting from Prop. XI, Leibniz lays the foundation of a new method, distinct from the traditional one, and which clearly has the purpose of avoiding ambiguity and contradictions related to the use of unbounded infinities[79]:

> Bien plus, à supposer que les questions dont je traite soient susceptible de démonstrations directes, je n'hésiterais pas à avancer qu'on n'en pourrait donner aucune qui n'admette ces quantités fictives, infiniment petites ou infinies, reportez-vous plus haut au scholie de la proposition VII[80]

("Furthermore, assuming that the questions I am treating are susceptible of direct proofs, I would not hesitate to assert that one could not give any [proofs] which do not exploit these fictitious quantities, infinitely small or infinite, see above at Scholium of Proposition VII.")

> [. . .] Le présent petit traité en fournira un exemple propre à convaincre de la fécondité de la méthode; ce que j'ai dit dans le scolie de la proposition 22 fournira d'autre part un exemple particulier de raisonnement sûr, là où la méthode de Cavalieri prise au sens strict n'est pas fiable [*DQA* 1676 Prop. XXIII *scholium* A 7.6 585-586, translated by Parmentier].[81]

[78] Although this demonstration has been used to argue the inherently contradictory nature of Leibniz's *infinita terminata* (see, for instance, Arthur (2013), pp. 556–558, where an early version of the proof is used), it actually proves the contradictory nature of *infinita interminata* rather than of *infinita terminata*.

[79] Significantly, Knobloch admits that contradictions are due to the use of, specifically, *un*bounded infinity: "Leibniz underlines that the method of infinite quantities is dangerous. We have to apply the thread of an indirect proof if we have in mind to rely on it. Why? Because the infinite is characterized in a privative way. In reality, there is no last point, no end, we have only relied on a fiction in order to admit it in mathematics." (Knobloch 1994, p. 270). But the fiction is not the slippery unbounded infinite: it is the reliable bounded infinite.

[80] Although they are not defined until Prop. XI, fictive infinite quantities are mentioned in the *Scholium* to Prop. VII. This fact seems to have led some readers to conflate the two methods. But in Prop. VII, Leibniz does not use any fiction: he merely notes fact that he has been forced to use a *reductio ad absurdum* because he does not know any direct method. In fact, he fears that no direct solutions are possible, unless one agrees to use fictive quantities, namely infinitesimals and *infinita terminata*: "j'ai même des raisons de craindre qu'on ne puisse pas le faire d'une manière naturelle et sans faire intervenir des quantités fictives, je veux dire infinies ou infiniment petites" (imo ratione habeo, cur verear ut id fieri possit per naturam rerum sine quantitatibus fictitiis, infinitis scilicet vel infinite parvis assumptis *DQA* VII scholium, translated by Parmentier, pp. 69–71).

[81] "Imo si quidem possibile est directas de his rebus exhiberi demonstrationes, ausim asserere, non posse eas dari, nisi his quantitatibus fictitiis, infinite parvis, aut infinitis, admissis. Adde supra prop. 7. schol. [. . .] Cujus specimen totus hic libellus erit si quis methodi fructum quaerit; securitatis autem excemplum peculiare dabunt quae diximus *schol. ad prop 22* ubi Cavalerii methodus crude sumta infida est." What may have misled some readers is Leibniz's reference to the method of indivisibles. They take this to be a reference to infinitesimals, whereas we argue that Leibniz is referring to exhaustion-type arguments.

("This little treatise will provide a suitable example to convince of the fecundity of the method; what I said in the Scolium of Proposition 22 will, on the other hand, furnish a particular example of reliable reasoning, where Cavalieri's method taken in the strict sense is not reliable.")

Here Leibniz furnishes an example where the traditional method is not reliable, whereas the introduction of Leibniz's fictions furnishes a more reliable method.

The main ingredients of Leibniz's method are bounded infinities (*infinita terminata*). Here the infinitely small quantities (μ) are fractions whose denominators are infinitely large but bounded quantities (μ)λ, both called fictions. It does not matter – Leibniz says – if these quantities are *in rerum natura*. Of course, for using them safely, one needs to provide the appropriate rules, indeed provided by Leibniz.[82]

These quantities (bounded infinities and infinitesimals) in the DQA are treated as different from what Leibniz calls indivisibles. In particular, Leibniz says that:

> Au demeurant il semblera à certains paradoxal de parler de Lignes infinies qui soient cependant bornées, je dois donc faire remarquer qu'il existe une grande différence entre indivisible et infiniment petit, et de la même manière une grande différence entre infini et non borné [*DQA* 1676 **Prop. XI]**[83]

("At any rate, it will seem paradoxical, to some, to speak of infinite Lines which are nevertheless bounded, I must therefore point out that there is a great difference between indivisible and infinitely small, and in the same way a great difference between [bounded] infinite and unbounded.")

Here Leibniz emphasizes the difference between indivisibles and infinitesimals, which supports our interpretation. Leibniz also wrote:

> La Géométrie des indivisibles est trompeuse si on n'y adjoint quelques précisions au sujet des infiniment petits; utiliser des points véritablement indivisibles comporte un certain risque et il faut au contraire employer des lignes qui, pour être infiniment petites, n'en sont pas moins des lignes et sont, par conséquent, divisibles. [*DQA* 1676 **Prop. XI]**

("The Geometry of the Indivisibles is misleading if one does not add to it some clarifications concerning the infinitely small; using truly indivisible points carries a certain risk and on the contrary it is necessary to use lines which, while being infinitely small, are nonetheless lines and are, therefore, divisible.")

[82] In particular, having constructed the infinite rectangle with basis (μ) and length (μ)λ, Leibniz proves that, depending on the properties of the curve, it can be: (a) finite, (b) infinite, or (c) infinitely small. The proof of (a) is made extending to the infinite rectangle some properties which hold for finite areas. The proofs of (b) and (c) are made using the rectangle xy where x is the "first ordinate" and y is the "first abscissa." Summarizing, Leibniz shows that if x: 1 = m: (μ)λ with (μ)λ infinitum terminatum, then x is infinitely small. if (μ): 1 = m: y with (μ) infinitely small, then y is infinite (terminatum).

[83] Note that the contrast is a chiastic one: indivisibles and unbounded go together, and infinitesimal and infinite (i.e., bounded infinite) go together, as is clear from the subsequent discussion.

This clearly establishes that when Leibniz is talking about indivisibles, he is not talking about infinitesimals.

In sum, in *De Quadratura Arithmetica*, Leibniz presents the infinitesimal method as more reliable than the Archimedean one, because the latter sometimes relies on infinite wholes which are contradictory. In better-known passages, however, he justifies his infinitesimal method by an appeal to Archimedean exhaustion. It is possible that the erroneous idea that in *De Quadratura Arithmetica* Leibniz speaks of unreliability of his method, rather than of other methods involving unbounded infinities, comes from these later passages.

In phase IV, one is far from the unproblematic approach of phases II and III, when Leibniz was convinced that, although unassignable, infinitely small quantities could simply be handled via the method of exhaustion. Now he feels the need to justify their legitimacy.

As sketched in our analysis of the *De Quadratura Arithmetica,* Leibniz's strategy consists of two steps. On one hand, he shields his unassignable infinitely small quantities from the accusation of not complying with the part-whole axiom, and in this way, he renders them consistent from a mathematical point of view. On the other hand, he introduces for them a peculiar *status*, that of "fictions," which holds together their mathematical consistency and their lacking of any physical counterpart.

Concerning the part-whole axiom, Leibniz specifies that only unbounded infinities (*infinita interminata*) contradict it, and for this reason are absolutely impossible.[84] By contrast, bounded infinities imply no contradiction, and for this reason are only accidentally impossible.[85]

Concerning the *status* of his unassignable infinitely small quantities, Leibniz assimilates them to other physically problematic but useful, well-defined, and well-known notions such as imaginary numbers, which appear in mathematics but cannot be exhibited or geometrically constructed, as we have shown at the end of phase III and as reaffirmed by Leibniz in phase IV in the following terms:

> I call *imaginary constructions* the constructions that we can feign (fingere), but we can show (exhibere) only with your mind. They are nevertheless possible [. . .]: we can imagine for instance a quantity that grows – or is shortened or is transformed or is moved – following a

[84] We know that already in 1672, Leibniz declared infinite wholes to be contradictory: "Hence it follows either that in the infinite the whole is not greater than the part, which is the opinion of Galileo and Gregory of St. Vincent, and which I cannot accept; or that infinity itself is nothing, i.e., that it is not one and not a whole." [*Notes on Galileo's Two New Sciences* 1672. A VI. 3, p. 168; translated in Arthur 2001, p. 9].

[85] "Therefore if the essence of a thing can be conceived, provided that it is conceived clearly and distinctly (e.g., a species of animal with an uneven number of feet, also a species of immortal beast), then it must already be held to be possible, and its contrary will not be necessary, even if its existence may be contrary to the harmony of things and the existence of the divine intelligence, and consequently it never will actually exist, but it will remain per accidens impossible. Hence all those who call impossible (absolutely, i.e., per se) whatever neither was nor is nor will be are mistaken." (*Confessio Philosophi* A VI 3, 128, transl. Sleigh).

> given law, to which apparently no "ratio" can be associated. And it can happen that one can find a physical or even a geometrical realisation (effectio) of a construction that at the beginning seemed imaginary. [*De descriptione geometrica curvarum transscendentium* 1675 A7.7 516][86]
>
> One must discuss if $\sqrt{-1}$ is nothing or if it contains a truth. In fact, even if it cannot be done, it can be thought, not in itself but using characters and analogy (I call this way of thinking a blind one). In fact, as incommensurables are such that their powers are commensurable, in the same way imaginary are such that their powers are real, and impossibles are such that their squares are possibles, like $\sqrt{-1}$, whose square is -1, even if we assume that in nature there is no quantity corresponding to that: in fact, it is enough that its character is useful, because together with other ones it can express something real. [*Imaginariae usus ad comparationem Circuli et Hyperbolae* 1675 A7.7 561][87]

Like imaginary numbers, unassignable infinitely small quantities are intrinsically not geometrically representable: how could one represent a non-Archimedean quantity in a continuous framework such as that of Greek geometry? Furthermore, they cannot be viewed as the idealization of some physical objects, which would not respect the harmony of things. Summarizing: since unassignable infinitely small quantities do not contradict the part-whole axiom, they are possible (more precisely, not absolutely impossible) notions, but since they cannot be exhibited – either in geometry or in physics – they are fictions. The same position will be reiterated by Leibniz in subsequent years:

> And some extractions of roots are such that roots are surd and they do not exist in natura rerum, and we call them imaginary, and the problem is impossible, as when our analysis shows that the requested point must be exhibited by the intersection of a specific circle and a specific straight line, in which case it may happen that this circle by no means reaches this line, and then the intersection is imaginary [. . .] There is a big difference between imaginary quantities, or those impossible by accident, and absolutely impossible ones, which involve a contradiction: e.g., when it is found that solving a problem requires that 3 be equal to 4, which is absurd. But imaginary quantities, or [quantities] impossible by accident, namely quantities that cannot be exhibited for lack of a sufficient condition, which is required for having an intersection, can be compared with infinite and infinitely small quantities, which are generated in the same way [. . .] And it is true that calculus necessary leads to them, and people who are not sufficiently expert in such matters get entangled and think they have reached an absurdity (*absurdum*). Experts know instead that this apparent impossibility [apparentem illam impossibilitatem] only means that a parallel line is traced instead of a

[86] "*Constructiones imaginarias* voco, quas fingere possumus, exhibere non nisi mente non possumus. Sunt tamen possibiles [. . .] tales sunt si imaginemur magnitudinem aliquam certa lege crescere aut contrahi aut transformari, aut etiam moveri, cujus reapse praescribendae nulla appareat ratio. Et fieri poterit aliquando ut constructionis quae initio imaginaria apparuit tandem physica aut etiam Geometrica effectio reperiatur." The passage was discussed also in Katz et al. (2021).

[87] "An autem quantitas $\sqrt{-1}$. sit omnino nihil, an vero contineat nescio quid discutiendum diligentius. Etsi enim non possit effici, potest tamen quodammodo intelligi, non seipsa sed ope characteris et analogiae, exemplo illius cogitationis quam caecam appello. Et vero quemadmodum sunt incommensurabiles quae sunt potentia commensurabiles, ita sunt imaginariae quarum potentiae sunt reales; seu impossibiles quarum quadrata sunt possibilia, ut $\sqrt{-1}$, cujus quadratum -1 etsi autem ponatur nihil omnino esse in natura tali quantitati respondens; sufficit tamen ejus characterem esse utilem, quia cum aliis junctus realia exprimit."

> straight line making the required angle, and this parallelism is the required angle, or quasi-angle [*Elementa nova matheseos universalis* 1683 A 6.4 520–521][88]

The idea is that traditionally Greek geometry was considered the natural idealization of physics, and Greek geometry did coincide with the whole mathematics.[89] Subsequently, mathematical notions were found which did not belong to Greek geometry – roughly speaking, Greek geometry became a subset of a larger mathematics – but the idea survived that the idealization of physics has to be Greek geometry. The elements belonging to the complement of Greek geometry, having no direct physical counterpart, are then accepted, but they are regarded as fictions, or imaginary notions.

3.2.5 Phase V (1677–. . .)

Phase V leads Leibniz to his ultimate theory of the composition of bodies, a theory in which the separation among mathematics, physics, and metaphysics is complete. In particular, Leibniz eliminates any residual ambiguity by providing a metaphysical foundation to any feature of a physical body. Not only the actuality and the unity of the parts but their physical extension too is now explained in term of metaphysical notions.

Basically, Leibniz's idea is to extend to physical composite substances his analysis of simple metaphysical substances. Simple metaphysical substances – which the mature Leibniz also calls monads – can be analyzed into an active force (*vis activa*), or substantial form, and a passive force, or prime matter.[90] In an analogous way, in phase V, Leibniz expresses both extended matter and substantial form of physical bodies

[88] "Et quaedam extractiones tales sunt, ut radices illae surdae nec in natura rerum extent, tunc dicuntur imaginariae, et problema est impossibile, ut cum analysis ostendit punctum quaesitum debere exhiberi per intersectionem certi circuli et certae rectae, ubi fieri potest ut ille circulus ad illam rectam nullo modo perveniat, et tunc intersectio erit imaginaria [. . .]. Multum autem interest inter quantitates imaginarias, seu impossibiles per accidens, et impossibiles absolute quae involvunt contradictionem, ut cum invenitur ad problema solvendum opus esse, ut fit 3 aequ. 4 quod est absurdum. Imaginariae vero seu per accidens impossibiles, quae scilicet non possunt exhiberi ob defectum sufficientis constitutionis ad intersectionem necessariae, possunt comparari cum Quantitatibus infinitis et infinite parvis, quae eodem modo oriuntur [. . .] quod adeo verum est ut saepe calculus ad eas necessario ducat, ubi harum rerum nondum satis periti mire torquentur et in absurdum se incidisse putant. Intelligentes vero sciunt apparentem illam impossibilitatem tantum significare, ut loco rectae angulum quaesitum facientis ducatur parallela; hunc parallelismum esse angulum illum seu quasi angulum quaesitum."

[89] Still in Leibniz's days, algebraic notions were viewed as a sort of symbolic "translation" of geometrical quantities, and a "rigorous" proof meant a geometrical proof. On this point, see Breger (2008), §3. Cf. Parmentier (1995), pp. 26–27.

[90] While prime matter, as pure passivity, cannot be further specified, Leibniz describes the active power, or *entelecheia*, of a simple substance in terms of a law, the *law of the series*, which expresses the inner states of the substance itself (see GP III, 66; 356; GP IV, 512). To explain the way in which the law of the series rules the sequence of the inner states, Leibniz uses the analogy of a mathematical sequence of numbers: "L'essence des substances consiste dans la force primitive d'agir, ou dans la loy de la suite des changemens, comme la nature de la series dans les nombres" (*Excerpta ex notis meis marginalibus ad Fucherii responsionem primam in Malebranchium critica*, 1676, A6.3. 326). On the relation between the law of the series and simple substances in general, see, for instance, Whipple (2010) and the bibliography quoted there.

in terms of forces: a primitive passive force, corresponding to matter – the "*primary matter* in the schools, if correctly interpreted"[91] – and a primitive active force, corresponding to substantial form. As for Aristotle, form and matter, together, constitute a substance, for Leibniz, primitive forces, active and passive, do the same:

> Primitive active force, which Aristotle calls first entelechy and one commonly calls the form of a substance, is another natural principle which, together with matter or [primitive] passive force, completes a corporeal substance. This substance, of course, is one *per se*, and not a mere aggregate of many substances, for there is a great difference between an animal, for example, and a flock. [*On Body and Force* (1702), AG 252][92]

As Aristotelian primary matter and form, primitive forces are causes in a wide sense, for they are responsible for the whole being of a physical substance, and consequently for its behavior, and its observable properties:

> Composite substance does not formally consist in monads and their subordination, for then it would be a mere aggregate or a being per accidens. Rather, it consists in primitive active and passive force, from which arise the qualities and the actions and passions of the composite which are discovered by the senses, if they are assumed to be more than phenomena. [*Leibniz to Des Bosses* (1716). See Leibniz (2007), AG 203–4][93]

In particular, mechanical properties of physical substances – namely their internal coherence and their reciprocal interactions, and therefore the local motions behind them – are due to peculiar properties of these primitive forces, which Leibniz calls derivative forces:

> By derivative force, namely, that by which bodies actually act on one another or are acted upon by one another, I understand, in this context, only that which is connected to motion (local motion, of course), and which, in turn, tends further to produce local motion. For we acknowledge that all other material phenomena can be explained by local motion. [*Specimen Dynamicum* (1695), AG 120][94]

As for metaphysical notions in general, we have direct access neither to primitive forces nor to derivative ones: at most, they can be partially understood by means of

[91] *Specimen Dynamicum* [GM VI, 237].

[92] "Vis activa primitiva quae Aristoteli dicitur ἐντελέχεια ἡ πρώτη, vulgo forma substantiae, est alterum naturale principium quod cum materia seu vi passiva [primitiva] substantiam corpoream absolvit, quae scilicet unum per se est, non nudum aggregatum plurium substantiarum, multum enim interest verbi gratia inter animal et gregem" (GP IV, 395).

[93] "Substantia composita non consistit formaliter in monadibuset earum subordinatione, ita enim merum foret aggregatum, seu ens per accidens, sed consistit in vi activa, et passiva primitiva, ex quibus oriuntur qualitates et actiones passionesque compositi, quae sensibus deprehenduntur, si plus quam phaenomena esse ponantur" (GP II, 517–518)

[94] "Vim ergo derivativam, qua scilicet corpora actu in se invicem agunt aut a se invicem patiuntur, hoc loco non aliam intelligimus, quam quae motui (locali scilicet) cohaeret, et vicissim ad motum localem porro producendum tendit. Nam per motum localem caetera phaenomena materialia explicari posse agnoscimus" (GM VI, 237).

analogical speech. In particular, if we read primitive forces, active and passive, as substances, then derivative forces, active and passive, must be read as their faculties (*facultés*), or ways of being (*façons d'être*).[95] If otherwise we read the primitive force in analogy with the law of the series (of the states of the substance; see note 91), then derivative forces can be related to the single terms of the series:

> Derivative force is itself the present state when it tends toward or preinvolves a following state, as every present is pregnant with the future. But that which persists, insofar as it involves all cases, contains primitive force, so that primitive force is, as it were [*velut*], the law of the series, while derivative force is, as it were, a determination which designates some term in the series. [*Leibniz to De Volder* (1704). Transl. Loemker][96]

At this point, Leibniz differentiates his derivative active force from scholastics' faculties, which are traditionally interpreted as purely passive powers (*dynameis*). Derivative active force, instead, is endowed with an active tendency, which naturally tends towards its fulfillment:

> Active force differs from the mere power familiar to the Schools, for the active power or faculty of the Scholastics is nothing but a close possibility of acting, which needs an external excitation or a stimulus, as it were, to be transferred into action. Active force, in contrast, contains a certain act or entelechy and is thus midway between the faculty of acting and the act itself and involves a *conatus*. It is thus carried into action by itself and needs no help but only the removal of an impediment. [*De primae philosophiae emendatione, et de notione substantiae*, 1694. Transl. Loemker][97]

The explanation is resumed at the beginning of the *Specimen Dynamicum*, where Leibniz insists on the notion of *conatus*, now called *nisus* and defined in a scholastic way as a disposition, or appetite, which completes the force:

> Elsewhere we urged that in corporeal things there is something over and above extension, in fact, something prior to extension, namely, that force of nature implanted (*inditam*) everywhere by the Creator. This force does not consist in a simple faculty, with which the schools

[95] "Les Puissances primitives constituent les substances mêmes, et les puissances derivatives, ou si vous voulés, les facultés, ne sont que des façons d'estre, qu'il faut deriver des substances" (*Nouveaux Essais*, IV.iii.6. A VI, 6, 379).

[96] "Vis autem derivativa est ipse status praesens dum tendit ad sequentem seu sequentem praeinvolvit, uti omne praesens gravidum est futuro. Sed ipsum persistens, quatenus involvit casus omnes, primitivam vim habet, ut vis primitiva sit velut lex seriei, vis derivativa velut determinatio quae terminum aliquem in serie designat" (GP II, 262).

[97] "Differt enim vis activa a potentia nuda vulgo scholis cognita, quod potentia activa Scholasticorum, seu facultas, nihil aliud est quam propinqua agendi possibilitas, quae tamen aliena excitatione et velut stimulo indiget, ut in actu transferatur. Sed vis activa actum quendam sive ἐντελέχειαν continet, atque inter facultatem agendi actionemque ipsam media est, et conatun involvit; atque ita per se ipsam in operationem fertur; nec auxiliis indiget, sed sola sublatione impedimenti" (GP IV 469).

> have been content, but is further endowed with *conatus* or *nisus*, attaining its full effect unless it is impeded by a contrary conatus. [*Specimen Dynamicus* 1695, AG 118][98]

Summarizing, in phase V, Leibniz reads extended physical bodies as the mere phenomenal "expression" of the aggregation of infinite unextended metaphysical simple substances. Here a simple substance simply means the union of an active force, or substantial form, and a passive force, or prime matter. On a purely metaphysical level, then, physical bodies too can be analyzed in terms of primitive forces, active and passive. In their turn, primitive forces are meant to act in virtue of certain faculties, which Leibniz calls derivative forces, active and passive. Finally, derivative forces "produce" all the observable physical effects. For instance, all manifestations of local motion come from derivative active forces, via their *conatus*, or *nisus*.

The actuality of derivative forces manifests itself in observable but phenomenal local motions:

> For, strictly speaking, motion (and likewise time) never really exists, since the whole never exists, inasmuch as it lacks coexistent parts. And furthermore, there is nothing real in motion but a momentary something which must consist in a force striving *[nitente]* toward change. Whatever there is in corporeal nature over and above the object of geometry or extension reduces to this. [**AG 119**]

In a similar way, the unity and self-sufficiency of metaphysical substances, namely of primitive forces, has its phenomenal expression in the physical extension of bodies, every part of which has a proper individuality.[99] In other words, due to its monadic origin, physical matter is not a continuous stuff, like geometrical extension is, but a contiguous one, every part being characterized and individuated by a different motion:

> As for the first point, it follows from the very fact that a mathematical body cannot be analyzed into primary constituents that it is also not real but something mental and designates nothing but the possibility of parts, not something actual. A mathematical line, namely, is in this respect like arithmetical unity; in both cases the parts are only possible and completely indefinite. A line is no more an aggregate of the lines into which it can be cut than unity is the aggregate of the fractions into which it can be split up. [. . .]
>
> But in real things, that is, bodies, the parts are not indefinite – as they are in space, which is a mental thing – but actually specified in a fixed way according to the divisions and

[98] "In rebus corporeis esse aliquid praeter extensionem, imo extensione prius, alibi admonuimus, nempe ipsam vim naturae ubique ab Authore inditam, quae non in simplici facultate consistit, qua Scholae contentae fuisse videntur, sed praeterea conatu sive nisu instruitur, effectum pleno habituro, nisi contrario conatu impediatur" (GM VI, 235).

[99] In Leibniz's words, "every part of matter is actually divided into other parts" [*Leibniz to Arnauld*, November 28-December 8, 1686. A2.2. 122. Transl. Ariew-Garber]; "In truth, matter is not a continuous thing but a discrete one, actually divided at infinity" [*Leibniz to De Volder*, October 11 1705; G II, 278. (A2.4. 303600). Transl. Loemker].

> subdivisions which nature actually introduces through the varieties of motion. And granted that these divisions proceed to infinity, they are nevertheless the result of fixed primary constituents or real unities, though infinite in number. Accurately speaking, however, matter is not composed of these constitutive unities but results from them. [*Leibniz to De Volder* June 30 1704; G II, 268. Transl. Loemker][100]
>
> In truth, matter is not a continuous thing but a discrete one, actually divided *ad infinitum*. [*Leibniz to De Volder*, October 11, 1705; G II, 278][101] And certainly every extended thing is divisible, in such a way that parts can be assigned in it, but in matter they are actually assigned, while in extension they are only potential, as in number. [*Ad Schedam Amaxariam*][102]

The crucial novelty, which solves the last remaining difficulties in phase IV, is that now all the ultimate "components" of physical bodies – namely primitive and derivative forces, as well as their tendencies – are metaphysical entities. And as metaphysical entities, the question of their geometrical representation simply disappears:

> Therefore, I concluded from this that, because we cannot derive all truths concerning corporeal things from logical and geometrical axioms alone, that is, from large and small, whole and part, shape and position, and because we must appeal to other axioms pertaining to cause and effect, action and passion, in terms of which we can explain the order of things, we must admit something metaphysical, something perceptible by the mind alone over and above that which is purely mathematical and subject to the imagination, and we must add to material mass [massa] a certain superior and, so to speak, formal principle. Whether we call

[100] "Quod primum attinet, eo ipso quod corpus mathematicum non potest resolvi in prima constitutiva, id utique non esse reale colligatur, sed mentale quiddam nec aliud designans quam possibilitatem partium, non aliquid actuale. Nempe linea mathematica se habet ut unitas arithmetica, et utrobique partes non sunt nisi possibiles et prorsus indefinitae; et non magis linea est aggregatum linearum in quas secari potest, quam unitas est aggregatum fractionum in quas potest discerpi [. . .] At in realibus, nempe corporibus, partes non sunt indefinitae (ut in spatio, re mentali), sed actu assignatae certo modo, prout natura divisiones et subdivisiones actu secundum motuum varietates instituit, et licet eae divisiones procedant in infinitum, non ideo tamen minus omnia resultant ex certis primis constitutivis seu unitatibus realibus, sed numero infinitis. Accurate autem loquendo materia non componitur ex unitatibus constitutivis, sed ex iis resultat."

[101] "Revera materia non continuum sed discretum est actu in infinitum divisum."

[102] "Et sane omne extensum divisibile est, ut partes in eo assignari possint, actuque sint assignatae in materia, potentiales vero sint in ipsa extensione, ut in numero." A similar statement is reiterated a few pages later: "Est enim ut saepe dixi dispositio compossibilium phaenomenorum, Geometriaque est possibilitatum ipsarum tractatio. Et ideo extensio ipsa possibilis sive continua non habet partes determinatas, non magis quam Unitas numerica; quod secus est de physicis, seu existentibus ubi divisiones sunt actu factae. Quemadmodum non datur minima fractio in numeris, ita nec minimum in Geometria, punctumque est extremum non pars. Sed in rebus ipsis dantur minima simplices nempe substantiae." (*Ad Schedam Hamaxariam*, ad. 16, in LH IV, 3, 5c, Bl. 1–2. Transcription by Massimo Mugnai and Heinrich Schepers).

> this principle form or entelechy or force does not matter, as long as we remember that it can only be explained through the notion of forces. [*Specimen Dynamicum* (1695), AG 125][103]

What has to be dealt with using mathematics is only the phenomenal "expression" of metaphysical forces, namely physical bodies and their interactions. As usual, dealing with physics, one must be aware that mathematical descriptions are idealizations, useful but necessarily approximate. For instance, Leibniz defines matter as a contiguous stuff but, as we mentioned in phase IV, contiguity is not a mathematical property. The better mathematical description of a contiguous physical body is still a continuous mathematical solid, where continuity still means, as in phase I, potentially infinite divisibility, and indefiniteness of parts.[104]

More generally, this holds for each physical notion involving extension – whether matter, time, or motion – which therefore admit a traditional geometric representation, and can be dealt with using the traditional tools of Greek geometry, and in particular the method of exhaustion, without any need for infinitesimal quantities. Of course, since one can solve traditional geometrical problems using infinitesimal calculus, one can solve cinematic problems using x, t, and dx, dt. But while x and t have a direct counterpart in a measurable, and geometrically representable extensions, dx and dt have no direct physical counterparts. In other words, even if space and time are only potentially infinitely divisible (without ever attaining infinitesimals), we can fictively introduce infinitesimals of space, or of time.

---

[103] "Hinc igitur, praeter pure mathematica et imaginatione subjecta, collegi quaedam metaphysica solaque mente perceptibilia esse admittenda, et massae materiali principium quoddam superius, et ut sic dicam formale addendum, quandoquidem omnes veritates rerum corporearum ex solis axiomatibus logisticis et geometricis, nempe de magno te parvo, toto et parte, figura et situ, colligi non possint, sed alia causa et effectu, actioneque et passione accedere debeant, quibus ordinis rerum rationes salventur. Id principium Formam, an ἐντελέχειαν, an Vim appellemus, non refert, modo meminerimus per solam virium notionem intelligibiliter explicari." (GM VI, 241–242). Cf. the quotations in footnote 64 and 66 For analogous statements, see, for instance, what Leibniz's wrote some years before, in his *Discourses on Metaphysics* (1686): "Mais la force, or cause prochaine de ces changemens est quelque chose de plus reel, et il y a assez de fondement pour l'attribuer, à un corp plus qu'à l'autre; aussi n'est ce que par là qu'on peut connoistre à qui le mouvement appartient d'avantage. Or cette force est qualque chose de different de la grandeur, de la figure et du mouvement, et on peut juger par là que tout ce qui est conçu dans les corps ne consiste pas uniquement dans l'étendue et dans ses modifications, comme nos modernes se le persuadent. Ainsi nous sommes encor obligés de rétablir quelques estres ou formes, qu'il ont bannies. Et il paroist de plus en plus quoyque tous les phenomenes particuliers de la nature se puissent expliquer mathematiquement ou mechaniquement par ceux qui les entendent, qui neantmoins les principes generaux de la nature corporelle et de la mecanique même sont plustot metaphysiques que Geometriques, et appartiennent plustost à quelques formes ou natures indivisibles comme causes des apparences qu'à la masse corporelle et étendue" (GP IV, 444. English translation in AG 51–52).

[104] "A continuum is a whole whose parts are indefinite, and so is the space if we abstract everything that is in it." [*Divisio terminorum*. . .1683 A6.4. 565]. The relation between continuity and indefiniteness of parts is at the basis of Aristotle's discussion of the potentially infinite division of the continuum, in *Physics* III.4–8 and VI.1, a discussion which Leibniz continued to appreciate far beyond his "aristotelian" phase I: "Aristote a fort bien expliqué le plein et la division du continu contre les atomistes" [*Remarques sur la doctrine Cartesienne* 1689. A6.4. 2047].

As we argued at the end of phase IV, this is finally the sense in which we interpret Leibniz's idea of fictionality: a mathematical notion is a fiction when it lacks a traditional geometrical representation and therefore has no physical counterpart.[105]

We conclude our analysis by observing that phase V offers a new perspective on the usefulness of fictions like infinitesimals, which Leibniz employs in an analogical way to speak of otherwise inexpressible metaphysical notions. For instance, in the *Specimen Dynamicus* (GM VI, 238), a *nisus* is described as an elementary, infinitely small solicitation, from the infinite repetition of which *impetus* arises. An analogous relation is described between the dead derivative force (*vis mortua*), to which the elementary solicitation belongs, and the living derivative force (*vis viva*).

Our analysis of Leibniz's approach to force is compatible with the analysis by Rutherford, who wrote:

> In the end, I propose, it is Leibniz's view that, in and of itself, force is not a mathematically representable property. To understand the sense in which force is real, we must turn to a different theoretical framework altogether, that of metaphysics, wherein force is represented as a modification of a substantial power, or principle of change. (Rutherford 2008, p. 257)

The connection with infinitesimal calculus together with the necessity of taking it as an analogy is acknowledged by Leibniz himself and made explicit in a 1698 letter to De Volder:

> By analogy with geometry, or my analysis, solicitations are as dx, speeds as x, and [living] forces are as xx, or $\int xdx$.[106]

And this is in accordance with Leibniz's belief that metaphysical notions elude our human faculties, and the way in which we can speak of them necessarily involves reasoning by *analogy*:

[105] In fact the introduction of infinitesimals, as well as other fictional mathematical notions, contributed to the release of algebra from geometry: "Leibniz avait adopté une nouvelle manière de pratiquer la géometrie. Le calcul entre ses mains n'était plus la traduction des figures et des problèmes mais devenait le vrai point de départ" (Parmentier 1995, p. 104). On this point, see also Sherry and Katz (2014): "In this respect Leibniz recognized a hidden power of algebra, realizing that it was more than a short hand for what could be expressed geometrically. As impressed as Leibniz was by imaginary expression for real roots, he was more impressed by the power of algebra, and more generally, symbolic thinking, to unify disparate domains" (p. 170). Even though he starts from different premises – that infinitesimals are compendia for Archimedean procedures and foreshadow the epsilontic approach to the notion of limit – an analogous conclusion is reached by Breger 2008 (pp. 195–198).

[106] "Ut ita secundum analogiam Geometriae seu analysis nostrae solicitationes sint ut dx, celeritates ut x, vires ut xx seu ut $\int xdx$" [GP II, 156].

> On ne doit point s'étonner que je tâche d'éclaircir ces choses par des *comparaisons* prises des mathématiques pures, où tout va dans l'ordre, et où il y a moyen de les démêler par une méditation exacte, qui nous fait jouir, pour ainsi dire, de la vue des idées. [*Théodicée*, § 242][107]
>
> ("One should not be surprised that I try to clarify these things by comparisons taken from pure mathematics, where everything goes in order, and where there is a way to disentangle them by a precise meditation, which makes us benefit, so to speak, from the view of ideas.")
>
> Je trouvay donc que leur nature consiste dans la force, et que de cela s'ensuit quelque chose d'*analogique* au sentiment et à l'appetit; et qu'ainsi il falloit les concevoir *à l'imitation* de la notion que nous avons des ames. [*Systeme nouveau* (1695)][108]
>
> ("I therefore found that their nature consists in the force, and that from this it follows something analogous with regard to feeling and appetite; and that thus it was necessary to conceive them in imitation of the notion that we have of souls.")

4 Conclusion

In this chapter, we have attempted to trace the evolution of Leibniz's thinking regarding infinitesimals, both in mathematics and in physics.

We have observed how Leibniz's increasing mathematical awareness led him to gradually abandon his initial scholastic position, centered around the idea of the potential infinite divisibility of the continuum, in favor of more informed reevaluations, that involve the notion of unassignability.

We have divided Leibniz's journey into five phases, which can be summarized as follows:

Phase I: Both in mathematics and in physics, Leibniz adopts a traditional syncategorematic approach: both extension and matter are continuous, which means that they are potentially infinitely divisible, and every obtained part is assignable. The problem arises of the actuality of the elementary constituents of physical matter.

[107] GP VI, 261–262. "je ne prends les mots dans ce sens extraordinaire que parceque je ne trouve point des termes plus propres pour m'exprimer" (*Additions à l'Explication du systeme nouveau touchant l'union de l'ame et du corps*, 1698. GP IV, 582). "L'Idée positive de cette substance simple ou Force primitive est toute trouvée, puisque elle doit toujours avoir en elle un progres reglé de perceptions, suivant l'Analogie qu'elle doit avoir avec notre ame" (Leibniz to Lady Masham 30 june 1704. GP III, 357). On the role of analogy in Leibniz's philosophy, see Rescher (2013), Chap. 7, and Pasini (2016).

[108] GP IV 479, translated in AG 139. Italics ours. Of course, it is not only the notion of force that cannot be translated in mathematical terms: think about the notion of simple substance, or that of hypercategorematic infinite, or even possible worlds etc.. . . and the mathematical analogies which, this notwithstanding, Leibniz employs to illustrate them: "Vous savés donc que lorsque les conditions d'un point qu'on demande, ne le determinent pas assés, et qu'il y en a une infinité, ils tombent tous dans ce que les Geometres appellent un lieu, et ce lieu au moins (qui est souvent une Ligne) sera determiné. Ainsi vous pouvés vous figurer une suite reglée de Mondes, qui contiendront tous et seuls le cas dont il s'agit, et en varieront les circonstances et les consequences. Mais si vous posés un cas qui ne differe du monde actuel que dans une seule chose definie et dans ses suites, un certain monde determiné vous repondra" (*Théodicée*, § 414, GP VI, 362–363).

Phase II: In an attempt to resolve the problem, Leibniz separates the treatment of physics from that of mathematics. He redefines matter as a continuous stuff infinitely divided – and not only divisible – into individual parts. Both actuality and unity of these parts are due to their conatus, or unextended amounts of motion. The geometrical counterpart of this physical situation is a hybrid in which the infinite divisibility of the continuum has to coexist with the actuality of unextended "fat points," which Leibniz identifies with Cavalieri's indivisibles. In this phase, unassignability is accepted, without any further elaboration.

Phase III: Perhaps dissatisfied with the conclusions reached in phase II, Leibniz introduces some variations. The most significant one is the inversion of perspective in physics: discreteness is considered a foundational notion in relation to continuity: physical bodies do not come from an infinitely divided continuous stuff but from the aggregation of discrete basic elements, that as in phase II are "glued" together by their conatus of motion. In mathematics, the situation is similar, with the only difference being that now points are extended, although unassignable. Apparently, in this phase, to keep together extended but unassignable quantities and assignable ones is not a problem for Leibniz. Unassignable quantities are not called fictions, nor referred to using cognate verbal forms.

Phase IV: Leibniz delves deeper into the concept of unassignability and further separates mathematical inquiry from physical inquiry. Unassignable quantities are useful in mathematics but cannot have a physical counterpart. In fact, he rejects the possibility that physical quantities are not all comparable to each other: a world containing some portion of matter which has an unassignable ratio to another portion would be less perfect than a world where all portions are comparable. Leibniz starts referring to unassignable quantities as "fictions" and links them to other "imaginary" notions, such as imaginary numbers, that are noncontradictory but do not admit any traditional geometrical representation, nor a physical counterpart. In physics, metaphysical explanations reappear alongside the mathematical ones, and in some cases, as a replacement for them.

Phase V: The separation between mathematics, physics, and metaphysics is gradually brought to completion. In particular, mathematics ceases to be the foundation of physics, and geometry ceases to be its natural description: the true essence of physics is metaphysics, and as such it is non representable. In particular, being extraneous to the category of quantity, metaphysical objects can be thought of as unassignable in a stronger sense, and without problematic consequences.

We are far away from the reassuring "syncategorematic" vision of the beginning: mathematical awareness had led Leibniz to remarkable achievements in mathematics, but it had also compelled him to introduce greater complexity in physics.

1 Introduction

René Thom belongs to a line of preeminent mathematicians who were thoroughly engaged in philosophy. After a brilliant but short career in mathematics culminating in the Fields medal, he devoted himself to philosophy, in the context of a return to the ideas of Aristotle, the philosopher of nature, of whom he considered himself a heir. Thom had a monumental program: to lay down the foundations of a new natural philosophy based on mathematics, and more particularly on geometry and topology. Natural philosophy, from his point of view, included physics, embryology, optics, hydrodynamics, biology, linguistics, ethology, semantics, psychoanalysis and other fields.

With his philosophical broad program, Thom was continuously an intriguing figure for linguists, psychoanalysts, biologists and philosophers of sciences, let alone mathematicians. He opened up with these fields a dialogue which, in the history of mathematics, is unprecedented by the width of its spectrum. Philosophers of various sciences discussed and argued with him on technical grounds, defending their ways of thinking while trying to understand his original program, which, after all, seems quite natural for a mathematician: describing nature using the fundamental ideas of topology, from the most basic notions of open and closed set, boundary, singularity of a differentiable function, to the more elaborate concepts of cobordism, structural stability, analytic continuation, etc.

Thom's philosophical program was initiated in his first published book, *Stabilité structurelle et morphogénèse* (Structural stability and morphogenesis) (Thom 1972), published in 1972, and it was continued in his *Modèles mathématiques de la morphogenèse* (Mathematical models of morphogenesis) (Thom 1974b), published in 1974 and his *Esquisse d'une sémiophysique: Physique aristotélicienne et théorie des catastrophes* (Smiophysics, a sketch; Aristotelian physics and catastrophe theory) (Thom 1990b) published in 1988. He wrote other books with a strong philosophical flavor. He also published a large number of papers on philosophy. I will quote several of them in the present chapter, and there are many more.

Thom explained at several occasions the reasons for his passage to philosophy, and I shall dwell on them in what follows. He was also thoroughly involved in the reflection on mathematical education, and he participated to the major educational debates of his time, in particular, on the introduction of the so-called modern math in schools, in France and elsewhere, and on the new university programs. His article

Les mathématiques modernes: une erreur pédagogique et philosophique? (Modern mathematics: an educational and philosophical error?) Thom (1970) was translated into several languages and published in various journals. In both domains of pre-university and university programs, he was a defender of classical geometry, against the exaggerated weight given to algebra, set theory, information science and applied mathematics, and I will also comment on this in what follows.

The plan of the rest of this chapter is the following. In Sect. 2, I report on a few important moments from Thom's life. In particular, I review some events that were foreshadows of his future career as a mathematicians, and on certain factors that led him to abandon mathematical research and devote himself to philosophy. Section 3 is intended to situate Thom with respect to the Bourbaki group who was leading mathematical research and setting the rules for mathematical education in France, starting in the 1950s. At the same time, I indicate some of Thom's ideas on education and on mathematical writing. Section 4 is an overview of Thom's belief that, contrary to a common modern dogma, science is not quantitative but always qualitative, and of the debate that this belief generated among scientists. In Sect. 5, I comment on the relation of Thom's ideas with those of Aristotle, a filiation he has declared on many occasions and which he explains in several articles. In Sect. 6, I comment on the different assertions of Thom according to which he found in the philosophical ideas of Aristotle his own ideas on form, morphogenesis, and also the first notions of topology. In Sect. 7, I explain how Thom shared Aristotle's ideas on biology as a qualitative science, his ideas on hylemorphism, on homeomerous, and on anhomeomerous parts, and how he considered his program in this field to be also in the lineage of the one of the Stagirite. Thom established relations between the mathematical notion of stratification and other topological notions with ideas and concepts that Aristotle introduced in his work on the parts of the animals. Section 8 is concerned with Thom's ideas on the role played by the mathematical theory of singularities in the general framework of prediction in science. The theory of singularities becomes, from this point of view, a philosophical topic. Then follows a short Sect. 9, which contains a few notes on Thom's ideas on morphology applied to this field. The next two Sects. 10 and 11 respectively, are concerned with Thom's work on these two fields, which he viewed as domains of applications of his ideas on morphology. Section 12 is a glimpse into Thom's ideas on analogy, again, in the tradition of Aristotle. In the last section before the conclusion of this chapter, titled *A return to the classics*, I mention some ideas of three mathematicians that were predecessors of Thom's reflections, namely, Leibniz, Riemann and Grassmann, pointing out some connections with Thom's ideas.

2 *Vita*: From Mathematics to Philosophy

René Thom, at several occasions, recounted some events from his childhood that are related to the shift that occurred later in his intellectual activity, from mathematics to philosophy. I have already commented on this in the long biography (Papadopoulos 2018a) that I devoted to him in the first chapter of the book (Papadopoulos 2018b). In this section, I will give a short *Vita* of Thom, highlighting some episodes from his life that are connected with his journey from mathematics to philosophy.

René Thom was born in 1923 in Montbéliard, a small town in the East of France, now in the Burgundy-Franche-Comté region. The city was occupied by the Germans between 1940 and 1945[1], the period in which Thom was finishing secondary school and entering higher education. His parents owned a grocery store in Montbéliard. His father had a solid education, with a good knowledge of Latin, and he wrote poetry. Thom used to say that he gained his open-mindedness from having met people with very different backgrounds at the family grocery store. His parents encouraged him and his siblings to get a higher education.

Thom had the profile of a studious French schoolchild. From what he recounted, we know that he was not particularly brilliant at school, but some of his recollections from that period are harbingers of his life as a future mathematician, and I will mention some of them.

The first reminiscence dates from age ten or eleven, when Thom had set himself the task of systematically exploring what every theorem he knew on the geometry of three-dimensional space becomes in dimension four. He writes about this in an interview published in 1989 (Nimier):

> [This] was, if I may say so, my first attempt to do something original; but it was a way for me to understand, say, how a system of two planes in $\mathbb{R}^4$ was made, etc., and I think I had arrived to a pretty good intuition at that time. I was already seeing in four-dimensional space.[2]

The second fact I mention took place when Thom was thirteen or fourteen. We read in (Porte) that he came across a book on differential calculus in the public library of his hometown and was seduced by it. But Thom's main interest was Euclidean geometry. He writes in (Thom 1991c, p. 10): "I had a certain taste for Euclidean geometry which immediately attracted me very much." On the other hand, he had no taste for algebra, which, he says, was akin to certain automatisms. He later maintained this opinion on this field, a field which he considered "not very instructive," and he kept his ardor for Euclidean geometry, "our old Euclidean geometry," as he used to call it affectionately. On the same subject, he writes in (Thom 2004):

> There was one encounter that was quite decisive, and this was with Euclidean geometry in the ninth and tenth grades, where I really developed a taste for geometric thinking and proof.[3] I had made it a point of honor to find solutions to all conceivable problems in

[1] The city of Montbéliard oscillated a few times between France and Germany. From 1042 to 1793, it was part of the Holy Roman Empire, after which it was attached to France. It was occupied by the Prussians during the Franco-Prussian War of 1870, and liberated one year later by the so-called Bourbaki army, named after Charles-Denis Bourbaki (1816–1897), a general of the army of Napoleon III and son of the Greek colonel Constantin-Denis Bourbaki. The latter was educated in France and he served in the French army between 1787 and 1827. The pseudonym Nicolas Bourbaki, which was chosen randomly, refers to the name of general Bourbaki.

[2] The translations from the French are mine. For some more subtle sentences, I have included the French original in a footnote.

[3] I have transformed "classe de troisième et de seconde" of the French educational system into their equivalent in the American one.

> elementary geometry, in the geometry of the triangle, and this is why, since that time, I have kept a preference for Euclidean geometry that my colleagues and fellow mathematicians do not forgive me.

Besides geometry, Thom was intrigued by dynamics. In the interview (Nimier), he recalls his early interest and his motivation for this subject which, a few years later, became one of his favorite topics of reflection:

> Around age seventeen, I started being interested in dynamics. I don't remember on what occasion it was, but I had handed in a paper to my mathematics teacher, where I talked about the eternal return seen from a dynamical point of view, the theories of the eternal return. . . It was the idea that one could have of a space-time, a universe in which there would be the eternal return, that is to say, where the dynamics would be periodic, but I believe that it was almost the first time that I really thought things in terms of dynamics.

During his high-school years, Thom was equally fond of literature, poetry, history and science. He especially enjoyed reading Greek and Latin classical authors. In 1939, the question arose as to the choice of the second part of the *baccalauréat*.[4] Thom hesitated between the literature curriculum (which, in France, was called the *philosophy* section) and the science one (called the *elementary mathematics* section). He opted for the second. He explained his choice in his interviews with Émile Noël (Thom 1991c, p. 9):

> We knew that this section offered more opportunities than the first one; it was perhaps an illusion, but we were convinced of that. Above all, we were in 1939, at the beginning of the war, and our parents, who had fought during the First World War, used to tell us: "try be a artilleryman, you are less exposed than in the infantry!" To be an artilleryman, you had to have studied mathematics. This element probably weighed heavily in the birth of my mathematical vocation.

Thom obtained his *baccalauréat 2ème partie* in June 1940, in a *lycée* in Besançon, the large city close to Montbéliard. He was 16.[5] The period was hard for the Thom family, as for many in Europe, because of the Second World War. Furthermore, in those years, studying at high school represented a major cost for families. Thom, as a gifted child from a modest background, had obtained a small government scholarship for his education. We read in an interview reported on by Michèle Porte (Porte) that Thom's parents were really struggling to make their financial needs meet and to put their children through education.[6]

After his *baccalauréat 2ème partie*, Thom, together with his older brother, managed to cross the Swiss border, escaping from the Germans who had occupied

[4] In the old educational French system, the "baccalauréat," that is, the national high school diploma, had two parts. The "baccalauréat 2ème partie" corresponded to the last year in high school.

[5] Finishing school at age 16 is not unusual in France for a talented child.

[6] "Mon père a tiré le diable par la queue toute sa vie. . .Mes parents se sont vraiment saignés pour me faire faire des études."

Montbéliard and the region around it. Their stay in Switzerland was hard for they were penniless, and Thom recounts that they suffered there from starvation. With the help of the French authorities, the two brothers returned to France, and they ended up in Lyon, which was still in the free zone.[7] There, with the help of a family friend, who at the same time was a remote cousin, René Thom enrolled again in a high school, since he had nothing better to do, and he presented for the second time the *baccalauréat 2ème partie*, this time in the philosophy section.

After Thom graduated anew from high school, the preparation of the competition for entering the École Normale Supérieure was a natural choice for a talented young man like him, interested in science, literature, and philosophy. In France, such a preparation is offered by some selective high schools,[8] and Thom was admitted at the *Lycée Saint-Louis*, a prestigious secondary institution in Paris.[9] The preparation lasts in principle 2 years, in classes called *classe de mathématiques supérieures* and *classe de mathématiques spéciales*. Thom spent 3 years at the *Lycée Saint-Louis*, as his first attempt to enter the École Normale was unsuccessful and he had to repeat the year of *mathématiques spéciales*.

At several occasions, Thom recounted that right after he was admitted to the École Normale, he announced to the school director that rather than studying mathematics, his desire was to study philosophy of science, precisely, "in the path of Cavaillès and Lautman." The acting director at that time was the physicist Georges Bruhat, who strongly advised Thom not to follow this path, saying that it would be more useful for him to concentrate his efforts on the preparation of the *agrégation* in mathematics, cf. (Nimier).[10]

At the end of this chapter, I have included an appendix on the two philosophers of science Jean Cavaillès and Albert Lautman.

Thom's teacher at the École Normale was Henri Cartan, who took him under his tutelage and who played later an important role for him, especially at the beginning of his career as a mathematician.

Thom finished his studies at the *École* in 1946, after having passed the competitive examination of the agrégation. On the recommendation of Cartan, he was appointed to the University of Strasbourg.[11]

Thom was expected to submit a PhD thesis in the years that followed his appointment, and his first task was to find an appropriate research subject. He chose the field of algebraic topology. He explained later that it was easier for a beginner like him to work in a new discipline such as this one, where the ground to

[7] The city of Lyon was occupied later by the Germans, in November 1942.

[8] This is again peculiar to the French system, where the preparation of the entrance exams to the so-called *grandes Écoles* is done in specialized classes provided by some high schools, after the usual secondary school program.

[9] The *Lycée Saint-Louis*, before Thom enrolled there, had among its pupils André Weil, Laurent Schwartz, Gustave Choquet and several other preeminent mathematicians.

[10] This is a French diploma allowing, in principle, to become a teacher in a high school, but many students who plan to teach at university also pass this exam.

[11] In those times, one could enter academia in France without having a doctorate.

be explored was virgin and where there were still easily accessible open problems (Thom 1992d).

Thom's work on cobordism, which was to ripen in his mind in the few years following his arrival in Strasbourg, inaugurated the implementation of the methods of differential topology in algebraic topology, so that the subject of topology of manifolds became a combination of the two, differential and algebraic topology. In fact, at the time Thom entered the field of topology, both points of view (the algebraic and the differential) were in a state of rapid expansion and were undergoing major transformations.[12] Algebraic topology and the study of differentiable functions occupied Thom during his whole mathematical career. He obtained his doctoral degree in 1951, with a dissertation titled *Espaces fibrés en sphères et carrés de Steenrod* (Thom 1952). Cartan, who was officially Thom's thesis advisor, became involved in this work after Thom had written a first version, in order to correct the writing and make it intelligible.[13] Several letters exchanged between Thom and Cartan, edited by André Haefliger in the form of an article in volume I of Thom's Mathematical Collected Works (Thom 2017), concern the finalization of the writing of this thesis. The article contains excerpts from these letters, which show that Cartan strongly committed himself during the last months before the defense, to make the thesis understandable. The general impression that emerges from this correspondence, as well as from some letters dating from the previous year concerning a paper that Thom had submitted to Cartan for publication in the *Comptes Rendus de l'Académie des Sciences* (and which was eventually published in the proceedings of a conference), is that Cartan did not consider Thom capable of writing complete proofs. The correspondence between Thom and Cartan also shows that the latter consulted Samuel Eilenberg about Thom's dissertation and that Eilenberg began by expressing serious reservations about the validity of the proofs. In particular, in a letter to Thom, Cartan writes that Eilenberg "believes that it is absolutely impossible to know whether the theorems in question are correct, and consequently he considers

[12] Thom entered topology just after a major revival of this field that started in the 1930s. Topologists tried to classify manifolds and were looking for algebraic invariants. The notions of fibre space and fibre bundle became central in algebraic topology around the year 1950, and the topology of manifolds passed important milestones in the space of very few years: In 1956, Milnor proved the existence of exotic differentiable structures on 7-dimensional spheres. In 1961, he disproved the so-called *Hauptvermutung der kombinatorischen Topologie* ("main conjecture of combinatorial topology"), a conjecture formulated in 1908 par Steinitz et Tietze, asking whether any two triangulations of homeomorphic spaces are isomorphic after subdivision. The higher-dimensional analogue of the Jordan curve theorem (the so-called Jordan–Schoenflies theorem) was obtained in 1959–1960 (works of Mazur, Morse and Brown). In 1961, Smale proved the Poincaré conjecture for dimensions ≥ 7. The same year, Zeeman obtained the corresponding result for dimension 5, and the year later, Stallings for dimension 6. Thom considers that he arrived in topology at the right time. He writes in (Thom 2004): "I think that researchers who started in mathematics after 1960 have had infinitely more merit than than people like me who came along at just the right time."

[13] In those days, the task of the thesis advisor was generally that of a guarantor at the moment of the defense. In general, suggesting the subject of the thesis was not part of his role. At any rate, in Thom's case, it was not Cartan who proposed the topic of the work. I discussed this at length in the article (Papadopoulos 2018a).

that it would be very imprudent to publish them as they are in a thesis, without a true proof." We note incidentally that among the changes that Cartan advised Thom to make to his thesis, he recommended the elimination of a complete chapter which seemed to him very unclear and almost impossible to make readable in order to defend the thesis in due time,[14] hoping that Thom could at least work properly on the rest; in fact, this was a chapter on cobordism, a notion that Thom had introduced, and which became later the ground of the work for which he was awarded the Fields medal.

From an exterior point of view, the years Thom spent in Strasbourg (1947–1963) were those of his purely mathematical activity. In his interviews *Prédire n'est pas expliquer*, talking about this period, he summarizes it as, in the first place, that of an abandonment of philosophy in favor of mathematics, and also a period ending with a passage to mathematics as a tool for the description of the real world. This is how mathematics is used in *catastrophe theory*, a theory which he started to develop under the name *model theory*, whose goal was to provide a mathematical framework to ideas from all domains of knowledge, including the physical, social and biological ones.[15] He writes (Thom 1991c, p. 24):

> From 1950 on, I abandoned these philosophical preoccupations to devote myself to mathematics. This lasted until 1956-1957. Then I went through a phase of depression: progress in mathematics was made by others. They led to theories so algebraically complicated that I could not follow them anymore. I gave up. . . . But one must still do something! So I started to look for possible applications of the mathematical theories I knew. That is how I oriented myself towards catastrophe theory.

By the end of his stay in Strasbourg, Thom came across Christopher Zeeman's article *Topology of the brain*, an article which opened for him the door to new possibilities of representing the phenomena of life by mathematical models. He writes in his introductory talk of the 1982 symposium *Logos and Catastrophe Theory* (Thom 2004):

> The idea of biological modeling, I owe it to a certain extent to Christopher Zeeman who, in 61, had published an article called Topology of the brain, where he had shown the great theoretical possibilities of mathematical modeling of the most complex biological activities. I was very impressed by this article at the time.

At the Edinburg ICM (14-21 August 1958), Thom was awarded the Fields medal for his work on cobordism. Later, he described this problem as "to know when two manifolds can be deformed into each other without having singularities at any moment in this deformation." He considered that he had partially solved this problem. Concerning the prize itself, he declared in the interview *Paraboles et*

[14] This was in the summer of 1951. Cartan had arranged an invitation for Thom to Princeton for the following fall, and the thesis had to be defended before.

[15] The sub-title of Thom's book *Stabilité structurelle et morphogénèse* is *Essai d'une théorie générale des modèles* (An attempt for a general theory of models).

catastrophes (Thom 1980, p. 23): "It was a bit of a good fortune. I seized the right moment by being able to exploit the techniques that Cartan, Ehresmann, Serre and many others had taught me." He wrote in his autobiographical article (Atiyah and Iagolnitzer 1977) that ultimately, this prize left him with a bitter taste, because the work done was too little, compared to what others did after him. "In this sense," he says, "this prize represented for me a certain fragility that the future made even more visible. The consequence, if there was one, was only the invitation to the new Institut des Hautes Études Scientifiques." Indeed, Thom was offered a research position at this newly founded institute.[16] In (Thom 1991c, p. 27), he writes:

> I left Strasbourg and came, answering the call of the founder of the IHÉS. I had more leisure time; I was less preoccupied with teaching and administrative tasks. My purely mathematical productivity seemed to be on the wane and I began to focus more on the periphery, i.e., possible applications.
>
> In addition to optics, I wondered if there were some possible applications to biology. I finally understood where these exceptional singularities came from: they are linked to the fact that the trajectories of light rays are special, because they satisfy a variational principle, Fermat's principle; they have special properties that make caustics "catch" singularities more easily than they should. It is the transfer of this idea that led me to the theory of catastrophes, to the mathematical part that leads to it.

Thom declared at several occasions that his interest in forms arose from his observation of caustics.

Thom later had another "revelation," during a visit to the Poppelsdorfer museum in Bonn, when he saw plaster cast models of the various phases of the development of a frog embryo in the process of gastrulation. In particular, he noticed that some lines in these representations were, from the mathematical point of view, singularities that were familiar to him and he realized that the whole process may be interpreted using topology and geometry. He gave an interpretation of this beautiful geometry in terms of the unfolding of a wave front in an appropriate space that projects onto the ordinary space and later, he described all the process of development of the frog as a sequence of successive unfoldings of a singularity. This was the starting point for the application of his ideas on singularity theory to embryology (Thom 1991c, p. 111).

[16] The institute was founded by Léon Motchane (1900-1990), a Russian-born immigrant who started with small jobs in Switzerland and then Germany and who later became a wealthy businessman in banking and insurances. Motchane liked mathematics and he started studying them relatively late in his life, encouraged by Paul Montel. At age 54, he obtained a doctorate, with Gustave Choquet as supervisor, and he decided to dedicate an important part of his time and fortune to the foundation of a mathematical institute. He managed to obtain funding from several large private companies. The institute was founded in 1958, and Thom was among the first professors hired. The Institute was situated in Paris, in a two-room apartment in the Thiers Foundation, located in a private mansion in the 16th arrondissement, before moving four years later to Bure-sur-Yvette, in the domain called Bois-Marie, which became its permanent location. Today, the French government is the main source of funding for the IHÉS. Motchane represented Grothendieck for his reception of the Fields medal at the Moscow ICM (1966).

Thom's stay in Strasbourg lasted from 1947 to 1963, with a few breaks for visits he made to the United States, each for several weeks, and an interruption during the academic year 1953–1954, which he spent in Grenoble.

Thom introduced the word *catastrophe* in his book *Stabilité structurelle et morphogénèse* (1972), to denote an abrupt phenomenon that appears and disappears continuously. The work quickly became the reference for the theory that became known under the name *Catastrophe theory*. Speaking of this theory, Thom recalls the role of the optical experiments he conducted in 1959-1960 in Strasbourg as an impetus. He declares in his interview (Thom 1991c, p. 26):

> I came to [catastrophe theory] in a rather natural way: it was an evolution that led me, starting from a purely mathematical problem, the one called the generic singularities of a map, to see whether this theorem had physical applications. I was then at the University of Strasbourg and I had the opportunity to do some optical experiments. A colleague, who was a physicist, lent me some instruments, a spherical mirror, a prism and a dioptre. I was able to produce some caustics, and I made them vary by changing a little bit the position of the parameters; I observed how they were deformed. That is precisely the thing that interested me. [. . .] From there I started the theory of catastrophes: I realized that there were types, variations of caustics, that I did not foresee, and that I had to explain to myself the appearance of these singularities. It took me two or three years to understand where this came from. This is a banal phenomenon, but that is where I started from.

Optical caustics are curves that appear as envelopes of a beam of light rays reflected in a curved mirror. Later, in 1991, in his lecture titled *Leaving mathematics for philosophy* (Thom 1992c), Thom recalled that his first surprise during his experiments on optics was to see that the caustics obtained using a spherical mirror or a linear diopter give rise to singularities that he had not expected to see.

In 1961, during one of his trips to the United States, Thom met Salomon Lefschetz, who was working on structural stability, a notion that was introduced in the 1930s by Aleksandr Andronov and Lev Pontryagin. Several years later, in his introductory talk of the 1982 conference *Logos et théorie des catastrophes* (Logos and catastrophe theory) (Thom 2004), Thom wrote, regarding Lefschetz: "He understood very well the crucial importance of this notion and he did a lot to develop this theory in the Western circles." Later on, Thom used this concept in a decisive way in his mathematical and philosophical work, and it became a central element of his theory of morphogenesis. In fact, the title of his first book, published in 1972, whose aim is to provide a mathematical formalism to tackle general morphogenesis problems, is precisely *Stabilité structurelle et morphogénèse* (Thom 1972). He writes in the introduction: "This book is the first systematic attempt to think in geometrical and topological terms the problems of biological regulation, as well as those posed by the structural stability of any form." Thom, whose main objective became to understand form in nature, considered that only structurally stable morphologies and phenomena can be understood. He even tried to formalize

thermodynamics using the notion of structural stability, although he realized later on that he failed, and that some weaker notion of structural stability was needed.[17]

Let me make a parenthetical remark, concerning physics regarded by philosophers from Greek Antiquity, since, as we shall recall below, Thom often referred to them. Plato considered that there cannot be any knowledge of nature, that is, that physics does not exist, since the physical world is permanently subject to change, and it is impossible to have a real knowledge of something which is perpetually changing. Aristotle, on the contrary, in his *Physics*, was puzzled by evolution, and by things that are changing. His *Physics* is precisely a physics of motion and of change. Structurally stable phenomena makes a compromise between changing and unchanging objects. A dynamical system is structurally stable if, at each moment of its evolution, there is an interval of time around this moment such that the system obtained at any given time in this interval is identical to the original system.[18]

Thom's main philosophical program, that of describing nature and language in geometric terms, is already largely initiated in his book *Stabilité structurelle et morphogénèse* (1972). He writes in the Preamble: "This is a work that wishes to place itself in the line of a deceased discipline, namely *Natural philosophy*," and the reference to Aristotle is clear. A good half of this book is devoted to questions of embryology, where Thom proposes a formulation of this field using a geometric language.

In his second book, titled *Modèles mathématiques de la morphogenèse* (Thom 1974b), published in 1974, Thom defines morphogenesis as "the creative or destructive process of forms" (Thom 1974b, p. 10). Thom declares that his research on morphogenesis is based on two sources: on the one hand, his research in differential topology on structural stability, and on the other hand, his reading of embryology treatises. He considered that the applications of the theory he proposes go far beyond embryology and even biology, to include subjects such as physical chemistry, optics, hydrodynamics and others.

At IHÉS, Thom continued publishing on mathematics, but not in a classical style, that is, not on new theorems and proofs. Most of his mathematical works were addressed to biologists, philosophers, linguists and other nonmathematicians, and some of these articles were published in philosophical journals. Thom declared later that his drift toward biology and the other sciences was due in part to the presence of Alexander Grothendieck at IHÉS. He writes on this subject, in an autobiographical text (Atiyah and Iagolnitzer 1977, p. 82):

[17] Thom wrote: "initially, the theory of structural stability seemed to me to be of such scope and generality that with it, I could hope to replace thermodynamics by geometry, to geometrize in a certain sense thermodynamics, eliminating from thermodynamical considerations all the stochastic and measurable aspects, to retain only the corresponding geometric characterization of the attractors. It is certain that the instability phenomena of the attractors that have been discovered since then show that such a hope is false or, at least, that it would be necessary to weaken considerably the notion of structural stability." (Thom 2004, p. 587) (1989).

[18] The mathematical formulation of this notion asserts the existence of a conjugacy between a system and close-enough systems so that in some sense the two systems are similar.

> [. . .] Relations with my colleague Grothendieck were less agreeable for me. His technical superiority was crushing. His seminar attracted the whole of Parisian mathematics, whereas I had nothing to offer. That made me leave the strictly mathematical world and tackle more general notions, like the theory of morphogenesis, a subject which interested me more and more and led me towards a very general form of "philosophical" biology. The director, L. Motchane, had no objection (or if he did he kept it for himself). And so I ran what was known as a "crazy" seminar, which lasted the best part of my first year at the institute. Three or four years passed, during which I returned to Aristotle and classical Greek.

3 Thom, Bourbaki and Mathematical Education

At the École Normale Supérieure, Thom received from Cartan an education in the purest Bourbaki tradition. Soon after, in Strasbourg, he was seduced by ideas of Ehresmann, another eminent member of the Bourbaki group. But later, he became no less than an acerbic critic of the spirit that reigned in that group to which he owed his mathematical training. In his interviews *Paraboles et catastrophes* (Thom 1980*, p. 23*), reporting on a Bourbaki session to which, at the request of Cartan, he participated while the was still a student at the Énormale, he writes:

> According to the tradition, I had to attend a presentation of the texts and I was asked for my opinion in case of disagreement. . . . I was tired of listening (it was a bit boring!) and sometimes I even fell asleep during the sessions. In a sense, this was not a bad thing after all: later, in fact, I became an opponent of the Bourbaki view of mathematics. . . . They were really ultra-formalists! They presented mathematics in a rigorous, ascetic manner; but in doing so, they ended up dealing only with those portions of mathematics that were appropriate to this rigorous presentation. For this reason, much of the mathematics that was practiced at the time could only escape their attention. . . . Even today there are large sections of mathematics — the calculus of variations, partial differential equations, qualitative dynamics, etc. – that are considered as not "clean" enough (or "dead"!) to be included in the Bourbaki anthology. Thus, there is a genuine incompatibility between the Bourbaki repertoire and living mathematics. Bourbaki has embalmed the mathematics that he has reduced, so to speak, to a mummy!

Rigor, systematization, and axiomatization were among the notions at the foundation of the Bourbaki style. In the article *Modern mathematics: a pedagogical and philosophical error?* (Thom 1970), Thom expresses a certain retreat with respect to formalization, and he speaks of the limits of axiomatization. He protests against the disappearance of traditional Euclidean geometry (the geometry of the triangle) from French curricula, in favor of set-theoretic and algebraic theories, where students no longer take initiatives to solve construction problems, but learn abstract notions and apply blind algebraic recipes from a pre-established scheme. He then comes to the notion of "meaning," and he raises the question of why we do mathematics. Is it a gratuitous game, a random product of our brain activities, or is it a way to comprehend the universe? At the same time, he wonders about the meaning of the word "rigor" in mathematics. His answer is: "A proof is rigorous, if it arouses, in any sufficiently educated and prepared reader, a state of evidence that leads to adhesion" (p. 230). This is not the orthodox view on rigor, where a proof is rigorous if it consists of a logical sequence of implications, starting from well-known statements.

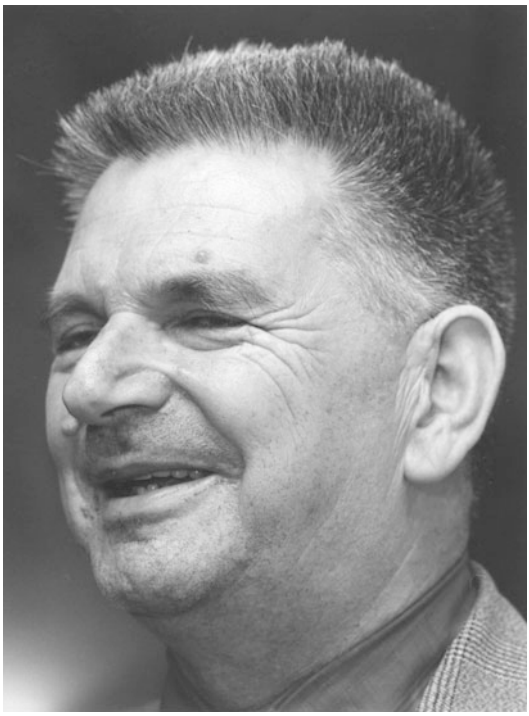

Fig. 1 René Thom in 1985. (Photo Gerd Fischer, Munich. Copyright Gerd Fischer. Source: Archives of the Mathematisches Forschungsinstitut Oberwolfach)

He recalls that the etymology of the word "theorem" is "vision," declaring that "there is no need for great axiomatic constructions or refined conceptual machineries to judge the validity of a reasoning." He writes (p. 232):

> There has been a lot of talking in recent years about the importance of axiomatization as an instrument of systematization and discovery. Yes, an instrument of systematization, certainly; but for what concerns discovery, the matter is more than doubtful. It is characteristic that, from the immense effort of systematization of Nicolas Bourbaki (which, by the way, is not a formalization, because Bourbaki uses a non-formalized metalanguage), no new theorem of any importance has emerged. And if researchers in mathematics refer to Bourbaki, they find their food much more often in the exercises—where the author has pushed the concrete material—than in the deductive body of the text. This must be said quite clearly: axiomatization is a research intended for specialists, and has no place either in secondary teaching nor at university (except, of course, for professionals who wish to specialize in the study of the foundations). This is why accusations of inconsistency addressed to Euclidean geometry are in fact irrelevant at the level of the local intuitive validity of the reasoning, which is the only level that matters.

On p. 236 of the same article, he writes:

> It is not certain that even in pure mathematics, every deduction can have a set-theoretic model. The ill-tamed paradoxes that undermine formal set theory are there to remind the mathematician of the dangers of the exaggerated use of these seemingly innocent symbols.

> Perhaps, even in mathematics, quality remains, and resists any set-theoretic reduction. The old Bourbakist hope, to see the mathematical structures emerge naturally from the hierarchy of sets, their subsets and their combinatorics, is probably only a fantasy. No one can reasonably escape the impression that the important mathematical structures (algebraic structures, topological structures) appear as data fundamentally imposed by the external world, and that their irrational diversity finds its justification only in reality.

Thom often referred to Gödel to remind us that absolute rigor in mathematics does not exist, the latter having shown that a completely formalized system of arithmetic (like a machine) is either inconsistent (leading to a contradiction), or incomplete.[19]

In a dialogue bearing the title *Métaphysique extrême* (Extreme metaphysics), Thom declares (Thom 2021, p. 86): "Formalists are people who always tell you: 'Oh, natural language is horrible, it tolerates every kind of ambiguity, it is not possible to do mathematics with it.' I have never done anything but natural language in mathematics, plus a few symbols from time to time."

In a series of lectures he gave in 1981, titled *Mathématiques essentielles* (Thom 1981), given at the Solignac Abbey, a medieval monastery in the Limousin (South of France), the main idea that Thom tried to communicate is that "what justifies the 'essential' character of a mathematical theory is its ability to provide us with a representation of reality." He declares (Thom 1981, pp. 2–3):

> The various branches that constitute mathematics are not all essential. By "real" I mean both the reality of the external world—whether it is given to us by the immediate perception of the world around us, or by a mediate construction as is scientific vision; that is to say, that the "real", in its most immediate form, is also apprehended by introspection—as an "immediate data of consciousness".

Thom reiterated this thesis in a talk he gave in 1982 at the École Normale, titled *Les réels et le calcul différentiel, ou la mathématique essentielle* (The reals and differential calculus, or essential mathematics) (Thom 1990d) and in several other writings. He was often accused of giving non-rigorous demonstrations, but these non-rigorous demonstrations were part of his style, which was that of a continuous search for meaning instead of rigor, and a refusal of any conventional way of writing mathematics.[20] In his interview with Jacques Nimier (Nimier), he expresses his doubts and hesitations, which were part of his philosophy:

> There are clean theories and dirty theories, and personally I always have more sympathy for a dirty theory. The clean theories are the theories where things are well presented, where the concepts are clearly defined, the problems more or less well defined as well. Whereas the dirty theories are the theories where one does not know very well where to go, one does not

[19] I would like to point out the interesting paper (Farmaki and Negrepontis 2021) by Farmaki and Negrepontis titled *The paradoxical nature of mathematics*, in which the authors argue that the deductive strength in Mathematics is strongly related to its paradoxical nature, and in fact, that it comes, maybe exclusively, from its proximity to the contradictory.

[20] See e.g., (Jaffe and Quinn 1993) and Thom's response in (Atiyah et al. 1994).

> know how to organize things and where the main directions are, etc. From this point of view, in fact, I have never been a Bourbakist, because Bourbaki likes clean things; whereas I think that it is necessary to get one's hands dirty, and sometimes even dirtier in mathematics.

As a passionate of topology in the sense of the theory of forms and their deformations, Thom was not attracted by algebra, nor by number theory, nor by set theory whose formalism had invaded mathematical writing. He adopted a way of thinking that included mathematics in a very broad perspective, that of motion, form and change of form. Gradually, he integrated the mathematical objects he had been working on into his new framework of thought, that of natural philosophy, where mathematics becomes the model of the physical and biological world. In his article *Les racines biologiques du symbolisme* (The biological roots of symbolism) (Thom 1978e), he returns to the opposition between algebra and geometry, this time associating topology with geometry:

> There is a certain opposition between geometry and algebra. The fundamental material of geometry, of topology, is the geometrical continuum; pure and unstructured extent is *par excellence* a "mystical" notion. Algebra, on the contrary, shows a fundamentally "diaeretic" operative attitude. Topologists are the children of the night; algebraists, on the other hand, wield the knife of rigor with perfect clarity.

Thom's judgment on algebra was shared by some other preeminent mathematicians. Michael Atiyah, referring to Goethe, considers that when a mathematician solves a question using algebra, he sells his soul. He writes in his article *Mathematics in the 20th Century* (Atiyah 2002):

> Algebra is the offer made by the devil to the mathematician. The devil says: "I will give you this powerful machine, it will answer any question you like. All you need to do is give me your soul: give up geometry and you will have this marvelous machine". [. . .] When you pass over into algebraic calculation, you essentially stop thinking; you stop thinking geometrically, you stop thinking about the meaning.

Mostly in reaction to the proponents of "modern mathematics" that imposed new programs in school and university curricula, Thom published, in 1962, an article on envelopes (Thom 1962), a classical subject which originates in the work of the seventeenth century mathematician Christiaan Huygens. The subject had been in the high school curriculum before the modern math reform, but had disappeared, certainly because of a difficulty it presented in comparison with subjects like linear algebra or analysis: in the study of envelopes, there is no general method, and one had to reason case by case. This was the kind of mathematics that Huygens preferred, and Thom followed him. Furthermore, this subject accounts for phenomena of life: Thom, again like Huygens, had observed the envelopes of light rays undergoing reflection or refraction on a surface or curve and the structure of the singularities they form. He was interested in the distinction between those that are stable or generic and those that are not, as well as in problems of classical plane geometry that the theory of envelopes leads to. Furthermore, Thom included the study of envelopes in that of

generic singularities of differentiable functions, one of his favorite subjects. In fact, in his auto-biographical article (Thom 1989b), Thom writes that he started the study of differentiable functions in order to understand envelopes.

4 Qualitative and Quantitative

From the beginning of the 1970s, Thom became involved in epistemology, in particular in the question of what is expected from science. In his books and articles, he expressed his ideas on the predictive attribute of theory, on the role of experimentation, and on analogy as a fundamental tool for reflection. From epistemology, he was gradually led to the great problems of philosophy. He turned more and more to Aristotle, with his categories and genera, expressing reservations about mathematical logic as the basis of thought, stressing the fact that it may lead to contradictions and making clear his preference to Aristotelian logic, a logic used in a natural way, and based on reality.

Thom liked Aristotle's informal and lively style. He writes in his *Esquisse d'une sémiophysique*: "The very style of Aristotle, far from the axiomatic precision expected of the logician, is that of a thinking that seeks itself, made of returns on oneself, always in struggle with its object; this testimony of a constant effort of thinking filled me with a kind of immense sympathy" (Thom 1990b, p. 13). He emphasized at several occasions that the fact that the theory he was proposing had no quantitative character was an echo of Aristotelian biology. This is the subject of his article *Qualitative and quantitative in evolutionary theory with some thoughts on Aristotelian Biology* (Thom 1996b). He used to describe Aristotle as "the apostle of the qualitative against the quantitative" (Thom 1990b, p. 172). In his 1988 article *Un rapport problématique: la rencontre théorie-expérience* (A problematic relationship: the theory-experiment encounter) (Thom 1988c), he contests the frequently repeated postulate that modern science was born at the beginning of the seventeenth century as a result of the development of the experimental method. Science, he insists, is the consequence of theoretical reflection, and no experimentation is useful without a causal analysis that sets its limits and allows for an adequate interpretation of the results.

Thom declared in 1984, in a communication to the Académie des Sciences titled *La méthode expérimentale: un mythe des épistémologues (et des savants)?* (The experimental method: A myth of epistemologists (and Scientists)?) (Thom 1985) that only two types of causal analyses are available for science: the first one, of Aristotelian origin, is that of efficient causes, based on natural language, explaining the phenomena by *ad hoc* entities, and the second one, linked to mathematics, essentially reducing the question of causality to the solution of a differential system whose solutions are completely determined by the initial solutions. In biology, he says, the first scheme is massively used to deduce precepts that have no demonstrative value. In the same article, Thom writes that the expression "experimental method" is not only a myth, but also an oxymoron: it contains a contradiction.

Indeed, he recalls that, while the word "method" refers to a direction of thinking, the word experiment originates in the latin word *experientia*, which means a trial.[21] Thus, rather than a "method," experimental science is a *pratice*, a practice, which according to Thom, comes under the heading of exploration carried out at random, if it is performed without a theory supporting it. The aim of experimentation would be, according to him, to find "that which one has not looked for," and, as such, it is illusory in many respects. He considers that approximation should not be part of science as an enterprise aiming at constituting a knowledge with universal validity. Specifically, Thom criticizes what he calls "contemporary biology," which uses the experimental method with no scruple.

A fierce debate followed Thom's lecture at the Academy, notably with the physicist Anatole Abragam, a fervent supporter of the experimental method, and who was also an academician. The text of Thom's lecture as well as Abragam's answer are published in the volume *La philosophie des sciences aujourd'hui* (Philosophy of sciences today), edited by J. Hamburger (Hamburger 1986).

Thom returned to this question several times in his writings. In his interviews (Thom 1991c, p. 130), he writes: "If one reduces science to a set of recipes that work, then, intellectually speaking, we are not better than a rat who knows that when a lever is pressed, food will fall into his bowl. The pragmatist theory of science brings us back to the situation of the rat in its cage." This is illustrated on the book cover (Thom 1991c) (Fig. 2).

In the same book (Thom 1991c, p. 79), Thom returns to a quote by Rutherford, "Qualitative is nothing but poor qualitative," which he strongly contests. He is convinced that the contrary is true. He writes: "All of topology is to be added to the chapter of examples of this conviction. How is a sphere different from a ball? This is really not quantitative. How is a circle different from a disk? It is not a question of quantity, it is a problem of quality."

One characteristic of Thom's theory of morphogenesis which will be criticized by the proponents of a theory of pure experimentation, is that it is a completely geometrical theory, "independent of the substrate of forms and of the nature of the forces that create them" (Thom 1972, p. 8). According to him, the fact that a theory is independent of the substrate makes it applicable at the same time to domains which are a priori very different from each other, like biology and linguistics. The ground space is simply an open set in a topological space, i.e., an abstract substrate, devoid of any matter. Thom writes: "This may seem difficult to admit, especially for experimentalists who are accustomed to cutting to the chase and continually struggling with a reality that resists them."

Thom said later that he ended up being a philosopher of science because of the need to respond to the criticisms directed toward catastrophe theory. He declared in an interview (Thom 1991c, p. 90):

[21] Etymologically, the word "method" consists of two words: the word is a combination of the words μετά, which means "after," or, "to follow" and ὁδός, which means a "way," or a "path."

Fig. 2 This book cover is Thom's representation of a predictive science: A rat who knows that if he presses a lever, food will fall into his bowl. (Figure © Flammarion)

I was indeed subjected to criticisms that were on the epistemological ground. I devoted myself for a while to the philosophy of science before engaging in more general philosophy [. . .]. I started somehow from the validity of the theory of catastrophes, and I came to be interested in the position of science in general, in what can be expected from it from the point of view of knowledge. It was there that I began to develop critical positions towards the so-called experimental method and the general belief in the virtues of experimentation as leading us to progress. I believe that experimentation by itself can hardly lead to progress. [. . .] But I found myself hitting a kind of wall: in a science like biology, for example, people refuse the theoretical necessity of imagination.

5 Thom's Rediscovery of Aristotle

Thom has always had a deep reverence for the philosophers of classical Greece. From the end of the 1960s on, he constantly referred to them. In his book *Structural stability and morphogenesis* (Thom 1972) which we already mentioned several times, he writes: "In fact, all the fundamental intuitions in morphogenesis are already to be found in Heraclitus; my unique contribution will be to have placed them in a geometrical and dynamical framework which one day will make them accessible to quantitative analysis."

Among the great figures of antiquity, Aristotle occupies a central place in Thom's work. On several occasions, he expressed his surprise for having found in Aristotle's writings ideas that he had previously held himself. He also shared with the Philosopher a boundless curiosity and a desire to understand all the phenomena of nature. In his book, *Semiophysics, a sketch*, which bears the subtitle *Aristotelian physics and catastrophe theory*, he writes: "It is only rather recently, almost incidentally, that I discovered Aristotle's work. I was almost immediately fascinated by this reading" (Thom 1990b, p. 12). In his *Esquisse*, published in 1988, he writes (Thom 1990b, p. 12):

> [. . .] If I add that I found in Aristotle the concept of genericity (ὡς ἐπὶ τὸ πολύ), the idea of "stratification" that we can glimpse in Aristotle the biologist in the decomposition of the organism into homeomers and anhomeomers, the idea of the decomposition of the genus into species as an image of bifurcation, we will agree that there was something to be astonished about.

Thom also discovered in Aristotle the idea of significant fact and significant form, which played an important role in his philosophy. He even found the essence of the mathematical notions of cobordism, genericity and stratification in the writings of the Stagirite, in particular in his biology. I shall talk about this in more detail in the next sections. The titles of some of Thom's articles are significant in announcing the subject at hand. Let me mention some of them, where the reference to Aristotle or Aristotelian ideas is obvious:

- *Mathématique et réalité: faut-il croire Aristote?* (Mathematics and reality: should we believe Aristotle?) (Thom 1987a, b).
- *Considérations sur la finalité: d'Aristote à Geoffroy Saint-Hilaire* (Considerations on finality: From Aristotle to Geoffroy Saint-Hilaire) (Thom 1986).
- *Les intuitions topologiques primordiales de l'aristotélisme* (The primary topological intuitions of Aristotelism) (Thom 1988b).
- Structure et fonction en biologie aristotélicienne (Structure and function of Aristotelian biology) (Thom 1990e).
- *Ésquisse d'une sémiophysique: Physique aristotélicienne et théorie des catastrophes* (Semiophysics, a sketch: Aristotelian physics and catastrophe theory) (Thom 1990b).
- *Causality and finality in theoretical biology: a possible picture* (Thom 1989a).

- *Homéomères et anhoméomères en théorie biologique d'Aristote à aujourd'hui* (Homeomerous and anhomeomerous since Aristotle until today) (Thom 1990c).
- *Matière, forme et catastrophes* (Matter, form and catastrophes) (Thom 1991a).
- *Actualité de la physique aristotélicienne* (Actuality of Aristotelian physics) (Thom 1992b).
- *Biologie aristotélicienne et topologie* (Aristotelian biology and topology) (Thom 1995).
- *Qualitative and quantitative in evolutionary theory with some thoughts on Aristotelian Biology* (Thom 1996b).
- *Histoire de la transversalité d'Aristote à la théorie des catastrophes* (History of transversality, from Aristotle to catastrophe theory) (Thom 1996a).
- *The hylemorphic schema in mathematics* (Thom 1997).
- *Comment la biologie moderne redécouvre la kinèsis d'Aristote* (How modern biology rediscovers Aristotle's *kinesis*) (Thom 1998).
- *Aristote topologue* (Aristotle as a topologist) (Thom 1999).

I will highlight several ideas that lie behind these works in the next section. Here I will only make a few comments on some papers in this list.

In the article *Actualité de la physique aristotelicienne* (Thom 1992b), Thom starts by pointing out a few principles from Aristotelian physics that can be found in an equivalent form in catastrophe theory. He dwells on the distinction that Aristotle makes between the phenomena that take place in the celestial, or "supra-lunar" world, and those of the sub-lunar one. The former is governed by God-given uniform circular motions, whereas the latter is subject to one great principle, namely, the effort of the four elements (fire, air, water and earth) which moves them toward what Aristotle calls their "natural place." It is in this distinction that Thom finds the origin of Aristotelian physics. He makes a comparison between this division and the modern classification of dynamical systems into reversible Hamiltonian ones and irreversible gradient-like dissipative ones. This leads him to present Aristotelian physics in an axiomatic way. He starts with an axiom of existence of entities (*ousiai*), continuing with their division into primary and secondary ones: The first ones include the living being, identified with a three-dimensional topological ball separated from the exterior world by a boundary (the skin), and the second ones are only "qualities" that affect the primary ones. The other axioms concern the *state* of an entity, the notion of *power*, and the *natural* transformations between entities. Entities interact with each other, and qualities are classified according to *genus*. The analogy between the major concepts of Aristotelian physics and those of catastrophe theory is outlined in terms of a few correspondences and principles:

(1) Natural place ↔ genericity;
(2) genus decomposition ↔ bifurcation;
(3) homeomerous/anhomeomerous ↔ regular and irregular point in a morphology;
(4) biological organization ↔ stratification;
(5) The continuity assumption;
(6) Form is the boundary of matter.

The fact that in Aristotle's *Physics*, form is the boundary of matter, is an idea that Thom interprets using his background as a topologist. He writes (Thom 1992b, p. 93) that the ambition of catastrophe theory is to keep this Aristotelian flexible scheme. We shall dwell on this in the next section.

I will review now some ideas of Thom on form.

Thom was, like Aristotle, a philosopher of form. Understanding form and its evolution, which Thom connected with his research in the topology of manifolds and function spaces, became an obsession for him in his philosophical works. He highlighted several passages in which his predecessor discusses form. In the *Metaphysics*, Aristotle writes that what makes the essence of an object is its *form* (Aristotle 1928) 1032b1-2, 1035b32. In the *De Anima*, he maintains that the soul is the form of a living being (Aristotle 1927) (412a11). In the *Physics*, he writes that potentially, flesh or the bone do not have yet their own nature and do not exist by nature, as long as they have not received the form of flesh and bone, that is, a definable form, that which can be stated to define the essence of the flesh or the bone (Aristotle 1930) (193b).

In the *Esquisse*, Thom talks about Aristotle's theory of hylemorphism, to which he adheres completely. This is a theory which considers that any being (object or individual) is composed in an indissociable way of matter (*hylé*, ὕλη) and of form (*morphè*, μορφή), matter being, for him, essentially something in power, a substrate which awaits to receive a form, in order to become a substance, the substance of being, or being itself. Thom notes that the word ὕλη was originally used to designate shapeless wood, and that it is to Aristotle himself that we owe its introduction in philosophy, while the latter was putting forward the notion of continuity, both for matter and for form. Thom writes on this topic (Thom 1990b, p. 12):

> Of course, I knew that the hylemorphic scheme which I use in the formalism of catastrophes had its origin in the work of the Stagirite. But I was unaware of the essential point, namely, that Aristotle had tried, in the *Physics*, to build a theory of the world based not on number, but on the continuum. He had thus realized (at least partially) the dream I have always had of developing a "Mathematics of the Continuum" which takes the continuum as its starting point, if possible, without any recourse to the intrinsic generativity of number.

Talking again about form in Aristotle, Thom writes in (Thom 1991c, p. 53):

> I see matter in an Aristotelian perspective, a kind of continuum that can acquire form. Form can be external, visible, or internal. The internal form is what one would call, from the semantic point of view, a quality. Aristotle's *materia signata* is a matter provided with quality. I think that any quality can be seen precisely, to a certain extent, as a spatial form, an extended form in an abstract space. The original matter, if I may say so, is a bit like Aristotle's raw material, it is the substrate which can receive any kind of quality, any predicate. The raw material is a kind of idealization which, very quickly, acquires qualities, forms.

Thom declared several times in his writings that he shared with Aristotle the conception of the soul as the form of the body. He comments on this in (Thom 1991c, p. 100):

> The capacity of a body to be the support of a soul is something that presents itself as a structure or as a law of a formal nature, associated precisely with form in the morphological sense, in the spatiotemporal sense of organization. The whole is obviously linked to the form of the flows running through the organism: blood, neuronal, or more generally metabolic: for me all this is form, and something comes out of it as a residual form with an organizing character: the soul. But the structure, the character (intrinsic in a certain sense) of this residual form, like the result of a formal structure, originates in this gigantic object that is the consideration of the form of all the molecular and physical movements of our organism.

6 Topology from an Aristotelian Perspective

In his books and in several articles, Thom highlighted and commented on several passages in the works of the Stagirite which support his conviction that the latter was aware of basic notions of topology. He declared in particular that a careful reading of Aristotle's *Physics* shows that the latter understood the topological distinction between a closed and an open set. The reader might try to imagine what kind of intuition can one have on the notion of open and closed set and the distinction between them if one does not have the language of set theory and topology. Thom writes in his *Esquisse* (Thom 1990b, pp. 167–168):

> A careful reading of the *Physica* leaves little doubt but that [Aristotle] had indeed perceived this difference. "It is a whole and limited; not, however, by itself, but by something other than itself" (207a24-35)[22] could hardly be interpreted except in terms of a bounded open set. In the same vein, the affirmation: "The extremities of a body and of its envelope are the same" (211b12) can be identified, if the envelope is of a negligible thickness, with the well-known axiom of general topology: "Closure of closure is closure itself" expressed by Kuratowski at the beginning of this century. This allows the Stagirite to distinguish two infinites: the great infinite that envelops everything and the small infinite that is bounded. The latter is the infinite of the continuum, able to take an infinity of divisions (into parts that are themselves continuous). Whence the definition he proposes: "The infinite has an intrinsic substrate, the sensible continuum" (208a).

Chapter 7 of Thom's *Esquisse* is titled *Perspectives in Aristotelian biology*. The first part concerns topology and bears the title *The primordial topological intuitions of Aristotelianism: Aristotle and the continuum*. It starts as follows (Thom 1990b, p. 165):

> We shall present here those intuitions which we believe sub-tend all Aristotelianism. They are ideas that are never explicitly developed by the author, but which—to my mind—are the framework of the whole architecture of his system. We come across these ideas formulated "incidentally" as they were condensed into a few small sentences that light up the whole corpus with their bright concision.

[22] Here and in the following, while I am giving the relevant passages in Aristotle, I am translating Thom's interpretation of the passages in Greek.

In his articles *Les intuitions topologiques primordiales de l'aristotélisme* (Thom 1988b) and *Matière, forme et catastrophes* (Thom 1991a), Thom returns to these matters, explaining that the modern topological distinction between an open and a closed set is also expressed in Aristotle's distinction between form and matter, and between actuality and potentiality. We mentioned this concerning his distinction between actual and potential infinity. He declares that the difference between the notion of bounded and unbounded open set in Aristotle's philosophical system lies in the fact that the former may exist as a substrate of being whereas the latter cannot (Thom 1988b, p. 396). He notes the presence of the notion of boundary in formulae such as: "Form is the boundary of matter," (Thom 1988b, p. 398) and "Actuality is the boundary of potentiality" (Thom (1988b), p. 399) and (Thom (1991a), p. 380). He points out that the paradigmatic substance for Aristotle, which is the living being, is nothing else than a ball in Euclidean space whose boundary is a sphere, that is, a closed surface without boundary. Shapeless matter is enveloped by form – *eidos* – in the same way as the boundary of a bronze statue defines its form. The boundary of a living organism is its skin, and its "interior" exists only as a potentiality.

The distinction between openness and closeness in the topological sense in Aristotle's works is also pointed out by Thom in his discussion of homeomerous and anhomeomerous parts of animals, which we review in Sect. 7 below, in the context of Aristotle's biology.

Another guiding idea in Thom's philosophical work which has an Aristotelian origin is the opposition between the discrete and the continuous. He declares, about this opposition: "For me, the fundamental aporia of mathematics is indeed in the opposition discrete-continuous. And this aporia dominates at the same time all thought" (Thom 1991c, p. 81). In this interview, he recalls Zeno's paradox supported by the story of Achilles and the tortoise and he declares:[23]

> The continuous is in a way the universal substratum of thought, and of mathematical thought in particular. But one cannot think anything effectively without having something like the discrete in this continuous unfolding of the mental processes: there are words, sentences, etc. The *logos*, the discourse, is always discrete; there are words entering in a certain succession, but discrete words. And the discrete immediately calls for the quantitative. There are points: we count them; there are words in a sentence: we can classify them quantitatively by the grammatical function they occupy in the sentence, but there is still an undeniable multiplicity.

Thom basically believed in the continuous character of the universe, of phenomena and of their substrate. Discontinuities only operate on the continuous. He was opposed to what he used to call a "modern vulgate," which comes essentially from information science and which says that everything is expressed in bits (Thom 1991c, p. 62). In the *Esquisse d'une sémiophysique* (Thom 1990b, p. 172), there is

[23] I take this opportunity to point out an extremely interesting interpretation of Zeno's paradoxes by S. Negrepontis in (2019), based on a thorough interpretation of Plato's dialogue *Parmenides*. In short, Negrepontis' explanation is that Zeno's aim in his argumentation is to show that the sensible Beings are separate from the true/intelligible Beings.

a long passage in which he discusses Aristotle's decision to leave Plato's Academy, a decision which he explains by a disagreement with the master, concerning the notion of continuous. In particular, Thom writes that Aristotle's "revolt against his master is that of the topologist against the imperialism of the arithmetician." He writes: "Aristotle does not go into much detail about the way he sees the raw material. In my opinion, it must always be reduced to a continuum, to an extent. I am a universal topologist! I have a real metaphysics of the continuum" (Thom 1991c, p. 54).

The notion of boundary is another key idea which Thom found in Aristotelian physics. He writes in (Thom 1991c, p. 110):

> For Aristotle, the form of a physical object is something like its boundary; in the abstract sense of the definition, the *eidos* is also something like a form in an abstract space, with its boundary. There is intelligible matter, which in some way is compressed by its definition. *Orismos* means definition; it is almost the same word as *oros* which means boundary. This is quite remarkable. . . . To define is to draw the borders. I think that there's something quite profound about that intuition.

In the two articles *The primary topological intuitions of Aristotelism* (Thom 1988b) and *Aristotle as a topologist* (Thom 1999), Thom pushed his ideas to the point of finding Stokes' famous formula in the work of the Stagirite. He explained in particular how he found this formula in a notion of minimal limit of an "enveloping body" contained in Aristotle's Physics (211b 11-12), a formula that he translates as: "The edge of the enveloped body and the edge of the enveloping body are together." This identification of Stokes' formula with a formula of Aristotle is echoed again by Thom in his article *Matière, forme et catastrophes* (Matter, Form and Catastrophe) (Thom 1991a, p. 381), an article published in the proceedings of a conference held at the Unesco headquarters in Paris at the occasion of the 23rd centenary of the Philosopher. If we add to this that Thom foresaw in the latter the mathematical ideas of genericity, stratification and bifurcation, we will not be surprised to see the reference to Aristotle in the subtitle of the *Esquisse* (Thom 1990b, p. 13).

The notion of cobordism, which was at the center of Thom's work in the 1950s, is also incorporated into this philosophical framework *via* the notion of boundary, which is its primary element. He states in his 1992 interview *La théorie des catastrophes* (Thom 1992d):

> The whole unity of my work revolves around the notion of boundary, because the notion of cobordism is only a generalization of it. The notion of boundary seems all the more important to me today as I am interested in Aristotelian metaphysics. For Aristotle, the boundary is a principle of individuation. The marble statue is matter in the block from which the sculptor drew it, but it is its boundary which defines its form.

7 Aristotelian Biology

Like Aristotle, Thom was the philosopher of biology. And basically, biology, from Thom's point of view, was not far from topology, nor from philosophy: "The great problem of biology," he says in a 1992 interview on catastrophe theory

(Thom 1992d), "is the relationship between the local and the global. Knowing the organism, why the organs have this or that property at this point and not another, etc., that is the big problem." He then adds:

> The problem of the relation between the local and the global is a problem that is essentially philosophical, that has to do with extent; this problem is the object of topology. Topology is essentially the study of the means to make the junction between a known local situation and a global property to be found, or vice versa: knowing a global property of space, find the local properties, around each point. There is a kind of deep methodological unity between topology and biology.

In his article *Les mathématiques et l'intelligible* (The mathematics of the intelligible) (Thom 1975b), Thom introduces what he calls mathematical thought in the context of biology and anthropology, a thought that, according to him, goes beyond the usual language in describing external phenomena with their mixture of determinism and indeterminism.

Chapter 5 of Thom's *Esquisse* is titled *The general plan of animal organization*. It is in the lineage of the zoological treatises of Aristotle, expressed in the language of modern topology. Thom writes in the introduction: "This presentation might be called an essay in transcendental anatomy; by this I mean that animal organization will be considered here only from the topologists' abstract point of view." He adds: "We shall be concerned with ideal animals, stylized images of existing animals, leaving aside all considerations of quantitative size and biochemical composition, to retain only those interorganic relations that have a topological and functional character." In the same chapter, Thom returns to Aristotle's notion of homeomerous and anhomeomerous, in relation with the stratification of an animal's organism, formulating in a modern topological language the condition for two organisms to have the same organization. Aristotle considers this notion at the beginning of the *History of Animals* (Aristotle 1910): "Regarding the parts of the animals, some are non-composite: these are those which can be divided into *homeomers*, like flesh is divided into flesh; others are composed: these are those which can be divided into *anhomeomers*; the hand, for example, cannot be divided into hands, nor the face into faces." Thom explains that a homeomerous part of an animal (ὁμοιομερής) has generally a boundary structure constituted by anhomeomerous parts, which implies that the substrate of a homeomerous part is, topologically speaking, not closed. Mathematics, philosophy and biology are intermingled in this interpretation of a living organism, following Aristotle, with formulae like: "The opposition homeomerous-anhomeomerous is a 'representation' (a homomorphic image) of the metaphysical opposition: potentiality-act. As the anhomeomerous is part of the boundary of a homeomerous of one dimension higher, we recover a case of the application of *act as boundary of the potentiality*." (Thom 1988b, p. 400).

In Thom's words, an animal organism is a three-dimensional ball O equipped with a stratification which is finite provided we neglect the details that are too fine. For example, when we consider the vascular system, we may take into account only the elements that can be seen with the naked eye: arterioles and veinlets. Seen from

this point of view, the homeomerous parts are the three-dimensional strata: blood, flesh, the inside of bones, etc.; the two-dimensional strata are the membranes: skin, mucous membrane, periosteum, intestinal wall, walls of the blood vessels, articulation surfaces, etc., the one-dimensional strata are the nerves: vessel axes, hairs, etc.; and the zero-dimensional strata are the points of junction between the one-dimensional strata or the punctual singularities: corners of the lips, ends of hairs, etc.

This leads Thom to the definition of two organisms O and O' "to have the same organisation" by the existence of a homeomorphism h: $O \to O'$ that preserves this stratification.

Thom also developed his ideas on the stratification of an animal body in the series of lectures given in 1988 at the Solignac Abbey (Thom 1981). On p. 7 of these notes, he addresses the question of when two animals have isomorphic stratifications, and he uses for that the notion of isotopy between stratified spaces: Two sets E_1, E_2 have isotopic stratifications if there exists a stratification of the product $E \times [0, 1]$ such that the canonical projection p: $E \times [0, 1] \to [0, 1]$ is of rank one on every stratum of E, with $E_1 = p^{-1}$ (1) and $E_2 = p^{-1}$ (2). He considers that this notion is implicitly used by Aristotle in his classification of the animals, insisting on the fact that the latter neglected all the quantitative differences and was only interested in the qualitative ones.

Thom also talks about stratification in Aristotle in chapter 5 of his *Esquisse*, a chapter titled *The general plan of animal organization*, in relation with the notion of homeomerous introduced by the Stagirite. He gives this idea of stratification in biology an official status in his work, by defining his *phenomenological equivalence relation*, a relation which at the same time allows us to take a new look at Aristotle's classification of the elements of a living body. He writes in his article *Structure et fonction en biologie aristotélicienne* (Thom 1990e), that this allows "the identification of two anomalies by an isotopy between stratifications, either according to genus, or refined according to species."

In relation with Aristotle's classification of the parts of the animals, and more generally of a general plan of animal organisms, Thom revived a famous controversy that took place in 1830 between Geoffroy Saint-Hilaire and Cuvier, in which the former used a purely geometrical classification principle of animal organs whereas the latter defended criteria based only on function; see (Thom 1978c), an article in which Thom proposes an approach to this dilemma using catastrophe theory.

Genericity is another idea that Thom finds in Aristotle's biology. He declares in his 1992 interview *La théorie des catastrophes* (Thom 1992d) that Aristotle considered that what matters in the study of nature is not to know everything that can happen, but everything that happens most often. In the Metaphysics, as in other texts, the Philosopher speaks at length about the difference between what happens most often and what is only an accident (συμβεβηκός). He writes in particular that all science is either about what is always or what is most often; otherwise, he says, how could one learn or teach others?[24] Thom establishes a parallel between this and the

[24] *Metaphysics* (Aristotle 1928) 1027a20.

theory of singularities: we study generic singularities, and those can be classified; their number is finite. There are important pathological singularities, but since they are not generic, the general theory does not deal with them.

In the series of interviews *To predict is not to explain*, Thom returns to the homological Stokes formula $d^2 = 0$ and to its biological interpretation in terms of Aristotelian zoology: "The boundary of the boundary is empty; this is the great axiom of topology, of differential geometry in mathematics, but it expresses the spatial integrity of the edge of the organism." (Thom 1991c, p. 111)

Thom spent some time trying to teach biologists the fundamental notions of topology that he thought they may need. Several sessions of the courses he gave at Solignac were devoted to this subject (Thom 1981). His 1982 lecture *Les réels et le calcul différentiel, ou la mathématique essentielle* (Thom 1990d) at the École Normale contains a summary of what is needed for the biologist as a minimal mathematical background.

In the next section, we talk more about the status of singularities in Thom's philosophical system.

8 Philosophy of Singularities

The goal of Thom's article *Philosophie de la singularité* (Thom 1988a) is to show how the mathematical notion of singularity is used in our perception and description of the world. Not only this, but from Thom's point of view, our perception is essentially a perception of form, a transfer of topological structure from matter to our mind. Thom starts by making a connection between the mathematical notion of analytic continuation in the holomorphic setting and prediction in science. In complex analytic geometry, analytic continuation allows, from the knowledge of a function on some open set, to extend it to a larger set, the domain of holomorphy of the function. Thom views this as a sort of prediction: we predict the value of the function on a larger subset. He notes that what prevents a function from being extended further, depends on the singularities, on the boundary of the domain of holomorphy.

Another well-known notable fact is that a holomorphic function is determined by its singularities. This was already known to Bernhard Riemann. One form of the latter's famous *Existence theorem* says that one can reconstruct a meromorphic function from the knowledge of its singularities and its topological behavior at these singularities. Paul Montel, who has been Henri Cartan's doctoral advisor, emphasized the importance of characterizing a function of a complex variable in terms of its singularities. In the introduction to his *Leçons sur les fonctions entières ou méromorphes* (Montel 1932), he writes: "What characterizes a function, what distinguishes it from others, is the set of its singularities. What holds for functions also holds for concrete objects and living beings" (Montel 1932, pp. vi–vii).[25]

[25] Ce qui caractérise une fonction, ce qui la distingue des autres, c'est l'ensemble de ses singularités. Il en est des fonctions comme des objets concrets et des êtres vivants.

Another idea related to the fact that the singularities of a function give global information on it comes from Morse theory, one of whose fundamental principles is that a Morse function allows the reconstruction of a space out of some finite number of cells of a fixed type and the singularities of the function. Such ideas were part of the background that accompanied Thom throughout the rest of his life.

It is during his time in Strasbourg that Thom began to reflect on Morse theory, which, in fact, is the subject of his first article, a note in the Comptes Rendus (Thom 1949) published in 1949.[26] What fascinated Thom in this theory was, once again, the fact that one can use the singular points of a function to decompose a manifold into cells that have a standard type, and conversely, one can reconstruct the space from the information on the cells and their order in the values of the function. Talking about this kind of situation, Thom recalls an old formula of Descartes: "To reduce everything to situations that are simple enough to be described" (Thom 1992d). This is another idea that never ceased to fascinate him: how to make constructions out of simple things. Regarding simplicity, he writes again in *Paraboles et catastrophes* (Thom 1980, p. 66): "The whole 'philosophy' of catastrophe theory, its general scheme, is precisely this: *It is a hermeneutic theory which tries, in front of any experimental data, to build the simplest mathematical object that can generate it*."

In the article *Philosophie de la singularité* that we already mentioned, Thom motivates the use of analytic functions in physics, and the fact that they constitute the basis for prediction (via analytic continuation) by the fact that the symmetry groups of the laws of physics, such as those that govern particles and their interactions, are analytic. He also recalls that the notion of stratification, in mathematics, arises precisely in an analytic setting. Singularities govern the propagation of analyticity and at the same time they play the role of obstacle for this propagation.

Regarding singularities, we also mention that Thom also studied the notion of apparent contour of objects, contours which present singularities that he can classify. Observing apparent contours reminds him of the inhabitants of Plato's cave, chained and unable to move, only capable of watching shadows of world events that take place outside the cave, projected on the wall in front of them by the light of a fire burning at the entrance of the cave. He says that this is how we should interpret Hironaka's desingularization theorems.[27] He notes incidentally that the singular sets of apparent contours are naturally stratified spaces in which a hierarchy of singularities is manifested, and he mentions a relation between such a situation and the notion of unfolding, a central notion in his theory of elementary catastrophes. Talking about the biological and human world, he mentions the "archetypal

[26] Haefliger, in his article (Haefliger 1988), writes, before presenting the ideas contained in this note and its later developments: "This was not too early, because the administrators at CNRS wondered if it was necessary to continue to support this young mathematician who was so little productive. [Il était temps, car les responsables du CNRS se demandaient s'il fallait continuer à soutenir ce jeune mathématicien si peu productif.]

[27] In the 1970s, Heisuke Hironaka built a theory on the desingularization of of sub-analytic sets, showing that locally, any such set is a finite union of images of spheres glued together by real-analytic maps. The theory had been foreseen by Thom. See Hironaka's exposition in (Hironaka 1973).

singularities" that appear in embryology. He concludes the article by pointing out an opposition between singularities created as defects of an ambient propagative structure and singularities as a source of the propagative effect, a problem that, he says, is at the source of all scientific disciplines.

9 Topology and Ethology

In this short section, I briefly review the point of view of a researcher in bioethics, Yanick Farmer on the importance of Thom's morphological theories in epistemology and in the theory of ethics. This view is expressed in the article *Topologie et modélisation chez René Thom: l'exemple d'un conflit de valeurs en éthique* (Topology and modelization after René Thom: The example of a conflict of values in ethics) (Farmer 2010).

Farmer considers that the abstract (topological) setting of Thom's approach to science, based uniquely on morphology, answers the problem of the need for universality in the particular setting of ethology, by avoiding the problem of relativization that is inherent to the use of specific languages that are proper to particular cultures. The author mentions as an example the notion of *autonomy*, which is central in bioethics but which has different meanings according to the language and the culture where it is used. Thus, from the ethologist point of view, to study a particular phenomenon, one must first differentiate it from its environment, and here, the author, like Thom, speaks of the need for this phenomenon or event to have a *boundary*, and the *substrate* of the discussion becomes a mathematical space which may be assimilated to a 3-dimensional Euclidean space.

I refer the interested reader to Farmer's article, in which he develops his ideas on the subject, which constitute a step toward the use of Thom's theory in ethology, but I would like to quote the conclusion of this article, where the author refers again to Plato's cave passage (I am translating again from the French) (Farmer 2010, p. 386):

> The philosophical positions that stand in the background of Thom's theory of models seem to me to be faithful to the essence of the spirit of philosophy conceived by Plato in his allegory of the cave. They act like a liberation for those among us who, by the chains of knowledge and perceptual limitation, are bind to the surface of familiar objects described by ordinary language. For these prisoners who do not have at their disposal any other impressive technical mean than the strength of their gaze, Thom's philosophy offers an epistemological way of salvation. By challenging the methodological omnipotence of Reductionism, which forces knowledge to reveal the depthless secret of elementary entities, René Thom reminds us, like Plato before him, that the thinker of everyday life and of the familiar things, as long as he is willing to become a geometer, can also try to understand better, in order to act better.

10 Linguistics and Morphology

For René Thom, every science is determined by a morphological scheme, and linguistics is no exception. In his hands, linguistics becomes a topological field. This is the subject of the present section.

Thom was particularly interested in linguistics. He saw in this field, as in biology, a privileged ground for the application of his ideas on morphology, with simple archetypes, where words are considered as living organisms, starting with the initial cry of the newborn, passing through the first stammering and stuttering, and culminating in the articulated and reasoned language of the adult. Aristotle, who studied language in his treatises on animals, considered that it is this articulated language, and the fact that it makes it possible for man to hold a reasoned discourse, that separates man from the other animals.[28] In this respect, Thom also spoke of language as a "boundary," which, as we already pointed out, is a notion that accompanied him during all his life: Following Aristotle, he considered language as the boundary that separates man from the rest of the animals.

In 1971, Thom published his article *Topologie et linguistique* (Thom 1971), which also appeared 5 years later in Russia, translated by Yuri Manin. The article concerns the application of catastrophe theory to linguistics. Thom starts by exposing the idea developed by Ferdinand de Saussure, that linguistics is a system of signs that associates two elements: the "signifier," which, here, is the sound, or the written word, and the "signified," which is of psychological nature, and which is the mental representation of the concept associated with the sign. The signifier and the signified are considered by Thom as two morphological processes, and the whole approach of Thom is based on a transformation between morphologies, which allows us to give an explanation of the syntactic structure of a sentence thanks to its signified. He writes: "For lack of sufficient mathematical knowledge, semanticians did not get the idea that the morphology of the signified could be supported by a multi-dimensional space. Therefore they were reduced to very poor descriptions, inspired by the logical analysis of language." His first objective was then to describe the morphological structure of the signified. For this purpose, he used a known model, the neurophysiological model of Zeeman, which leads to a geometrical model of the succession of ideas in the "stream of consciousness" of the philosophy of introspection, with the existence of a structurally stable attractor. To summarize, Thom's major contribution in linguistics was certainly the fact of bringing into this field the morphological models that he used in a field like biology. We refer the reader to Thom's article *La linguistique, discipline morphologique exemplaire* (Linguistics, an ideal morphological discipline) (Thom 1974a).

Regarding the significant and the insignificant, Thom liked to repeat this fragment of Heraclitus, the philosopher of absolute motion: "The master whose oracle is at Delphi does not say, does not hide, but he signifies," which Thom paraphrases by: "Nature sends us signs that we have to interpret."[29] In this regard, Thom often recalls Aristotle, for whom Art imitates Nature and not the other way around.

[28] In the *Politics* (Aristotle 1908) 1253a9-10, Aristotle considers that what separates man from other animals is the fact that man is a reasonable animal, λόγον ἔχον, "endowed with logos," the word *logos* meaning here speech, or reasoned speech.

[29] Fragment B93, cf. (Héraclite 1988).

Let me note also, talking about language, form and Aristotle, that the question of form in language is also present in the *Problems* (Aristote 1993), a compendium attributed to Aristotle, made up of questions, some of them simple and others that are real open research problems, encompassing all topics of science (mathematics, biology, physics, optics, psychology, astronomy, etc.).[30] In problem 23 of section XI of the collection, it is said that "the voice is air receiving a certain form," – a form which often changes, and which then vanishes. Similarly, problem 57 states that the voice of a human being – who, among the animate beings, is distinguished by the fact that he possesses the gift of speech – can take a multitude of nuances and forms.

Between Aristotle and Thom, I wish to mention another mathematician-philosopher, Marin Mersenne, whose *Harmonie universelle* (1636) contains a book titled *Treatise of voice and of singing* (Mersenne 1965, pp. 1–88). This book consists of an exposition of the physiology of the voice, both in humans and in animals, in the pure Aristotelian tradition. The statement of Proposition IX[31] of this book is the following: "Voice is the matter of speech, and only man can speak." In the demonstration of this proposition, Mersenne develops the Aristotelian idea of matter and form in speech, writing in particular: "We make use of the voice to form speech, as sculptors make use of wood and stones to make images; for images or statues are made by the different figures which are given to the matter of which they are made: and speech is a harmonic perspective, to which the voice serves as a picture to receive all kinds of images, since words are the images of the notions of the mind." Speech, he adds, "is the form, ornament, and perfection of the voice, which can only be formed and figured into speech by man, as speech can only be formed into discourse by the mind."

All this is close to what Thom said four centuries later.

11 Psychoanalysis

In his *Sketch of a semiophysics*, Thom writes that one of his main objectives is "to clarify the analysis of the original psychical mechanisms of our species" (Thom 1990b, p. 16).

In 1990, Michèle Porte defended a doctoral dissertation in Paris whose title is *Psychanalyse et sémiophysique: Études épistémologiques en métapsychologie et en dynamique qualitative* (Psychoanalysis and semiophysics: Epistemological studies in metapsychology and qualitative dynamics) (Porte 1990). In this dissertation, the author uses Thom's catastrophe theory and his ideas on qualitative dynamics, and in particular, structural stability, to try to reformulate metapsychology. Her main thesis

[30] Although, as in well known, there is an uncertainly concerning the authorship of the whole treatise, there is not doubt on the fact that it belongs to the Aristotelian school and that it was inspired, if not completely written, by Aristotle himself.

[31] Mersenne's *Harmonie universelle* is organized into propositions and proofs, like in mathematical treatises.

is that Sigmund Freud's theories cannot be understood in a formalist and structural setting, but, on the contrary, in a dynamical setting of birth, persistence and vanishing of forms and the dynamics behind them. Thus, she proposes an interpretation of Freud's ideas using a morphodynamical model of psychical events, in the tradition of Thom. At the same time, she makes a confrontation between Freud's psychoanalysis and Thom's semiophysics.

Later, the same author published a systematic essay titled *La dynamique qualitative en psychanalyse* (Qualitative dynamics in psychoanalysis) (1994), of which Thom wrote the preface. She writes (Porte 1994, p. 20):

> It is not forbidden to think that in the no man's land that our culture has constituted between the two slopes of the logos, that of number and that of word in general, besides catastrophe theory and semiophysics, a transposed psychoanalysis has its share and its role to play . . . Thus, we give a reason for the "exterritoriality" of psychoanalysis, a theme as hackneyed as it is obscure. "When we have a thought, the meaning of that thought is the form of the underlying neurophysiological process", according to one of the formulae by which Thom has often paraphrased Bernhard Riemann. Thom has taken this statement seriously; Freud's work does not object to it; we propose that both analysts and other researchers take up the program of work that this statement imposes.

Talking about Riemann, let me mention that Thom was also a reader of the latter's philosophical fragments. In his article (Thom 1994), he writes:

> As for myself, it is in reading in Riemann's *Philosophisches Nachlass* the sentence "When we think about thought, the meaning of this thought is nothing but the 'Form' of the underlying physiological process" that I see how the concept of Form can help bridge the gap between the two types of science [Geisteswissenschaften and Naturwissenschaften]. In this light we may reasonably evoke a revival of *Naturphilosophie*.

Porte's reading of Freud using Thom's background brings a fresh point of view on the work of the Viennese Master.

Let me also mention that Thom was aware of the applications of catastrophe theory to psychoanalysis since the beginning of catastrophe theory. We already quoted his comments on Zeeman's article *Topology of the brain* (Zeeman 1965) which gave him an impetus for his ideas on biological modeling; see also Thom's comments in (Thom 2004) (1989). Zeeman's work included the application of catastrophe theory to psychology, ethology and sociology. In the same article, Thom writes that he noticed that in Riemann's *Complete works* edition, there are a few pages where the latter expresses his view on the relation between spirit and matter, and where he claims that one can conceive that if an activity of the brain corresponds to an idea that we think, then the meaning is necessarily defined by the *form* of the corresponding physico-chemical process.

Let me mention, to close this section, that Thom gave a talk at a conference on psychoanalysis titled "L'inconscient et la Science," in which he outlined a possible use in psychoanalysis of his ideas on morphology in the way he applied it in biology and linguistics, see (Thom 1991b).

12 A Metaphysics of Analogy

In the 1970s, Thom started a systematic use of analogies and metaphors in his writings. In fact, his approach to phenomena of science and morphology as taking place in an abstract substrate favored an extensive use of analogy. He declares in the interview *To predict is not to explain* (Thom 1991c, p. 122): "There could be science only if we immerse the real in a controlled virtual. And it is through the extension of the real into a larger virtual that one can study the constraints that define the propagation of the real within that virtual."[32] On a related subject, talking about the notion of "boundary," he declares in another interview: "To reach the limits of what is possible, you have to dream the impossible, and it is really the interface between the possible and the impossible that is important because if we know it, we know exactly the limits of our power" (Nimier).[33]

In the field of analogy, Thom considered himself once again the heir of Aristotle. In a 1976 conference, titled *Le statut épistémologique de la théorie des catastrophes* (Thom 1978d), he writes that "the simple fact of being able to classify analogous situations is a considerable achievement: there has been no theory of analogy since Aristotle." Later, in the interview titled *La théorie des catastrophes* (1992) (Thom 1992d), he declares that catastrophe theory is "a theory of analogy," the first, of such breadth, since Aristotelian logic.

From a strictly mathematical point of view, the word "analogia" is used by Euclid in the *Elements* to denote an equality between two ratios. Thom quotes at several occasions Aristotle's example of analogy saying that old age is to life the same thing as evening is to day, in the form of an equality between two ratios:

$$\frac{\text{old age}}{\text{life}} = \frac{\text{evening}}{\text{day}}.$$

From this follows the metaphor: "old age is the evening of life."[34] In the same passage, Aristotle writes: "The cup is to Bacchus what the shield is to Mars. We shall therefore say: "the shield, cup of Mars," and "the cup, shield of Bacchus."[35]

In his *Esquisse d'une sémiophysique* and in other works, Thom highlighted Aristotle's analogies concerning animals. Let us especially mention an analogy that Aristotle makes in his *Parts of the Animals* (668a10-13), comparing the vascular system of an animal to an irrigation channel in a garden. Thom emphasized this

[32] Il n'y a de science que dans la mesure où l'on plonge le réel dans un virtuel contrôlé. Et c'est par l'extension du réel dans un virtuel plus grand que l'on étudie ensuite les contraintes qui définissent la propagation du réel au sein de ce virtuel.

[33] Pour atteindre les limites du possible, il faut rêver l'impossible, et c'est réellement l'interface entre le possible et l'impossible qui est important parce que si nous le connaissons, nous connaissons exactement les limites de notre pouvoir.

[34] The example is often attributed to Aristotle, but the latter, in a passage of the *Poetics*, quoting this sentence, refers to Empedocles, who said that old age is the sunset of life.

[35] Cf. *Poetics* (Aristotle 1909) 1457b20-21, and *Rhetorics* (Aristotle 1924) 1412b35 and 1413a1-2.

analogy in his 1988 lectures titled *Structure and Function in Aristotelian Biology* (Thom 1990e).[36] Among the other examples of analogies made by Aristotle are the one between the organization of the parts of an animal and the political organization of the city (*Politics*, 1290b25-35), the one saying that sight is to the body what intelligence is to the soul (*Nicomachean Ethics*, 1096b28), the one saying that the soul is to the body what the pilot is to the ship (*De Anima*, 413 a 8-9), the one saying that the scale is to the fish what the feather is to the bird (*History of Animals*, 486b15), and there are many others. Thom, on several occasions, spoke of an analogy between the development of the embryo and that of a Taylor series function. I have commented on other instances of analogy as a method of thinking in the works of Aristotle and Thom in my article (Papadopoulos 2018c).

Thom also talked about Aristotle's theory of analogy in terms of boundary. He writes in (Thom 1991c, p. 75):

> Analogy is not something arbitrary. Analogy, or metaphor, contrary to the common vision that makes it something approximate, fuzzy, appears to me as a strict relation that, in many cases, we can express mathematically, even if this mathematical expression in itself is not interesting in the mental process that makes you consider the analogy.

In the same passage, speaking again of Aristotle's analogy between evening with respect to day, and old age with respect to life, he writes: "The formal structure of this analogy is simply the notion of boundary. You have here a time interval; this interval has an end; one calls 'evening' or 'old age' the tubular neighborhood, if I dare say of the word 'end', and the corresponding catastrophe is, for me, a fold."

Concerning the general role of analogy in science, Thom writes, in his article *The twofold way of catastrophe theory* (Thom 1990a) that this role is very much contested and that it is the object of a vast misunderstanding among professional scientists, most of whom – imbued with a positivist spirit – see it as a source of illusion, claiming that science must be quantitative whereas analogy is a qualitative thought. He reminds the reader that Konrad Lorenz, the famous biologist, in his reception speech of the Nobel Prize, stated that in a certain sense, all analogies are true, by definition. Thom, more precisely, distinguishes two cases of analogies: a "mathematically formalized analogy, associated with an organizing catastrophe," which is always "true, but can be sterile (it can only generate more or less poetic metaphors)," and a "partial" analogy, whose algebraization is incomplete, and he says about the latter: "It is precisely by striving to specify an analogy that one can come across interesting data; it is the incompleteness of the analogy that offers the best possibilities of synthesis. It is only because we accept the risk of error that we can reap new discoveries."

Concerning analogy, I would like also to mention Kurt Gödel, whom Thom often quoted for having shown that a formal system of arithmetic is either inconsistent or incomplete. Gödel made an analogy between this formal side of mathematics and a rigid human society. In a draft letter to David Scurlock, quoted by Pierre Cassou-

[36] A similar agricultural metaphor was made by Plato in the *Timaeus* (Plato 1937) (77c7-8), about blood irrigation in humans.

Noguès in his book *Les Démons de Gödel: Logique et folie* (Gödel's Demons: Logic and Madness) (Cassou-Noguès 2007, p. 164), Gödel writes that one may expect from a society without any freedom at all (i.e., proceeding in everything according to strict rules of "conformity") to be either inconsistent or incomplete in its behavior, i.e., unable to solve certain problems, perhaps of vital importance.[37] He also says that a similar remark can be applied to human beings individually.

Talking about metaphor, I cannot but point out the collection of articles *Mathematics as metaphor* by Manin (2007).

13 Another Return to the Classics

Thom had the particular wish to make topology and the theory of singularities a universal framework which would provide models for all phenomena in the natural and social sciences. Was he convincing? That is another question, but it is a well-known fact that history of knowledge is full of examples of sketches of fundamental theories that took centuries to convince, because they were ahead of their time.

Among the mathematicians who preceded Thom and whose work had a strong philosophical dimension, one can think of Descartes, Leibniz, Euler, Lambert, Riemann, Poincaré, Grassmann, Brouwer, and Weyl, to mention only some of the most famous. All of them considered that the language of mathematics, and in particular that of geometry, goes beyond the mathematical sciences. To mention, while remaining close to Thom's ideas, a famous case of a preeminent mathematician who proposed an idea that eventually was not understood by his contemporaries, one may think of Leibniz's *universal characteristic*, a theory which he intended to develop in reaction to the methods of algebra, which did not satisfy him.[38] The universal characteristic is closely connected with topology in many ways. Leibniz described this field as being more general than that of rigid Euclidean geometry and of Descartes's analytic geometry. He declared that this domain would be purely qualitative and that it was concerned with the study of figures independently of their metrical properties.

Thom refers to Leibniz's universal characteristic in the book *Morphogénèse et imaginaire* (Thom et al. 1978, p. 23):

[37] P. Cassou-Noguès quotes this letter as being part of the Gödel collection held in the library of the Institute of Advanced Study in Princeton. The letter is also quoted by Hao Wang in (Wang 1996, p. 4).

[38] Leibniz used several names for the new field he had in mind: *analysis situs, geometria situs, characteristica situs, characteristica geometrica, analysis geometrica, speciosa situs*, etc.

> In fact, the ultimate ambition of catastrophe theory is to abolish the distinction between mathematical language and natural language which has been rampant in science since the Galilean break. [. . .] A geometrical modeling of ordinary verbal thought will only be of interest if we can, thanks to it, arrive at assertions that the usual logic of natural language cannot provide. This supposes that we are able to:
> 1. Modelize geometrically all the (rigorous) deductions of ordinary thought. In other words: to realize the Leibnizian dream of "universal characteristic".
> 2. Go beyond this.

Leibniz had brought together a number of ideas on this subject and submitted them to Christiaan Huygens, whom he considered as his mentor, but the latter did not find these ideas worth exploring.[39] Leibniz, who had an infinite admiration for his former master, abandoned the project. It is interesting to read here an excerpt from a letter written by Leibniz to Huygens, dated September 8, 1679:

> I am still not happy with Algebra, since it provides neither the shortest ways nor the most beautiful constructions of Geometry. This is why when it comes to that, I think that we need another analysis which is properly geometric or linear, which expresses to us directly *situm*, in the same way as algebra expresses *magnitudinem*. And I think that I have the tools for that, and that we might represent figures and even engines and motion in words, in the same way as algebra represents numbers in magnitude. I am sending you an essay, which seems to me worth considering; there is no other person than you, Sir, who can better judge it, and your opinion will count for me more than many others.

Leibniz sent to Huygens his manuscript titled *Characteristica Geometrica*, dated August 10, 1679. The piece is published in Volume II of Leibniz' *Mathematische Schriften*, edited by Gerhardt (Leibniz 1849), Vol. II, pp. 141–168). and it is also reproduced in Vol. XIII of Huygens' *Collected Works* (Huygens 1899), pp. 219–224). It starts with the words:

> I found some elements of a new characteristic, completely different from Algebra and which will have great advantages for the mental representation in an exact and natural manner, although without figures, of everything that depends on the imagination. Algebra is nothing but the characteristic of undetermined numbers or magnitudes. But it does not directly express place, angles and motions, from which it follows that it is often difficult to reduce, in a computation, what is in a figure, and that it is even more difficult to find geometrical proofs and constructions which are enough practical even when the Algebraic calculations are done. But this new characteristic, based on figures we can see, cannot fail to give at the same time the solution and the construction of geometric proof, in a natural manner, and by analysis, that is, by determined ways. Algebra is obliged to suppose the Elements of Geometry; instead, this characteristic pushes the analysis to the end: if it were completed in the way I conceive it, one could make in characters which will be only letters of the alphabet the description of a machine whatever compound it could be, which would give the means to the mind to know it distinctly and easily with all the parts and even with their use and movement, without using figures or models and without hampering the imagination.

[39] The two men had met for the first time in 1672, in Paris, where Huygens was settled since 1666. Huygens was 17 years older than Leibniz, and for some time he was his private teacher in mathematics.

Leibniz then explains in more detail his vision of this new domain of mathematics, and where it stands with respect to algebra and geometry, giving several examples of a way to denote loci, showing how this allows the expression of statements such as the fact that the intersection of two spherical surfaces is a circle, and the intersection of two planes is a line. The piece ends with the words (Huygens 1899, p. 224):

> I have only one remark to add, namely, that I see that it is possible to extend the characteristic to things which are not subject to imagination. But this is too important and it would lead us too far for me to be able to explain that in a few words.

Huygens was not convinced by Leibniz's project. He responded to him in a letter dated November 22, 1679 ([176] p. 577):

> I have examined carefully what you are asking me regarding your new characteristic, and to be frank with you, I cannot not conceive the fact that you have too much expectations from what you spread on me. Your example of places concerns only realities that were already perfectly known, and the proposition saying that the intersection of a plane and a spherical surface makes the circumference of a circle does not follow clearly. Finally, I cannot see in what way you can apply your characteristic to which you seem you want to reduce all these different matters, like the quadratures, the invention of curves by the properties of tangents, the irrational roots of equations, Diophantus' problems, the shortest and the most beautiful constructions of the geometric problems. And what still appears to me stranger than anything else is the invention and the explanation of machines. I say it to you unsuspiciously: in my opinion this is only wishful thinking, and I need other proofs in order to believe that there could be some reality in what you present. I would nevertheless restrain myself from saying that you are mistaken, knowing the subtlety and the deepness of your mind. I only beg you that the magnificence of the things you are searching won't let you postpone from giving us those which you already found, like this Arithmetic Quadrature you discovered, concerning the roots of the equations beyond the cubical, if you are still satisfied with it.

On continuity in nature, we already mentioned that Thom constantly referred to Aristotle. Talking about Leibniz, we may recall that he declared (Leibniz 1840): "Nothing is done all at once, and it is one of my great and most verified maxims that nature never makes jumps. I called this the law of continuity, when I spoke of it in the news of the republic of letters; and the use of this law is very considerable in Physics," a sentence that reminds us of what Tom declared three centuries later.

The essay that Leibniz sent to Huygens remained practically unknown. But it drew the attention of a few nineteenth-century mathematicians, including Hermann Grassmann (1809–1877), who is considered as the founder of abstract multi-dimensional linear algebra, and, most of all, of a geometric interpretation of this algebra. He was among the first to stress on the importance of Leibniz' *Analysis situs*. We refer the interested reader to the articles (Heath 1917) by Heath and (Echeverrìa 1979) by Echeverrìa.

There exist two recent commented editions of Leibniz's work on the geometric characteristic, both included in doctoral dissertations, the one by J. Echeverrìa (Leibniz 1995), in France, and the other one by de Risi, (de Risi 2007), in Germany.

Like Thom did after him, Grassmann also stressed on the fact that mathematics is the adequate language for understanding the physical world. He formulated a "universal geometric calculus" which was successfully used in the foundations of mechanics, relativity, electrodynamics and quantum mechanics. We refer the reader to the survey article (Hestenes 1996) by D. Hestenes, in which the author gives a glimpse of Grassmann's vision and concludes by the words "An adequate history of geometric calculus remains to be written."

We note in passing that Thom also talked about a universal grammar, see his paper (Thom 1978a).

14 Conclusion

Thom was a singular figure in the history of mathematics, and one of his important contributions was to challenge all dogmas, especially those of science. The fact that he had shifted his focus to philosophy and the consequences of this change were not understood by most of his colleagues: criticisms were voiced here and there, by mathematicians and others, even though the Fields medal assured him an immunity from any dispute of his mathematical talents.

It is not surprising that some colleagues of Thom considered his philosophical reflections as delirium. Some of the criticisms that came from the mathematical community were deeply unfair. In the introduction to his book on catastrophe theory (Arnold 1984), Vladimir Arnold writes (p. viii):

> Neither in 1965 nor later was I ever able to understand a word of Thom's own talks on catastrophes. He once described them to me (in French?) as "bla-bla-bla," when I asked him, in the early seventies, whether he had proved his announcements. Even today, I don't know whether Thom's statements on the topological classification of bifurcations in gradient dynamical systems depending on four parameters are true. [...] Nor am I able to discuss other, more philosophical or poetical declarations by Thom, formulated so as to make it impossible to decide whether they are true or false (in a manner typical rather of medieval science before Descartes or (the) Bacon(s)).[40]

Thom did not waver, but deep down, the reactions to his ideas hurt him. He wrote in *La science malgré tout* (Science despite everything) (Thom 1975a):

[40]It is fair to add that several years later, Arnold changed his mind concerning Thom. In an interview published in avril 1997 (Liu 1997), he writes: "I am deeply indebted to Thom, whose singularity seminar at the Institut des Hautes Études Scientifiques, which I frequented throughout the year 1965, profoundly changed my mathematical universe. I was always delighted by the way in which Thom discussed mathematics, using sentences obviously having no strict logical meaning at all. While I was never able to completely free myself from the straitjacket of logic, I was forever poisoned by the dream of the irresponsible mathematical speculation with no exact meaning."

> It used to be fashionable—and probably still is—in scientific circles, to rave about philosophy. And yet, who could deny that the only really important problems for man are philosophical problems? But philosophical problems, being the most important ones, are also the most difficult ones; in this field, to show originality is very difficult, a fortiori to discover a new truth. This is why the society, very wisely, has given up subsidizing research on philosophical subjects, where the profit is too uncertain, to devote its efforts to scientific research, where, thank God, it is not necessary to be a genius to do a "useful work".

Did the community of philosophers understand Thom? In some sense, the answer is simple: unlike the situation in mathematics, there is no philosophical community. In his article *Leaving mathematics for philosophy*, (Thom 1992c), Thom explains that in philosophy, things are not as simple as in mathematics: there are schools, cliques, etc.

Regardless of his involvement in philosophy, Thom had a personal view on mathematics and on mathematicians and why we do mathematics, which he expressed sometimes in a very metaphorical mode. In his paper *De l'icône au symbole. Esquisse d'une théorie du symbolisme* (From icon to symbol. A sketch of a theory of symbolism) (Thom 1973), he writes:

> I would like to see the mathematician as a perpetual newborn babbling in front of nature; only those who know how to listen to Mother Nature's answer will later manage to open a dialogue with her, and to master a new language. The others only babble, buzzing in the void — *bombinans in vacuo*. And where, you may ask, could the mathematician hear the answer of nature? The voice of reality is in the sense of the symbol.

Manin is among the mathematicians who understood Thom's approach since the beginning. In his contribution to Kyoto's ICM (1990), he writes (Manin 1990):

> [. . .] What is relevant is the imbalance between various basic values which is produced by the emphasis on proof. Proof itself is a derivative of the notion of "truth." There are a lot of values besides truth, among them "activities," "beauty" and "understanding," which are essential in the high school teaching and later. Neglecting precisely these values, a teacher (or a university professor) tragically fails. Unfortunately, this also is not universally recognized. A sociological analysis of the controversies around Catastrophe Theory of René Thom shows that exactly the shift of orientation from formal proof to understanding provoked such a sharp criticism. But of course, Catastrophe Theory is one of the developed mathematical metaphors and should only be judged as such.

In any case, Thom felt out of step with the mathematical milieu of his time, which was rather very monolithic. He writes (Thom 1980, p. 29):

> I never really thought of myself as a mathematician. In fact, a mathematician must have, in my opinion, a taste for difficulty, for beautiful, rich and deep structures. I do not have that taste at all. The ultra-refined structures that fascinate my colleagues—Lie groups, simple finite groups, etc., in short, all these kinds of mathematical mythologies—have never really interested me. On the other hand, I like things that move, flexible things that I can transform to my liking. I prefer the field of mathematics where one does not really know what he is doing! This is the reason why I consider mathematics today with a certain detachment, and I

> cannot say whether there is currently a strictly mathematical problem for which I have a deep interest.

Thom declared several times that even though he became a mathematician by accident, mathematics brought him great satisfaction. In the interview (Thom 1991c), he says: "Really, when one has found a theorem in his lifetime, he can tell that he participated in a certain form of immortality, whatever he did. An illusion perhaps, but among all the fictitious immortalities by which we are deluded, this is still one of the most solid" (Thom 1991c, p. 73)]. In the article *La science malgré tout* (Thom 1975a), he writes: "I know only one really difficult science: mathematics."

Appendix: Jean Cavaillès and Albert Lautman

Let me say a few words on the two philosophers of science, Jean Cavaillès (1903–1944) and Albert Lautman (1908–1944) to whom Thom was attracted as a young student.

Cavaillès is the author of an important philosophical corpus on the foundations of mathematics in which the stress is on a dynamical evolution of these foundations. Among the multitude of philosophical schools of the first half of the twentieth century, Cavaillès was situated between Hilbert's formalism and Brouwer's intuitivism, a trend that he used to call "modified formalism." He was close to the mathematician Émile Borel, one of the French representatives of the "semi-intuitionist" current. As a matter of fact, in 1940, Cavaillès wrote an authoritative synthesis of Borel's theory of the quantification of chance (Cavailles 1940), which constitutes the latter's point of view on the philosophy of probability theory expressed in Vol. IV of his *Traité du calcul des probabilités et de ses applications* (Borel 1939). The volume is titled *Valeur pratique et philosophie des probabilités*.

Cavaillès taught at the École Normale Supérieure before Thom entered there. His philosophical work, which was in part the result of a close collaboration with Emmy Neother, had a non-negligible impact on the mathematical research done at the École.

Lautman had been Cavaillès's student at the École Normale. In 1937, he defended a doctoral dissertation, in two parts, the first one titled *Essai sur les notions de structure et d'existence en mathématiques* (Essay on the notions of structure and existence in mathematics), and the second one, *Essai sur l'unité des sciences mathématiques dans leur développement actuel* (Essay on the unity of the mathematical sciences in their present development).[41] Following the path of Cavaillès

[41] The French doctoral system (doctoral d'état) required the defense of two dissertations. The first one was the main thesis, and the subject of the second one was proposed by the jury of the doctorate, a few months before the defense. Its preparation was supposed to take only a few months (usually 3 to 4).

(and before him, that of Poincaré), Lautman considered that both the formalist and the intuitionist movements were a failure. He was an advocate of structuralism in the tradition of Bourbaki. He was a promoter of the concept of unity of mathematics, see the collection of articles (Lautman 1977).

Cavailles and Lautman found the sources of their theories in the recent developments in mathematics and physics (notably quantum physics). They both wondered about the role and the consequences of the various movements of thought that had appeared at the end of the nineteenth century on the philosophy of mathematics (conventionalism, logicism, constructivism, formalism, etc.). Even if they diverged on some points, and in particular on the organization of mathematics as a system of thought, they both considered that the philosophy of mathematics must necessarily be at the center of any metaphysical theory, as it was already for Plato, Heidegger and other philosophers. Their work is an embodiment of this approach. Both Cavailles and Lautman had close relations with mathematicians of the Bourbaki group such as Cartan, Chevalley, Dieudonné, Ehresmann, and Weil, and they were very much interested in Boubaki's project of writing complete treatises on the foundations of several topics in mathematics.

During the Second World War, Lautman et Cavaillès joined the resistance to the German occupation of France. They were both shot by the Nazis in 1944. The first was 36 years old and the second 40.

The French Society of Philosophy devoted its session of February 4, 1939 to the discussion of Cavaillès and Lautman's works. Several mathematicians, including Henri Cartan, Paul Dubreuil, Paul Lévy, Maurice Fréchet, Charles Ehresmann, and Claude Chabauty, were present at that session. A report on this session was published after the liberation of France, in the Bulletin de la Société française de philosophie (La pensée mathématique 1946) (1946). Thom may have been present at this debate, but being still too young, his name is not mentioned in the Annals.

Abstract

Proofs are central to mathematical practice in large part due to the heuristic role that some of them play. Not only do they help establish a result, but often provide new avenues of mathematical research. Jody Azzouni has argued that underlying the practice of creating mathematical proofs there is a very specific norm: to each proof there should be a corresponding algorithmic derivation, a derivation in an algorithmic system. Here a framework is provided to classify and assess mathematical proofs. It is argued that there is a plurality of kinds of proofs in mathematics and a plurality of roles these proofs play. In the end, mathematical practice is far less unified in this respect than it may seem to be.

For helpful discussions, I would like to thank Joe Auslander, Jody Azzouni, Alan Baker, Peter Caws, Michael Clarkson, Mark Colyvan, Kenny Easwaran, Ed Erwin, Michele Friend, Elaine Landry, Marc Lange, Peter Lewis, Catarina Dutilh Novaes, Andrea Pedeferri, Eric Saidel, Harvey Siegel, Susan Vineberg, Charlotte Werndl, and Tadeusz Zawidzki.

1 Introduction

Mathematical proofs have multiple functions in mathematics. They are, of course, primarily used to establish the relevant theorems. But it would be inadequate to conclude that this exhausts the role they play. Some proofs also provide explanation – an understanding of why a particular theorem holds, rather than simply establishing that it holds. These proofs often involve some form of construction or, in some cases, some visualizable aspects as an integral part of it. Proofs also develop ways of refining concepts, typically in the context of alleged counterexamples that need to be taken into account and avoided. Concept refinement in mathematical theorem proving is something that Imre Lakatos insightfully highlighted in his work (see Lakatos 1976, 1978). Other proofs connect different parts of mathematics that were thought of as being unconnected. Andrew Wiles' proof of Fermat's last theorem is often presented as providing that sort of unification (Wiles 1995). Some accounts of mathematical explanation connect the explanatory role of mathematical theorizing with this unificatory role; but not all do. In the end, different types of proof play different roles in mathematics.

In what follows, these issues are explored and a framework to classify proofs and assess proofs is offered. It is argued that there is a plurality of kinds of proofs in mathematics and that mathematical practice is far less unified in this respect than it has been suggested. Jody Azzouni argues that, underlying the practice of creating mathematical proofs, we find the norm to the effect that there should always be a corresponding algorithmic derivation, a derivation in an algorithmic system (Azzouni 1994, 2004, 2006). In many instances this is the case, but it need not always be so. Some informal proofs do not seem to be guided or constrained in any way by an underlying algorithmic derivation. As will become clear, there is far more plurality in mathematical proofs than meets the eye. In particular, there is not a single answer to the question of what a mathematical proof really proves. In different contexts, different kinds of answers are offered, with different goals and distinctive norms. It is pluralism all the way down.

I will start by considering some difficulties inherent in Azzouni's formulation of the relevant norm. I will then offer a taxonomy of different kinds of proofs, their roles and the norms they are expected to satisfy.

2 Norms in Mathematics

Azzouni (1994, 2004, 2006) argues that from the beginning of the twentieth century on, the norm of mathematical proofs requires that they correspond to algorithmic mathematical derivations. (I will call this the *algorithmic norm*.) Before the last century, he notes, the norm was simply to avoid gaps in the proofs. The new norm, which was made possible by the development of mathematical logic, is used to explain a significant aspect of mathematical practice: the stability of mathematical theorems. These theorems are preserved over time and turn out not to need to be revised when mechanical (algorithmic, automated) proofs of the relevant theorems are developed and ultimately implemented.

But why is the algorithmic norm generally not acknowledged as a norm in mathematical practice? This is because of its tacit character: mathematicians do not explicitly articulate the norm as such. The exception, of course, is found among computer scientists and those who work in automated theorem proving, since for them the search for algorithmic derivations is indeed the norm. It is telling that the norm is then explicitly acknowledged, articulated and implemented by the community. There is no tacit character in this case.

There are, however, several difficulties with this way of conceptualizing this norm of mathematics. First, a methodological problem emerges. It is unclear how a norm that is not explicitly acknowledged as such can actually play the role of a norm. It could be simply an accident that the various mathematicians have conformed to the norm rather than have actively shaped their practice by following it. The same practice can be structured and understood as emerging from a very different norm. If, in turn, that norm is explicitly acknowledged, it is more likely that it has played (or could have played) the role of a norm in configuring and structuring the practice. Moreover, a tacit norm is one for which it is difficult to provide evidence, since in order for one to establish that a certain norm is operative in the practice, one needs to determine to what extent the relevant practitioners acknowledge it and have acted in accordance to it. In fact, as I will argue below, this is precisely what has happened in the case of mathematics: when norms are active, they are acknowledged as such.

Second, can the stability of mathematical theorems be explained without the algorithmic norm? As will become clear, there are additional norms (each corresponding to the kind of proofs in question) that can be invoked as having played a role in shaping the relevant community. For these norms are not tacit and have been explicitly acknowledged by mathematicians. It is far more reasonable to countenance them as being norms than the tacit algorithmic norm.

Finally, even if the algorithmic norm had been explicitly formulated, it is unclear that it really explains the stability of mathematical theorems. For, as will become clear, the diversity of styles of mathematical proofs (that is, the various kinds of mathematical proofs we will discuss) challenges that a single norm that fits properly only a very narrow range of proofs could account for all the other kinds of proofs and their roles within mathematical practice. And since the algorithmic norm is tacit, Azzouni's account is unable to rule out that other norms are actually in place and structuring the practice.

I assume with Azzouni that some norm is active in mathematical practice. The alternative would be to consider that practice as entirely unregulated and unstructured. If this were the case, it would be very difficult to explain the stability of mathematics. So, I agree with Azzouni that some norm is needed, but I think he gave a disproportionate role to one particular norm, whereas there are many others in place.

For these reasons it is better to conceptualize mathematical practice in terms of other norms: those that are explicitly voiced by the relevant mathematical community. As will become clear, there is a plurality of such norms, each associated with a different kind of mathematical proof.

3 Kinds of Mathematical Proofs and Their Roles

3.1 Kinds of Mathematical Proofs

There are two main kinds of mathematical proofs: informal and formal proofs. Formal proofs are those familiar from formalized languages. Informal proofs comprise the bulk of proofs in mathematics. Among the informal proofs there are: descriptive (or language-based) proofs and diagrammatic proofs. Diagrammatic proofs are those that are implemented via a diagram rather than a linguistic description.[1] Descriptive proofs are the usual proofs mathematicians devise to establish theorems. They are the most common resource employed in mathematical practice and the central and distinctive feature of mathematical activity. As will become clear, proofs are valued for the information they provide about certain mathematical objects,[2] for allowing for conceptual refinement, and for the development of new techniques and the possibility of connecting fields that were not seen as being related before.

Among descriptive proofs, we find: truly informal proofs, pre-formal proofs, and post-formal proofs. Truly informal proofs need not correspond to any formalized counterpart. A significant portion of informal proofs is of this kind. Pre-formal proofs are regular informal proofs that could, with some work, be transformed into a formal one. Finally, post-formal proofs are proofs that emerge after a formal proof is provided. Some belong to the truly informal category, whereas others are pre-formal.[3]

[1] A discussion of diagrams as full-blown proofs can be found, e.g., in Brown (1999) and Azzouni (2013) (see also references therein). Nelson (1993) provides a number of examples of diagrammatic proofs.

[2] Whether these objects exist (or not) independently of their description by suitable comprehension principles is an additional issue, largely of philosophical interest, but not of much mathematical relevance.

[3] I am invoking here a distinction between pre-formal and post-formal proofs that Lakatos once introduced (1978), p. 61). He identified three kinds of mathematical proofs: pre-formal proofs, formal proofs, and post-formal proofs, where pre-formal and post-formal proofs belong to the

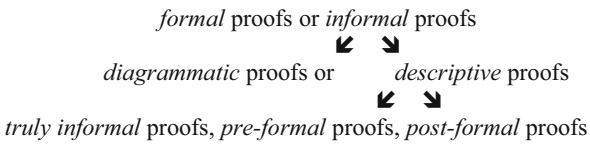

Fig. 1 Kinds of Mathematical Proofs

Schematically, we have the figure above (Fig. 1):

3.2 Roles Played by Mathematical Proofs

This characterization of kinds of proofs does not indicate the roles played by proofs. This motivates a different categorization in which proofs are grouped by their *function* rather than by their *kind*. The functional characterization goes as follows:

(a) *Justificatory proofs*: These proofs have only one purpose: to establish that a certain result holds given the assumptions in the theorem. And that is exactly what they do – nothing more, nothing less. Simple computational proofs are of this kind.
(b) *Explanatory proofs*: These proofs not only establish the result, but also help one understand why the result holds. When following the argument presented in the proof, the reader can see why the result is the case. These proofs are particularly valuable given that they provide additional information that illuminates the topic at hand. Constructive proofs are often of this kind.
(c) *Unification-inducing proofs*: These proofs bring together different areas or sub-fields of mathematics, or rely on methods that are commonly used in one area and apply them to a different area. They are also valuable for the increased information they provide.
(d) *Concept-refining proofs*: These proofs involve the refinement of concepts in order to adjust the target theorem, which only holds for the proper specification of the concepts involved. This is another feature that makes proofs particularly valuable – they are a significant source of conceptual innovation and refinement.

Typically, formal proofs only satisfy the first role. Formal proofs are not explanatory, do not induce unification nor do they lead to concept refinement. They are stripped down to the bare bones. The only trait they exhibit is the capacity to establish inferential links from one line in the proof to the next, with nothing by way of illumination, suggestive links to new sub-fields, introduction of new techniques, or daring ideas. They lack precisely those features that make mathematical

category of informal proofs. His classification did not explicitly accommodate diagrammatic proofs, although these proofs would clearly be informal. Some of the examples that Lakatos discussed involve diagrams, but only as aids rather than full-blown proofs. So a broader characterization than the one he offered is needed.

proofs so valuable to mathematicians. In contrast, rigorous informal proofs, those that are commonly found in mathematical practice, can satisfy all of the roles above. Not every proof will exemplify all the four roles, but the fact that they are capable of doing more than just justifying the result contributes significantly to their relevance.

4 Justificatory Proofs

Mathematical proofs, are traditionally conceptualized in terms of deductive, formal arguments. The standard used in these conceptualizations is the one offered by mathematical logic, in which the steps in a proof follow explicitly given syntactic patterns, and the meaning of the expressions, terms or sentences in the proof are ignored. Of course, a semantic counterpart to these expressions can be given, and if the logic is complete, there is a perfect match between the sentences that can be (syntactically) derived from the principles in question, and the sentences that follow logically (semantically) from such principles.

It turns out, however, that preciously little of this formal approach to mathematical proofs is of much help when we try to make sense of mathematical practice (Azzouni 2006). First, the meaning of mathematical expressions is central in actual mathematical proofs – i.e., those proofs that are actually used in mathematical practice. Often, the validity of the proof will turn on the interpretation of the concepts that are used in the proof. A purely formal argument is hardly ever used.

The mismatch between formal and semantic arguments should not be downplayed. Several significant results in mathematics only hold for logics that are incomplete, such as second-order logic: they allow for true results not to be derivable in the relevant system. A mathematical result that illustrates this situation is the categoricity of real analysis – the fact that every model of real analysis is isomorphic. This result only holds if it is assumed that the underlying logic is second-order,[4] and hence incomplete. Thus, we have here an illustration of the fact that the mismatch between semantic and syntactic components of mathematical proofs not only should be expected, but it is also central to mathematical practice.

More generally, the mismatch between a logical conception of proof and the standards for proof in mathematical practice has a long tradition. Consider, as a simple illustration, that the proofs in Euclid's *Elements* could not be faithfully formulated in syllogistic form. Interestingly enough, the fact that the most important form of logic in Greek antiquity could not be used to formulate and assess the actual proofs offered in the most important companion of geometry of its time was not considered to be a problem for either discipline. The mismatch has been with us for a long time.

There are, of course, areas in mathematics where formal proofs are the main goal: computer-generated proofs and automated theorem proving are significant

[4] For first-order theories, given that the Löwenheim-Skolem theorem holds, there will be non-standard models of real analysis, and the categoricity no longer holds.

developments in computer science. These branches of mathematics could not be developed and implemented without formal proofs. But, as far as mathematical practice is concerned, they are the exception rather than the norm.

5 Explanatory Proofs

Let us consider three very different examples of mathematical proofs:

(i) The Löwenheim-Skolem theorem: This is a model-theoretic argument that involves the construction of various kinds of models for first-order theories.
(ii) Proofs by mathematical induction: This is a structural argument, in the sense that the structure of the relevant objects – in this case, the natural numbers – is taken into account in order to implement the proof. It is due to the way in which natural numbers are built that such proofs can be run.
(iii) The intermediary-value theorem: This is a straightforward feature of continuous functions in the real line, and the proof explores this fact.

Do the proofs of these theorems *explain* the results besides establishing them? The answer depends on the conditions under which mathematical proofs explain the relevant results. There are different conceptions of explanation and different ways of characterizing what makes a mathematical proof explanatory (Mancosu (2011) provides a good survey, which I follow here). Some views insist that an explanatory proof should identify some intrinsic, characterizing feature of the objects under study. As Mark Steiner notes: "an explanatory proof depends on a characterizing property of something mentioned in the theorem" (1978, p. 147; italics omitted). This property characterizes a certain entity or structure, and the proof makes it clear that the result relies on that property.

But here we have a difficulty. Proofs by mathematical induction are typically not thought of as being explanatory (although there is some controversy about this issue; see Lange (2009) and Baker (2010). However, pace Steiner, proofs by mathematical induction seem to be obvious examples of explanatory proofs via a characterizing property, since they rely on the characterizing property of natural numbers. But are they really explanatory? Moreover, neither the Löwenheim-Skolem nor the intermediary-value theorems are established via a characterizing property.

Other views of mathematical explanation insist on the unifying role that some proofs provide (Kitcher 1981, 1989; Friedman 1974). On this model, the goal is to identify "the best tradeoff between minimizing the number of patterns of derivation employed and maximizing the number of conclusions generated" (Kitcher 1989, p. 432). This seems to suggest that finite axiomatizations of certain theories would be preferred as being more explanatory, since such axiomatizations minimize the number of patterns of derivation (the axioms) while maximizing the number of conclusions that are obtained. But is it clear why Zermelo-Fraenkel set theory is less explanatory than von Neumann-Bernays-Gödel, just because the latter is finitely axiomatizable and the former is not? It is also unclear whether any of the proofs of

the theorems mentioned above, (i)–(iii), are explanatory at all. None of them involve such unifying role.

Another possibility is to use the pragmatics of explanation as a framework to account for mathematical explanations. On this model, an explanation is an answer to a why question, and it involves three components (van Fraassen 1980, Chapter 5): a *topic* (what the explanation is about), a *contrast class* (the alternatives with respect to which the question is specified), and a *relevance relation* (that involves what would count as an acceptable answer to the question). In the case of the intermediary-value theorem, why does a continuous function that has negative and positive values also need to have a value equal to zero (rather than no value at all)? One could say that if we were to deny the statement of the theorem, a contradiction would be derived. This answers the question as to why the theorem holds. But clearly this would not be an explanation specific enough for the theorem in question: it holds for every mathematical theorem! How can the theorems mentioned above be illuminated? More generally, there are concerns as to the adequacy of using the theory of why questions in mathematics (Sandborg 1998).

Some diagrammatic proofs can also be explanatory in that they allow one to experience visually how the theorem in question can be true. Consider the following theorem:

Theorem: $1 + 2 + 3 + \ldots + n = n^2/2 + n/2$.

Its usual proof is given by mathematical induction. But it can also be given via a diagram (Brown 2005, p. 64) (Fig. 2):

Although the diagram only illustrates the case $n = 5$, it is clear that it can be extended without difficulty for any natural number. The problem, however, is that the explanatory nature of this proof only holds for a limited class of objects (diagrammatic proofs). And even these proofs may not be explanatory, since one cannot generalize from the diagrams.

As a result, we find here a significant pluralism about mathematical explanations (Mancosu 2011). It is unlikely that a single notion of explanation is capable of accommodating the variety of instances of explanation in mathematical practice. But no proposal invokes anything remotely near the algorithmic norm as part of what makes a proof explanatory.

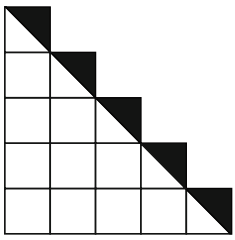

Fig. 2 Diagrammatic Proof

For those who think that mathematical theorems are necessarily true, the idea of an explanatory proof may sound bizarre. What else could be required from a proof but the fact that it establishes the target result, which holds no matter what? But the fact that mathematicians often acknowledge that some proofs are better than others on the grounds that they allow one to understand why the result holds (rather than only that it does hold) is an indication that the distinction between explanatory and non-explanatory proofs is acknowledged.

I do not actually think that mathematical theorems are, strictly speaking, necessary. The results hold given certain comprehension principles that characterize a certain domain and given the underlying logic. If either of them changes, the result in question may no longer hold. This view, which admittedly is not in the majority, accommodates very naturally the distinction between explanatory and non-explanatory proofs. Even though a certain theorem holds – given the comprehension principles and the underlying logic – there may be different strategies of establishing that this is the case. Some of these strategies may be more illuminating or informative than others, thus leading to explanatory proofs rather than non-explanatory ones. The algorithmic norm is not part of this process.

6 Unification-Inducing Proofs

Consider the case of Skolem's theorem regarding the relativity of set-theoretic notions: a countable model can satisfy the first-order sentence that states that there are uncountably many objects (such as uncountably many real numbers). When Thoralf Skolem first introduced his result, it was offered as an attempt to refute the adequacy of set theory as a suitable foundational framework for mathematics (Skolem 1922/1976). With the relativity of set-theoretic notions, Skolem thought, it should be clear that set theory fails to yield the uniqueness that would be expected in a suitable foundation for mathematics. In the end, instead of generating a *reductio* of the use of set-theoretic notions in mathematics, Skolem's result was simply incorporated as a significant feature of set theory. The relativity of set-theoretic notions to the model in which they are expressed is a central aspect of the theory – and it is a feature that has a significant heuristic role. This feature allows set theory to be used so fruitfully in mathematics, offering a rich framework to represent various results.[5]

There are, of course, cases in which proofs can play multiple roles, e.g., being both unification inducing and explanatory. In his examination of the role of a new set-theoretic axiom, Kurt Gödel notes:

[5] Despite set theory's powerful expressive resources, alternative frameworks have been developed as well. In some of them, sets do not feature at all. The use of category theory or second-order mereology to formulate mathematical theories provides obvious examples. No sets need to be invoked there.

> even in case it (a new set-theoretic axiom) had no intrinsic necessity at all, a (probable) decision about its truth is possible also in another way, namely, inductively by studying its 'success', that is, its fruitfulness in consequences demonstrable without the new axiom, whose proofs by means of the new axiom, however, are considerably simpler and easier to discover, and make it possible to condense into one proof many different proofs. The axioms for the system of real numbers, rejected by the intuitionists, have in this sense been verified to some extent owing to the fact that analytical number theory frequently allows us to prove number theoretical theorems which can subsequently be verified by elementary methods. (Gödel 1964, p. 265)

We find here the idea that a new axiom may be heuristically so fruitful that it can "condense into one proof many different proofs". In this case, we obtain unification at the level of proofs rather than at the level of theories or methods. This form of unification also provides additional justification to the relevant results if the proofs obtained using the new axiom can also be obtained with weaker – and less contentious – axioms.

Gödel also is reported as having drawn an interesting distinction between foundational and explanatory principles in mathematics (see Lakatos 1978):

> The role of alleged 'foundations' is rather comparable to the function discharged, in physical theory, by explanatory hypotheses (. . .). The so-called logical or set-theoretical 'foundation' for number-theory or of any other well established mathematical theory, is explanatory, rather than really foundational, exactly as in physics where the actual function of axioms is to *explain* the phenomena described by the theorems of this system rather than to provide a genuine 'foundation' for such theorems. (Mehlberg 1962, p. 86)

In this passage, we find the contrast between a foundational and an explanatory role of axioms. The foundational role is implicitly being questioned, since it seems to require a commitment to the certainty of the principles in the foundation, something that is ultimately incompatible with the empirically-oriented, and ultimately contingent, explanatory role. The sense of explanation in this context seems to be something akin to making sense of how the relevant results emerge (or could be derived) from the principles in question. The revisability of physical principles is thus transferred and assimilated to mathematics. The unification provided by the relevant axioms also brings some contingency, and there is very little role for the algorithmic norm in this context.

7 Concept-Refining Proofs

Lakatos has highlighted the importance of conceptual shifts in mathematics (Lakatos 1976, 1978). He also emphasized the significance of proof analysis as a tool in the formulation and development of mathematical proofs. This approach tends to downplay the importance of a purely formal approach to the understanding of mathematical reasoning, emphasizing the analysis of concepts, conceptual shifts, and conceptual refinement.

On this approach, mathematical results are relativized: they hold in virtue of certain principles that are assumed to hold in a given context, and fail otherwise. Consider, for example, the issue as to whether every set can be well ordered. The answer, ultimately, is: it depends. If the axiom of choice is assumed, then the result does hold, since the latter follows from the axiom. If the axiom does not hold, however, the result fails. Part of the process of proof analysis involves the identification of hidden premises in mathematical arguments, and in particular in attempts to prove certain results. This is particularly clear in the case of Ernst Zermelo's original axiomatization of set theory, and the resulting uncovering of the axiom of choice (Zermelo 1904/1976, 1908/1976).

Formal proofs cannot be the ultimate goal (or the norm) of mathematics. For even after a formal proof is established, informal proofs about the resulting proof need to be addressed. This is illustrated, for instance, by the existence of nonstandard models of arithmetic or analysis. It is realized that results that were proved formally depend on the model that was used to establish them: new results emerge in nonstandard models, but proofs about such models are typically done informally (see Lakatos 1978, p. 69). The resulting interplay between formal and informal proofs does not fit very well with a single algorithmic norm.

8 Conclusion: Pluralism about Proofs

The considerations above suggest that proofs play multiple roles in mathematical practice: they are sources of evidence (justificatory role); they explain why a result holds (explanatory role); they unify diverse domains (unification-inducing role); and they lead to the development and refinement of new concepts (concept-refining role).

Formal proofs are unable to deliver three out of four of these roles. It is thus unclear how the search for algorithmic systems should be the norm for mathematical proofs, as Azzouni has suggested. In the end, a norm that flies on the face of some much mathematical activity does not seem adequate. Mathematical proofs are far more varied and diverse than such a norm would recommend. As a result, a more pluralist view seems to provide a better alternative.

Abstract

David Hilbert sought to secure the epistemic foundations of mathematics by providing consistency proofs of axiomatized mathematical theories from within the *finite standpoint*. This standpoint requires concrete constructions without reference to completed infinities. In 1938, Gerhardt Gentzen proved the

consistency of first-order Peano Arithmetic relying on the well-ordering of certain ordinal notations. This was thought by Gentzen and Paul Bernays to be finitistically acceptable. However, a finitistically acceptable proof of the relevant well-ordering was not available until Gaisi Takeuti's proof in 1978. Beginning with the proposition that Takeuti's proof conforms to the finite standpoint, this chapter explores the limits of a finitism based on the methods of Gentzen and Takeuti. It is argued that the upper limit is the Feferman-Schütte ordinal, and thus that finitism may be extended to strong subsystems of second-order arithmetic-systems strong enough to provide a theory of the ordinals for which Gentzen employed notations.

Consistency · Constructive mathematics · Finitism · Gentzen · Hilbert's program · Ordinal notations · Predicativism · Proof theory · Takeuti · Transfinite induction

1 Introduction

The goal of Hilbert's Program, roughly speaking, was to develop epistemically secure foundations for classical mathematics by means of constructive, finitist consistency proofs for as much of mathematics as possible. A plausible candidate for such a proof is Gentzen's (second) proof of the consistency of pure number theory (first-order arithmetic with full induction). However, Gentzen's proof involves induction on ordinal notations less than ε_0: a move that is potentially controversial depending upon what the bounds of finitist acceptability are taken to be. Yet, there is no consensus with respect to the limits of the finitist standpoint. At the lower end is the standpoint advanced by W. W. Tait (1981, 2002) and others, who argue that Primitive Recursive Arithmetic (PRA) exhausts finitism. Remarks from Hilbert, Bernays, and others suggest that finitism extends beyond PRA: that induction up to certain transfinite ordinals is finitistically acceptable. Unless already considered finitistically acceptable, a constructive finitist proof of the well-ordering of ordinal notations up to a transfinite ordinal is necessary and sufficient for determining that induction up to that ordinal is finitistically acceptable. Relative to this standpoint, it remains unclear how far the bounds of finitism will extend. This thread is pursued below, and drawing upon Gaisi Takeuti's (1987) work, a new potential upper limit for the bounds of finitist acceptability is identified.

This chapter begins with a brief introduction to the historical background of the finitist standpoint: an outline of its origins in Hilbert's Program and its intended epistemic role with respect to consistency proofs. The discussion then turns to Gentzen's proof theoretic work and his proof of the consistency of pure number theory. Establishing that Genzen's consistency proof is finitistically acceptable is the motivation behind Takeuti's (1987) proof of the well-ordering of ordinal notations (in Cantor normal form) less than ε_0. That proof is outlined, and the key methods and

operations that the proof involves are introduced. Takeuti claims that all of those methods and operations are acceptable according to what he calls the "Hilbert-Gentzen finitist standpoint." Yet, it is straightforward to illustrate how the methods and operations used in Takeuti's well-ordering proof can be amended to demonstrate the well-ordering of ordinal notations (given using Veblen functions and symbols for zero and ordinal addition) for ordinals less than Γ_0. Accordingly, if Takeuti's claims about his proof's finitistic acceptability are correct, the Hilbert-Gentzen finitist standpoint can be extended to the *Takeuti-Veblen* standpoint: induction up to Γ_0 is finitistically acceptable. This chapter concludes with a brief examination of the philosophical and mathematical significance of the Takeuti-Veblen standpoint.

2 Historical Background: Hilbert and Gentzen

The late nineteenth and early twentieth centuries saw monumental developments in mathematical logic, especially set theory. But the foundations of those discoveries were shaken by the discovery of "antinomies" like Russell's paradox and Cantor's paradox. These paradoxes motivated the development of programs in the philosophy of mathematics aimed at avoiding inconsistencies and securing the epistemic foundations of mathematics. Russell's logicism and use of the theory of types, the intuitionism of Brouwer and Heyting, the predicativism of Kroeneker and Poincaré, and the finitism of Hilbert and Bernays have all been developed and defended in some form throughout the twentieth century and into the twenty-first. (See the first section of Benacerraf and Putnam (1983) for a historical introduction, and Shapiro (2005) and Lindström et al. (2009) for more recent developments.)

2.1 Hilbert's Program

At its most general, Hilbert's Program involves three components:

1. The axiomatization of mathematical theories.
2. The concept of finitistic mathematics or the finite standpoint as epistemically privileged and secure.
3. A search for finitisically acceptable consistency proofs for axiomatized mathematical theories.

Remark 1 Hilbert's formalism was also an important part of his philosophical and mathematical work at the time, and while that aspect of his work is closely tied to finitism and constructive mathematics, it will be less important in what follows.

Hilbert's axiomatization of Euclidean geometry (Hilbert 1899) was an early important success for the first component, while an axiomatization of arithmetic was most famously developed by Guiseppe Peano (1889) and Richard Dedekind

Dedekind (1888). The axiomatization of set theory was under active development in the early twentieth century, as well (though that project is arguably ongoing).

The second component – finitism – is the core of the program and will be discussed in detail in this section and below. However, given an acceptance of component 2, it is easy to see that component 3 – finitisically acceptable consistency proofs for mathematical theories – will provide an epistemically secure foundation for those theories. If we can prove that a theory is consistent using tools that we already know to be acceptable and secure, we can then be sure that that theory will not lead us astray.

Remark 2 It should be noted that a defense of component 2 will not be undertaken herein; the starting point for this discussion is at least the weak position that some version of finitism can plausibly do the epistemic work needed to motivate the search for finitisically acceptable consistency proofs. That said, the proofs of Gentzen and Takeuti, and their implications, are of significant theoretical interest outside of a commitment to finitism or other constructivist philosophies of mathematics.

As the reader may already have noticed, however, there is a potential problem for Hilbert's Program that needs addressing: Gödel's Theorems. In 1931, Kurt Gödel proved that for any sufficiently strong mathematical theory Γ, any theory that can prove the consistency of Γ must be *strictly* stronger than Γ. This means that the finitist cannot proceed simply by proving the consistency of stronger and stronger theories based on already established consistency results. To prove the consistency of Peano Arithmetic, the finitist cannot rely on, say, PRA, or even on an equiconsistency result; they must use more powerful resources that nevertheless conform to the finite standpoint. Such resources were arguably developed by Gerhard Gentzen in the 1930s. It is the acceptability of those resources and the consequences of their finististic *bona fides* that are the concern of much of the rest of this chapter. But first, a brief discussion of Gentzen's proof theory is in order.

2.2 Gentzen's Proof Theory

Gerhard Gentzen can rightly be seen as the father of modern proof theory, developing the techniques that formed the foundation of later developments. He is perhaps most famous for his proof of the cut-elimination theorem which says that for any proof in the sequent calculus using the cut rule, there is an analogous proof without cut. This is key to the consistency proof discussed below. Gentzen also made significant developments in both intuitionistic and classical sequent and natural deduction calculi, including the normalization theorem for the latter, which is closely related to the cut elimination theorem (see Mancosu et al. (2021) for an introduction to Gentzen's proof theory, and Gentzen (1969) for translations of his important works). While the details of Gentzen's contributions to proof theory (besides the proof discussed in the following section) are far beyond the scope of this chapter, it is important to note his influence on later proof theorists, including Takeuti, as well as

the recent resurgence of interest in his work (see Kanckos 2011, and related publications).

3 Gentzen's Proof

Gentzen published three consistency proofs for what was called, at the time, pure arithmetic-first order Peano Arithmetic (PA). The strategy of the first two proofs is similar, and indeed Akiyoshi and Takahashi (2013) show that the second proof is a special case of the first. Nevertheless, it was, and still is, the second proof, published in 1938, that has been the most influential. It is the second proof that underlies the importance of Takeuti's well-ordering proof.

3.1 Ordinal Notations

A theorem due to Georg Cantor (1897) says that every ordinal can be written as a sum of 0 and exponents of ω, i.e.,

$$\alpha = \omega^{\beta_1} + \omega^{\beta_2} + \omega^{\beta_3} + \omega^{\beta_4} + \ldots$$

α, β ordinals, the βs either in this form, or 0s, and

$$\beta_1 \geq \beta_2 \geq \beta_3 \geq \ldots$$

Since Gentzen's proof requires only ordinals less the ε_0 and ε_0 is the first ordinal such that $\omega^{\alpha} = \alpha\,(\text{i.e.}\omega^{\varepsilon_0} = \varepsilon_0)$, it is guaranteed that $\alpha > \omega^{\beta_i}$ for all $i > 1$, and $\alpha = \omega^{\beta_1}$ only in the case where the $\omega^{\beta_{i>i}}$ are empty.

An ordinal written in this notation is in *Cantor normal form*. For simplicity, ω^0 can be written as 1, $\omega^0 + \omega^0$ as 2, and so on for the natural numbers. The further condition that any "+0" terms are deleted guarantees that each notation is unique.

The *natural sum* of two ordinals, α and μ, written $\alpha\#\mu$, is a (possibly) new ordinal in Cantor normal form constructed by interleaving the monomials – terms of the form ω^{β_i} – so that the β's are decreasing. For example, given the following ordinal notations, ξ and γ

$$\xi = \omega^{\omega^{\omega^3}} + \omega^{\omega+\omega} + \omega^2 + 2$$

and

$$\gamma = \omega^{\omega^{\omega^{\omega}}} + \omega^{\omega+\omega} + \omega$$

their natural sum, $\xi\#\gamma$, is the following ordinal notation:

$$\xi\#\gamma = \omega^{\omega^{\omega^{\omega}}} + \omega^{\omega^{\omega^{3}}} + \omega^{\omega+\omega} + \omega^{\omega+\omega} + \omega^2 + \omega + 2$$

It is the well-ordering of these notations that Gentzen used for the transfinite induction steps in his proof. Thus, for Gentzen's consistency proof to be truly finitistic, the well-ordering of these ordinal notations must be established from within the finite standpoint. This is Takeuti's essential contribution.

3.2 The Consistency of Pure Number Theory

The general strategy of Gentzen's consistency proof is as follows. Take an arbitrary proof of the empty sequent in the sequent calculus, with arithmetical initial sequents, and the inference rule for (full) arithmetical induction (i.e., first-order Peano Arithmetic formulated in the sequent calculus) and show that such a proof cannot exist.

Remark 3 The empty sequent is a contradiction, so its derivation implies the inconsistency of the theory in which it has been derived. Importantly, though, the empty sequent, unlike any other contradictions, contains no logical connectives.

To show that no such proof exists, the end part of the proof, defined as the largest segment of the proof looking "up" from the end-sequent, that contains only structural rules (including inductions), is pushed all the way to the top of the proof. This results in a proof containing no introduction or elimination rules. This is possible, because the end-sequent contains no connectives, so any complex formulae will have to have been removed by a cut at some point.

Inductions are reduced to sequences of cuts, and cuts on complex formulae are reduced to cuts on atomic formulae. This is all done to a "regular" proof, in a principled manner, but the details need not concern us here. (See Mancosu et al. 2021, for a detailed introduction to Gentzen's proof.)

Remark 4 A regular proof is one in which all of the noneigen variables have been replaced with 0 s and the eigenvariables have been replaced with appropriate arithmetic terms.

The key to the proof, and the part relevant here, is showing that the procedure terminates. Gentzen does this by assigning ordinal notations to each sequent and inference, and showing that each reduction step decreases the ordinal notation assigned to the end-sequent of the proof. Although the procedures for assigning ordinal notations to inductions and cuts are quite complex, the operations involved are just the stacking of finitely many $\boldsymbol{\omega}$ exponents, the taking of natural sums, and ordinary, arithmetical subtractions.

What is left is to show that the reduction procedure terminates, or, in other words, to show that the ordinal notations in Cantor normal form less than ε_0 are well ordered.

Of course, from a nonfinitist perspective, it is immediately clear that the ordinal notations are well-ordered: Each notation represents a unique ordinal less than ε_0, which is itself an ordinal. This entails that the ordinal notations are well-ordered by the set membership relation, "$\in$." But this requires reasoning about completed infinities, which the finitist eschews.

4 Takeuti's Proof

Takeuti proposes a concrete method for demonstrating that the ordinals less than ε_0 are well-ordered. His demonstration consists in applications of a series of concrete methods, called "eliminators." Eliminators are methods for taking any given strictly decreasing sequence of ordinals and constructing new strictly decreasing sequence of ordinals such that if the latter contains no infinitely descending chains, neither does the former. Using eliminators, Takeuti gives a demonstration that the ordinals $<\varepsilon_0$ are well-ordered.

Remark 5 Takeuti uses the term "concrete" in much the same way the term "constructive" might be used. While constructive mathematics or concrete proof procedures apply outside the finitist domain, in the context of Takeuti's proof, it can be safely assumed that "concrete" implies "conforms, in Takeuti's view, to the finite standpoint."

With the uncontroversial starting assumption that the natural numbers (and thus $\boldsymbol{\omega}$) are well-ordered, the basic idea is to separate parts of ordinal notations that have already been proven to be well-ordered, to show that the larger ordinal notations are well-ordered. This allows the well-ordering of larger and larger ordinal notations to be established.

An example from Takeuti's proof is provided below, but a toy example may be helpful first.

4.1 Toy Example: Proving the Well-Ordering of Positive Numerals

Take as your goal, rather than the well-ordering of notations for transfinite ordinals, the well-ordering of the notations for natural numbers – the positive numerals. Assume, as a starting point, that you know, perhaps from counting your fingers, that the numerals 1–10 are well ordered. The next step is to establish the well-ordering of the numerals 11–20. Write these as $10 + 10{,}10 + 9{,}10 + 8 \ldots 10 + 1$.

Remark 6 Note that the notations are written in *descending* order, so that we can more easily see that there are no infinitely descending chains of notations.

Obviously $10 = 10$, so, given the usual definition of addition, we can immediately see that the notations for natural numbers less than 20 are well-ordered. Now that we

know that, we can use essentially the same procedure to get us to 100 in 8 more steps.

The next set of steps gets us to 1000. Create a descending sequence as follows $100 + 100{,}100 + 90 + 9100 + 90 + 8...100 + 80 + 9...100(+0) +1$.

We can see that the second two terms ($90 + 8$, etc.) are the same as our notations for natural numbers less than 100, so we only need to deal with the sequence $100 + 100{,}100 + 90{,}100 + 80...100 + 10$, and then use our earlier procedure for the notations in between. But we can rewrite our sequence as $100 + 10{\cdot}10{,}100 + 10{\cdot}9...100 + 10{\cdot}1$. Since $100 = 100$ and $10 = 10$, by our initial assumption, the notations for natural numbers less than 1000 are well-ordered.

We can continue on like this, adding another layer for each power of 10, and using our previous results to show that our base-10 notations for natural numbers less than $\boldsymbol{\omega}$ are well-ordered.

Because Takeuti is working with transfinite ordinals with a lexigraphic ordering, his proof is significantly more complex, but the idea is the same: Separate the notations into parts that are equal, and parts we already know are well-ordered.

The following subsection is a reconstruction of the first step of Takeuti's proof, adapted from Darnell and Thomas-Bolduc (2018, §4) and Darnell and ThomasBolduc (2022, §3).

4.2 The 1-Eliminator

Takeuti begins his proof by supposing that the natural numbers are well-ordered (Takeuti 1987, pp. 92–93). Takeuti's *eliminators* capitalize on the well-ordering of the natural numbers and enable him to demonstrate that, strictly decreasing sequences of ordinals beginning with any ordinal, $<\varepsilon_0$ must be finite.

5 Terms and the 1-Eliminator

(Adapted from Takeuti 1987, p. 93.) The first eliminator Takeuti introduces the *1-eliminator*. The 1-eliminator is a concrete method for constructing a *1-sequence*, S_0' from a given decreasing sequence of ordinals, S_0, such that the first ordinal in S_0' is the *1-major part* of the first ordinal in S_0 and if S_0' is finite, then S_0 is finite. Takeuti explains these terms by way of an illustration:

Consider a strictly decreasing sequence of ordinals,

$$(S_0) \quad a_0 > a_1 > \ldots$$

such that each a_i in S_0 is written in Cantor normal form and a_0 is not a natural number. A 1-eliminator is a method for taking S_0 and producing a decreasing 1-sequence:

$$(S'_0) \quad b_0 > b_1 > \ldots$$

that satisfies the following conditions:

(CI) $b_0 = a_0^*$ (i.e., b_0 is the 1-major part of a_0; see below).
(CII) If S'_0 is finite, then S_0 is finite.

Takeuti calls the part of a_i that does not contain k_i the *1-major part* of a_i:

$$\underbrace{\omega^{\mu^i_1} + \omega^{\mu^i_2} + \ldots + \omega^{\mu^i_n}}_{1-\text{major part of } a_i} + k_i$$

where each $\mu^i_m > 0, \mu^i_{m-1} > \mu^i_m$ and k_i is a natural number (the i's are just indices). Let the 1-major part of a_i be written as: a'_i. Takeuti calls a sequence that consists of just the 1-major parts of each a_i in S_0 a *1-sequence*.

The 1-eliminator is shown to satisfy (CI) as follows. By definition, each ordinal in S_0 is identical with its 1-major part plus a given natural number. That is, $a_i = a'_i + k_i$ for all a_i in.

S_0. Hence, S_0 can be written as:

$$a'_0 + k_0 > a'_1 + k_1 > \ldots$$

applying a 1-eliminator to this sequence still produces the 1-sequence, S'_0. Now, take some finite part of S'_0, say the sequence:

$$b_0 > b_1 > \ldots > b_m$$

where, $b_0 = a'_0$ and $b_m = a'_i$ (for some i). So, either $a'_i = a'_{i+1} = \ldots = a'_{i+p}$ (for some p) and a_{i+p} is the last term in S_0 (the last term with a 1-major part), or $a'_{i+p} > a'_{i+p+1}$. If the former is the case, then stop. If the latter is the case, then make $b_{m+1} = a'_{i+p+1}$ and repeat. If one arrives at a sequence of a'_i's such that $b_m = a'_i$ and $a'_i = a'_{i+1} = \ldots = a'_{i+p} = \ldots$, it follows that S_0 must be finite. Since S_0 is a strictly decreasing sequence, $a'_i = a'_{i+1} = \ldots = a'_{i+p} = \ldots$ entails that $k_i > k_{i+1} > \ldots > k_{i+p} > \ldots$ Given the well-ordering of the natural numbers, the latter sequence must be finite. Hence, S_0 must be finite. Given the definition of S'_0 (i.e., a strictly decreasing 1-sequence constructed from S_0), if S'_0 is finite, then there is a last term, b_m, in S'_0 such that $b_m = a'_i$ and $a'_i = a'_{i+1} = \ldots = a'_{i+p} = \ldots$ Therefore, if S'_0 is finite, so is S_0.

6 Proving a Well-Order with the 1-Eliminator

(Adapted from Takeuti 1987, p. 93.) Takeuti uses the 1-eliminator to show that all decreasing sequences of ordinals that begin with an ordinal $<\omega^2$ must be finite. Let

$$(S_1) \quad a_0 > a_1 > \ldots$$

be a strictly decreasing sequence of ordinals such that $a_0 < \omega^2$. Applying a 1-eliminator to S_1 enables the construction of the 1-sequence:

$$\left(S_1^*\right) \quad b_0 > b_1 > \ldots$$

such that S_1^* satisfies conditions (CI) and (CII) and where $a_0 \geq b_0$. Since $a_0 < \omega^2$, $b_0 < \omega^2$. It follows that each ordinal b_i in S_1^* has the form, $\omega \cdot k_i$ (where k_i is a natural number). Accordingly, since a_0 is not a natural number, each b_i in S_1^* will be of the form, $\omega \cdot k_i$ (where k_i is a natural number). Hence, S_1^* can be written as:

$$\omega \cdot k_0 > \omega \cdot k_1 > \ldots$$

It must then be the case that $k_0 > k_1 > \ldots$, which must be finite. Therefore, $b_0 > b_1 > \ldots$ must be finite. Since S_1^* satisfies (CI) and (CII), S_1 must be finite. S_1 was arbitrary, so this result generalizes: Any decreasing sequence of ordinals which begins with an ordinal $<\omega^2$ must be finite.

The above procedure nicely illustrates Takeuti's strategy throughout his proof. He continues with this strategy such that with each new eliminator, combined with the well-ordering of the sequences of ordinals already established, he can show that sequences of ordinals with higher and higher limits must be well-ordered, ending with a demonstration of the well-ordering of the ordinals $<\varepsilon_0$.

7 Defining Finitism After Hilbert

As might be expected, there has been a lack of consensus as to the limits of the finite standpoint. One way to think about this is in terms of an upper bound on the strength of mathematical theories that can be properly thought of as finitist. Although there have been attempts to delineate the upper bound of the finite standpoint, including a new proposal put forth below, there is no consensus as to what exactly should count as finitistic mathematics. Indeed, after the publication of Gödel's second incompleteness theorem, it is unclear what Hilbert and Bernays considered to be the limits of finitism. There are indications that they considered finitism to extend beyond Primitive Recursive Arithmetic, and it seems Bernays considered Gentzen's second consistency proof to be finitisically acceptable (see Hilbert and Bernays (1939, p. 340–348), Zach (1998), and Darnell and Thomas-Bolduc (2018)).

Below, one thread in the development of finitism flowing through the work of Gentzen and Takeuti is taken up and developed. This thread focuses on constructive proof-theoretical tools, and the limits those tools put on the development of finitisically acceptable consistency proofs. Before delving into that, however, a brief look at the lower bound of finitism will be instructive.

7.1 More than PRA?

Primitive recursive arithmetic (PRA) – a relatively weak theory containing all of the primitive recursive functions, including those for 0, +, ×, and the successor function, as well as the quantifier-free induction scheme – is solidly within the realm of finitism. As the value of a primitive recursive function can always be found in finitely many steps, there is no threat of impermissible infinite reasoning. And because the induction schema is quantifier free, there is no risk of quantifying over completed infinite totalities.

Tait (1981, 2002) argues that finitism is completely exhausted by PRA, though he explicitly distances himself from the epistemological underpinning of Hilbert's finitism. As Stenlund (2009) argues, the purely technical aspects and epistemological goals of finitism cannot be so easily separated.

Given that the development of finistism is motivated, in large part, by a desire to establish epistemic security for a useful portion of mathematics, it is best not to be guided too strictly by intuitive notions of what counts as "finitistic." To do so would beg the question against the finitist. Nevertheless, PRA is a good lower bound for which mathematical theories conform to the finite standpoint (Darnell and Thomas-Bolduc 2018).

7.2 The Hilbert-Gentzen Standpoint

Bernays himself acknowledges that Gentzen's proofs were finitiscally acceptable:

> During the printing of this report the proof for the consistency of the full number theoretic formalism has been presented by G. Gentzen, using a method that conforms to the fundamental demands of the finite standpoint. (Bernays 1935, final paragraph)

It is likely, then, that Bernays had some familiarity with Gentzen (1943), wherein Gentzen discusses the finitistic acceptability of the induction on notations for transfinite ordinals. Gentzen tentatively concludes that his methods are finitistically acceptable, as did Bernays.

Thus, even before Takeuti published his well-ordering proof, there was a conception of finitism that included Gentzen's methods. This is the basis of what Takeuti calls the "Hilbert-Gentzen" finitist standpoint (Takeuti (1987, p. 101), Feferman (2005, p. 601)).

More specifically, there are two core components to the Hilbert-Gentzen standpoint, as discussed by Takeuti. The first is the limited use of transfinite induction, such as that employed in Gentzen's proof (Takeuti 1987, p. 88). The second is that it involves "'Gedankenxperimente' only on clearly defined operations applied to some concretely given figures and on some clearly defined inferences concerning these operations" (Takeuti 1987, p. 97).

The Hilbert-Gentzen standpoint, then, is roughly the standpoint that the construction of finitisically acceptable consistency proofs may involve limited use of

transfinite induction on concretely given figures, and *Gendankenexperimente* on finitistically acceptable operations and inferences. While this may seem vague, it circumscribes the methodology available under this standpoint. It also has the unsurprising consequence of encompassing Gentzen's proof via Takeuti's proof.

Takeuti's proof solidifies Gentzen's use of ordinal notations, and by extension PA, as finsitically acceptable (see Darnell and Thomas-Bolduc 2018, for an argument for this claim). However, Takeuti mentions that his proof could be extended beyond ε_0 (Takeuti 1987, p 97). He does not provide a proof and concentrated his later efforts on ordinal diagrams (see Takeuti (1957, 1958)). Ordinal diagrams are an interesting and complex ordinal notation system, but it will suffice to note that, despite significant efforts, it has not been shown that ordinal diagrams are "concrete" (and therefore finitisically acceptable).

8 The Takeuti-Veblen Finitist Standpoint

Taking Takeuti's assertion that his method of eliminators can be extended beyond ε_0, it is natural to ask just how far those methods can be taken. Since ε_0 is the first ordinal such that $\varepsilon_0 = \omega^{\varepsilon_0}$, new tools are needed. However, given those tools, as described below, Takeuti's method can be extended to *concretely* show that notations for ordinals less that Γ_0, the Feferman-Schütte ordinal, can be well-ordered. This opens up the possibility of finitism encompassing vastly more powerful mathematics.

The finite standpoint so extended might then be called the Takeuti-Veblen standpoint. The significance of this extended standpoint will be elaborated on below; however, its feasibility must first be established.

8.1 The Limits of the Extended Program

Takeuti mentions that the method of eliminators can be extended beyond ε_0, but does not conjecture as to an upper limit. In order to prove the well-ordering of ordinal notations up to some limit $\lambda > \omega$ (we write α_λ for the limit ordinal with notation λ) viz. the method of eliminators, the following must be satisfied.

(N1) For every ordinal α such that $0 \neq \alpha < \alpha_\lambda$, there is a unique constructive notation for α.
(N2) For every ordinal notation $\boldsymbol{\theta} < \lambda$, there is a concrete (or constructive) method for obtaining $\boldsymbol{\theta}$.
(N3) For every ordinal α such that $1 < \alpha < \alpha_\lambda$, the notation for α can be given using finitely many notations for ordinals $<\alpha$, "0," and appropriate symbols for ordinal addition, multiplication, or exponentiation.

Remark 7 (N1)–(N3) are mutually reinforcing. Each is needed for the purposes of: (i) maintaining the arithmetic relations (symbolized) between ordinal notations that

are required for using Takeuti's eliminators (some of which – the use of addition, multiplication, etc. – are highlighted in previous sections), and (ii) ensuring that it is possible to construct new eliminators from eliminators that have been concretely given (for details, see (Takeuti 1987, p. 96) and (Darnell and Thomas-Bolduc 2022, §3.4)).

Feferman (Feferman 1964) and Schütte (Schütte 1965) (independently) established that a unique constructive notation for every ordinal $<\Gamma_0$ can be given using Veblen functions (introduced by Veblen in (Veblen 1908)), and symbols for zero and ordinal addition (a detailed exposition of this result is given in Schütte (1977)). Their work satisfies (N1)–(N3) for ordinals $<\Gamma_0$; thus, the method of eliminators can be used to show the well-ordering of the relevant notations for ordinals $<\Gamma_0$.

Remark 8 For brevity, a complete proof of this claim is not provided herein. Instead, a sketch of a representative part of its demonstration is provided. The complete proof is now being prepared and will appear elsewhere.

Following Feferman (1964, p. 15), we can construct unique notations for ordinals $0 < \alpha < \Gamma_0$.

Remark 9 The notation employed below is a modification Feferman's Feferman (1964) notation in order to make it more obvious how Takeuti's eliminator method can be amended and extended beyond ε_0.

For ordinal notations ξ, θ, and γ, and limit notation λ, we write $\phi(\gamma, \theta)$ for the normal functions (i.e., continuous and strictly increasing functions) from ordinals to ordinals in the following transfinite sequence of normal functions,

$$\phi(\gamma, 0) = \omega^{\gamma};$$

$$\phi(\gamma, \theta + 1) = \text{the } \gamma^{\text{th}} \text{ solution } \xi \text{ of } \phi(\xi, \theta) = \xi;$$

$$\phi(\gamma, \lambda) = \text{the } \gamma^{\text{th}} \text{ solution } \xi \text{ of } \phi(\xi, \theta) = \xi \text{ for all } \theta < \lambda.$$

The functions generated in this way make up the *Veblen hierarchy*. Using the above (and the previously introduced symbols 0 and +), we can construct ordinal notations in a variation of Cantor normal form (hereafter, VCNF). To illustrate, ω^0 is written as $\phi(0,0)$ in VCNF, $\omega^0 + \omega^0$ is written as $\phi\ (0,0) + \phi\ (0,0)$ in VCNF, and so on (continuing to use numerals as notations for ordinals $< \boldsymbol{\omega}$). We write the natural sum of ordinal notations in VCNF analogously to before. For example, given the ordinal notations, ξ and γ in VCNF,

$$\xi = \phi(\phi(\phi(3,\ \ 0),\ 0), 0) + \phi(\phi(1,\ 0) + \phi(1,\ 0), 0) + \phi(2, 0) + 2$$

(in Cantor normal form, ξ is written, $\omega^{\omega^{\omega^3}} + \omega^{\omega+\omega} + \omega^2 + 2$) and

$$\gamma = \phi(\phi(\phi(\phi(1, \quad 0), \quad 0), \quad 0), 0) + \phi(\phi(1, \quad 0) + \phi(1, \quad 0), 0) + \phi(1, 0)$$

(in Cantor normal form, γ is written, $\omega^{\omega^{\omega^\omega}} + \omega^{\omega+\omega} + \omega$) their natural sum, $\xi \# \gamma$, is the following ordinal notation in VCNF:

$$\begin{aligned} \xi\#\gamma = \quad & \phi(\phi(\phi(\phi(1, \quad 0), \quad 0), \quad 0), 0) + \phi(\phi(\phi(3, \quad 0), \quad 0), 0) \\ & +\phi(\phi(1, \quad 0) + \phi(1, \quad 0), 0) + \phi(\phi(1, \quad 0) + \phi(1, \quad 0), 0) \\ & +\phi(2, 0) + \phi(1, 0) + 2 \end{aligned}$$

(in Cantor normal form, $\xi \# \gamma$ is written, $\omega^{\omega^{\omega^\omega}} + \omega^{\omega^{\omega^3}} + \omega^{\omega+\omega} + \omega^{\omega+\omega} + \omega^2 + \omega + 2$).

Remark 10 In Miller (1976, §6), Miller uses notations similar to VCNF to give a characterization of Takeuti's ordinal diagrams. The relationship between ordinal diagrams and Schütte's notations is examined in Levitz (1970).

Takeuti's method of eliminators can be straightforwardly amended to show the well-ordering of ordinal notations in VCNF for ordinals $<\varepsilon_0$ (i.e., for notations $\theta < \phi(0, 1)$). It is also not difficult to extend the amended method of eliminators to show the well-ordering of ordinal notations in VCNF for ordinals $<\Gamma_0$. For example, in order to show that all decreasing sequences of ordinal notations that begin with notations $\phi(0, 1) < \theta < \phi(\phi(0, 1) + 1, 0)$ (i.e., VCNF notations for ordinals α where, $\varepsilon_0 < \alpha < \omega^{\varepsilon_0+1}$) are finite, Takeuti might use a 1^1_0-eliminator.

Associated with 1^1_0-eliminators would be analogues of the concepts of a 1-major part and a 1-sequence. In particular,

Definition 1 For any ordinal $\alpha_i < \Gamma_0$ with VCNF notation a_i, the 1^1_0-*major part* of a_i is the part of its VCNF that contains no monomial $<\phi(\phi(0, 1), 0)$ (i.e., no monomial $< \omega^{\varepsilon_0}$).

For every ordinal $\alpha_i < \Gamma_0$ with VCNF notation a_i, we write a_i^{1*} for the 1^1_0-major part of a_i.

Definition 2 For any strictly decreasing sequence of VCNF notations $a_0 > a_1 > \ldots$, the sequence $a_0^{1*} > a_1^{1*} \ldots$ is the 1^1_0-*sequence* corresponding to $a_0 > a_1 > \ldots$, just in case for any $i \geq 0$, every a_i^{1*} in $a_0^{1*} > a_1^{1*} > \ldots$ is the 1^1_0-major part of a_i in $a_0 > a_1 > \ldots$.

For any strictly decreasing sequence of ordinals S_j, we write S_j^{1*} for the 1^1_0-sequence corresponding to S_j. For any strictly decreasing sequence of ordinals S, we say that S is a 1^1_0-sequence just in case there is a decreasing sequence of ordinals S_j such that $S = S_j^{1*}$ (i.e., S is the 1^1_0-sequence corresponding to S_j).

Definition 3 A 1_0^1-*eliminator* is a (concrete) method for constructing a 1_0^1-sequence S_j^{1*} from a (concretely) given strictly decreasing sequence of ordinal notations S_j, such that the first ordinal notation in S_j^{1*} is the 1_0^1-major part of the first ordinal notation in S_j, and if S_j^{1*} is finite, then S_j is also finite.

To illustrate, let

$$\left(S_0^1\right) \qquad a_0 > a_1 > \ldots.$$

be a strictly decreasing sequence such that, for any $i \geq 0$, every a_i in S_0^1 is of the form $a_i^{1*} + c_i$, and

$$\underbrace{\phi\left(\mu_1^i, 0\right) \cdot k_i^1 + \ldots + \phi\left(\mu_{m_i}^i, 0\right) \cdot k_i^m}_{a_i^{1*} = 1_0^1 - \text{major part of } a_i} + \underbrace{\phi\left(\mu_{m_i+p_i}^i, 0\right) \cdot k_i^{m+p} + \ldots + \phi\left(\mu_{m_i+p_i+l_i}^i, 0\right) \cdot k_i^{m+p+l}}_{c_i}$$

only if

$$\phi\left(\mu_1^i, 0\right) \cdot k_i^1 \geq \phi(\phi(0,\ 1), 0), \ldots, \phi\left(\mu_{m_i}^i, 0\right) \cdot k_i^m \geq \phi(\phi(0,\ 1), 0)$$

And

$$\begin{aligned} \phi\left(\mu_{m_i+p_i}^i, 0\right) \cdot k_i^{m+p} &< \phi(\phi(0,\ 1), 0), \ldots, \phi\left(\mu_{m_i+p_i+l_i}^i, 0\right) \cdot k_i^{m+p+l} \\ &< \phi(\phi(0,\ 1), 0). \end{aligned}$$

The 1_0^1-eliminator is a method that takes S_0^1 and concretely produces a 1_0^1-sequence,

$$\left(S_0^{1*}\right) \qquad b_0 > b_1 > \ldots$$

such that S_0^{1*} satisfies each of the following conditions:

$\left(\text{CI}_0^1\right)$ $b_0 = a_0^{1*}$ (i.e., b_0 is the 1_0^1- major part of a_0).
$\left(\text{CII}_0^1\right)$ If S_0^{1*} is finite, then (it can be concretely shown that) S_0^1 is finite.

An analogue of the procedure used earlier to show that the 1-sequence S_0' generated by the 1-eliminator (applied to S_0) is finite and satisfies (CI) can be used to show that S_0^{1*} is finite and satisfies $\left(\text{CI}_0^1\right)$. Once adequately justified by previous results (and buttressed by *Gedankenexperimente*), an appropriate analogue of

Takeuti's (1987, p. 94) induction hypothesis (e.g., *Any descending sequence of ordinal notations $d_0 > d_1 > \ldots$, with $d_0 < \phi(\phi(0, 1) + 1, 0)$ is finite.*) can then be used to demonstrate that S_0^{1*} satisfies $\left(\mathrm{CII}_0^1\right)$.

Remark 11 For Takeuti, adherence to the Hilbert-Gentzen finitist standpoint permits omitting the actual execution of a step in his proof when that step of the proof or its relevant consequence(s) can be known viz. *Gedankenexperimente* restricted to "only on clearly defined operations applied to some concretely given figures and on some clearly defined inferences concerning [those] operations" (Takeuti 1975, p. 97).

The 1_0^1-eliminator can be used to demonstrate the well-ordering of ordinal notations (in VCNF) for ordinals $\alpha < \omega^{\varepsilon_0+1}$. Assume we have demonstrated the well-ordering of VCNF notations for ordinals $\alpha < \varepsilon_0$. Let

$$\left(S_e^1\right) \quad a_0 > a_1 > \ldots.$$

be a strictly decreasing sequence such that, $\phi(0, 1) < a_0 < \phi(\phi(0, 1) + 1, 0)$ (i.e., a_0 is the VCNF notation for some ordinal α such that $\omega^{\varepsilon_0} < \alpha < \omega^{\varepsilon_0+1}$). Applying a 1_0^1-eliminator to S_e^1 generates the 1_0^1-sequence:

$$\left(S_e^{1*}\right) \quad b_0 > b_1 > \ldots$$

such that S_e^{1*} satisfies each of $\left(\mathrm{CI}_0^1\right)$ and $\left(\mathrm{CII}_0^1\right)$ and where $a_0 \geq b_0$. By supposition, $a_0 < \phi(\phi(0, 1) + 1, 0)$, and so $b_0 < \phi(\phi(0, 1) + 1, 0)$. By Definitions 1 and 2, for any $i > 0$, every b_i in S_e^{1*} is of the form $\phi(0, 1) \cdot k_i$ (where k_i is a natural number). Hence, S_e^{1*} can be written as:

$$\phi(0, 1) \cdot k_0 > \phi(0, 1) \cdot k_1 > \ldots$$

Thus, $k_0 > k_1 > \ldots$ The natural numbers are well-ordered, and so $k_0 > k_1 > \ldots$ is finite. Hence, S_e^{1*} is finite. Hence, by Definition 3, S_e^1 is finite. Therefore, ordinal notations $< \omega^{\varepsilon_0+1}$ are well-ordered.

Appropriate analogues of the steps in Takeuti's Takeuti (1987) well-ordering proof can be used to show that an eliminator can be concretely given for every ordinal notation in VCNF for every ordinal $<\Gamma_0$. Once this is shown, a procedure like the one just sketched above can be used to show the well-ordering of ordinal notations in VCNF for ordinals $<\Gamma_0$.

8.2 The Importance of Takeuti-Veblen Standpoint

Γ_0 is the proof-theoretic ordinal of the subsystem of second-order arithmetic called ATR_0 – Arithmetic Transfinite Recursion. While that certainly does not sound finitistic, it means that given a suitable axiomatization and proof system, ATR_0, or

a system of equal consistency strength, ought to be provably consistent within the Takeuti-Veblen finite standpoint.

This would be a significant result for a number of philosophical and mathematical reasons. Most generally and most basically, this result could be seen as a vindication of Hilbert's Program. If consistency proofs for strong subsystems of second-order arithmetic are available with the finite standpoint, Hilbert's Program can be seen as a bridled success a century later.

More specifically, the system ATR_0 can prove, or is equivalent to, a number of important theorems, including from descriptive set theory (see Simpson 2009, C V for details and proofs). One result of particular interest is that "the set existence axioms of ATR_0 are indispensable for a decent theory of countable ordinals" (Simpson 2009, p. 195). In other words, the Takeuti-Veblen standpoint allows for the development of a theory of countable transfinite ordinals. This is a particularly pleasing result, as it entails that ordinals themselves that Gentzen used notations for in his consistency proof are actually available within the finite standpoint.

On the other hand, from a certain philosophical perspective, these results might lead to an opposite conclusion. For some finitists, such strong results might be proof that something has gone wrong and the Hilbert-Gentzen standpoint should be rejected. The apparent availability of such intuitively nonfinitistic resources may be taken as evidence that PRA is the *upper* as well as lower bound of finitism. However, such a position would require finding fault with Takeuti's proofs, likely focusing on the use of *Gedankenexperimente*.

The last consequence to be discussed here is less certain and has to do with the conjectured ordinal upper bound of the Takeuti-Veblen standpoint, $\Gamma_0 \cdot \Gamma_0$, which is arguably a natural stopping point because it is thought to also be the limit of predicative arithmetical theories.

Remark 12 Predicativism, very roughly, is the philosophico-mathematical idea that to secure the epistemic foundations of mathematics, we must avoid definitions where the definiens range over the entities in the definiendum. The idea is to ban circularity in definitions and axioms and thereby avoid paradoxes – like Russell's paradox – arising from impredicative axioms like naive set comprehension.

That finitism and predicativism might coincide in such a way would be a remarkable convergence of the two most significant strands of classical constructive mathematics (see Kreisel 1958; Feferman 2005; Simpson 2009, for discussion of the relationships between finitism and predicativism). This coincidence is little more than conjecture at this point; however, both its proof and dis-proof would be interesting results. If the two programs were shown to coincide in their upper limits, that would be powerful evidence of a rich and useful theory of constructive classical mathematics, and potentially greatly extend the tools available for the development of constructive mathematics.

On the other hand, a proof or argument that the upper limits of predicativism and finitism do not coincide would reveal important information about both programs and their relationship. The obvious way to go about this would be to determine upper

bounds from within each respective system – finitism using finititist means, a predicativism using predicativist means. These would be important results in their own rights. However, if a comparison were carried out that conformed to the strictures of *both* programs, the formal nature of the divergence would provide insight into classical constructive mathematics that would shed light on the nature of the epistemic issues undergirding its development. In either case, because of the constructive nature of the proofs, specific information would be forthcoming beyond the existence or not of the coincidence.

Mathematician's Reflections on Practice and Working Philosophy of Mathematics

Athanase Papadopoulos

Introduction to *Mathematicians' Reflections on Practice and Working Philosophy of Mathematics*

Athanase Papadopoulos

Abstract

This is the introduction to the section "*Mathematicians' Reflections on Practice and Working Philosophy of Mathematics*" of the *Handbook of the History and Philosophy of Mathematical Practice*. It essentially consists of descriptions of the various chapters that constitute this section.

Keywords

Plato's philosophy · Indivisible lines · L. E. J. Brouwer · Mathematical practice as philosophy · Anthyphairesis · Pavel Florensky · Mathematics in education · Intuitionism · Russian Golden Age · Russian Silver Age

AMS Classification

00A30 · 01A60 · 01A20 · 00A30 · 03A10 · 03A05 · 97E20

The second section of this Handbook, titled "Mathematicians' Reflections on Practice and Working Philosophy of Mathematics," consists of 10 chapters. All are written by mathematicians involved in philosophical questions, and they are concerned with the relation between mathematical and philosophical practices. The interested reader, whether he is knowledgeable or not in philosophy, will find a large spectrum of ideas and points of view on how mathematics and philosophy together can help understanding the world of ideas.

B. Sriraman (ed.), *Handbook of the History and Philosophy of Mathematical Practice*,
https://doi.org/10.1007/978-3-031-40846-5_128

The subject of the first three chapters in this section is Plato's philosophy. The first two are written by Stelios Negrepontis and the third one by Stelios Negrepontis and Demetra Kalisperi. I would like to emphasize that Plato was a mathematician; probably not in the modern sense of the word, since no theorem can be attributed to him, but because all his thinking was oriented towards mathematics. He was fully engaged in questions such as what is mathematics, why and how can we acquire mathematical knowledge, what is the nature of mathematical ideas and of the various mathematical objects, what kind of mathematics is suitable for education and for the well-being of the soul, etc. It is also worth remembering that Plato was the founder of a school, *the Academy*, probably the most important school that ever existed, and that in that school, Plato was essentially teaching mathematics. I like to recall a sentence by Aristoxenus of Tarentum, the famous fourth century BC music theorist, about Plato with whom he was quite familiar. In his *Harmonics*, reporting on the teachings of Plato, Aristoxenus writes that the latter used to entice his audience by announcing lectures on the Good or similar philosophical topics, but that eventually these lectures turned out to be on geometry, number theory or astronomy, with the conclusion that "the Good is One." Let me also quote the following passage from Plato's *Philebus* (51b9–c7): "For when I say beauty of form, I am trying to express, not what most people would understand by the words, such as the beauty of animals or of paintings, but I mean, says the argument, the straight line and the circle and the plane and solid figures formed from these by turning-lathes and rulers and patterns of angles; perhaps you understand. For I assert that the beauty of these is not relative, like that of other things, but they are always absolutely beautiful by nature."

Understanding Plato's philosophy has always been, since Plato's times, the most challenging problem in Philosophy. Obviously, the problem has to be addressed by mathematicians and not only by philologists or philosophers as it is usually done. Negrepontis, who is an author of the chapters on Plato's philosophy, is among the very few mathematicians of the modern period who studied Plato thoroughly. He has a fresh point of view on Plato's writings, which I will present briefly in these chapters.

The first of these chapters by Negrepontis is titled ▶ "The Anthyphairetic Interpretation of Knowledge as Recollection in Plato's *Meno* 80d-86e and 97a-98b." The title refers to the *Meno*, a dialogue of Plato whose subject is *knowledge*. Socrates, as in many of Plato's dialogues, is one of the participants to the dialogue. The dialogue starts with a question about the nature of virtue, more precisely, whether it can be taught or whether it is acquired by nature, and if it is not innate, how can one acquire it. The dialogue turns then to the more general question of knowledge, whether it is innate or acquired. Socrates' aim is to prove that knowledge is recollection. Naturally, it appears that "knowledge" for Socrates (and for Plato) is knowledge about mathematics and about abstract and intelligible entities. For this purpose, Socrates calls one of Meno's slave boys, and by way of a succession of questions, he shows that this boy gradually remembers mathematical notions that he has never been taught since birth. The notions concern the irrationality of the diagonal to the side of the square.

Negrepontis, in this chapter, analyzes the two passages of the *Meno* mentioned in the title of the chapter, of which he gives an anthyphairetic interpretation, in line with

other anthyphairetic interpretations he has developed for several other dialogues of Plato. Thus, he shows that Plato's philosophical notion of knowledge in the *Meno*, which amounts to that of the knowledge of a concrete geometrical question, namely, the diameter a of a square given that we know its side b, is in fact the knowledge of the anthyphairesis of a line a satisfying $a^2 = 2b^2$ for a given line b. In philosophical terms, this is the knowledge of True Opinion plus Logos/Logismos. This anthyphairetic interpretation of Plato's philosophy is a recurrent theme in Negrepontis' commentaries on Plato.

The second chapter by Negrepontis, titled ▶ "The Indivisible Line Coincides with the Platonic Intelligible Being," is concerned with the concept of indivisible line, famously referred to by Aristotle who attributes it to Plato and Xenocrates. This interpretation is based on the identification of the indivisible line with Plato's intelligible Being, and a geometric/anthyphairetic interpretation of the nature of the intelligible Being, namely, an intelligible Being is the philosophic analogue of a dyad of opposite kinds in periodic anthyphairesis. The arguments use passages from the *Parmenides*, *Phaedrus*, and *Republic*. In his identification between the indivisible line and the intelligible Being, Negrepontis takes into account ancient sources, first of Plato himself, but also Zeno (especially the second version of the Dichotomy Paradox), Aristotle (the famous and mysterious *Metaphysics* 992a19–22 passage, the *Physics* in his use of the potential infinite as the main argument against Plato and Zeno, and the pseudo-Aristotelean work *On Indivisible Lines*), Proclus, and Simplicius.

The next chapter in this section, by Stelios Negrepontis and Demetra Kalisperi, is titled ▶ "The Mystery of Plato's Receptacle in the *Timaeus* Resolved." In the *Timaeus*, Plato declares, surprisingly, that it is necessary to introduce, beside the intelligibles and the sensibles, a Third Kind, the Receptacle. The nature of the Receptacle and the reason why Plato introduces it has always been a mystery for all Plato's scholars. Negrepontis and Kalisperi give an original response to these two questions, based on well-hidden deep mathematics of incommensurability and of infinite anthyphairesis that underlie Plato's account. The authors argue that these mathematical notions are fundamental not only for Plato's philosophical system of the unchanging intelligible Beings but also for his description of the permanently changing sensible, physical world. The starting point of the article is the interpretation of the intelligible Being as the philosophical analogue of a dyad in periodic anthyphairesis. In his earlier work (e.g., in the *Republic* 475e-480a), Plato identifies the knowledge of a sensible entity with a True Opinion of the intelligible entity N in which this sensible entity participates, namely with a finite initial segment of the infinite periodic anthyphairesis of N. But in the *Timaeus*, Plato's concern is to avoid a Third Man Argument leading to infinite Worlds, and for this Plato needs to transform every finite initial segment of the infinite anthyphairesis of the intelligible into its equivalent, a double tight inequality involving only the two elements of the initial intelligible dyad. Plato realizes that while such a transformation, involving mathematical manipulations, is possible for a geometric anthyphairesis, it makes no sense for an intelligible anthyphairesis. To overcome this difficulty, Plato is obliged to replace the intelligible dyad that generates all the sensibles by the geometrical

(surfaces of the) four regular solids, forming the canonical dyad cube/earth vs. icosahedron/water, augmented by pyramid/fire and octahedron/air. The resulting anthyphairetic inequalities are interpreted by Plato as turning the (geometrized) earth into the Receptacle of the (geometrized) water, air, and fire.

The next chapter, titled "Mathematics in the Being Mode of Existence Mathematics in Abel, Galois, Noether, and Grothendieck," by Victor Pambuccian, is concerned with the work of L. E. J. Brouwer, the founder of the modern intuitionistic school of mathematics. Brouwer was a brilliant mathematician, in particular a great topologist, who tried throughout his academic life to build firm foundations for intuitionistic mathematics. Pambuccian begins his essay by declaring that Brouwer's intuitionism may be unique in the history and philosophy of mathematics for the quality of the hostility it has always encountered from mathematicians and philosophers alike. He recalls that to this day Brouwer's work on intuitionism has not been fully recognized, and that very few mathematicians and philosophers are interested in his intuitionistic mathematics and philosophy of intuitionism. He wonders why this is so. He reviews the few attempts to link Brouwer's work to the works of Aristotle, Descartes and Kant, and to draw parallels with works of Bergson, Husserl, and other Western philosophers. He also reviews Brouwer's conflicts with Hilbert and others, without finding an answer to the above question. Pambuccian's contribution consists in showing the relationship between Brouwer's philosophy and Eastern philosophy, that of Buddha and Krishnamurti and of the Western philosophers close to these Eastern philosophies: Meister Eckhart, Albert Schweitzer, David Bohm, Spinoza, and others. This chapter sheds new light on Brouwer's philosophy, providing a comprehensive overview of the Dutch philosopher and mathematician's life and work, of his position towards the philosophical trends of his time and of his theory of language.

In the next two chapters, by Arkady Plotnitsky, questions such as *What is mathematical practice as Philosophy?* and *What is the working philosophy of mathematics?* are addressed.

The first of these two chapters is titled ▶ "Mathematical Practice as Philosophy, with Galois, Riemann, and Grothendieck." In this chapter, Plotnitsky examines the notion of "working philosophy of mathematics" or, as he likes to say, of "mathematical practice as philosophy." Based on the examples of three paired prominent mathematicians: Abel–Galois, Lobachevsky–Riemann, and Weil–Grothendieck, he starts by explaining how mathematicians' working philosophy of mathematics is closely connected with their actual mathematical thinking and practice. Granting the differences between the thinking of the above mathematicians, his aim is to explore the differences between their mathematical practices as philosophy. Plotnitsky considers that creative mathematical thinking is usually defined by the invention of new concepts and he describes a mathematical theory as being essentially an organized assemblage of concepts. Central to this article are Galois' concept of group, Riemann's concept of manifold and Grothendieck's concept of topos. Plotnitsky's analysis involves a comparison between general creative mathematical practice and that of the two French philosophers Gilles Deleuze and Félix Guattari, who considered that philosophical practice, or even true philosophy itself, is defined

as the practice of the invention of new concepts, with philosophical concepts defined in parallel to mathematical concepts.

In the next chapter, titled "'That Which a Minority Construct': Abelian Mathematics in Abel, Galois, Noether, and Grothendieck – From Galois to Grothendieck," Plotnitsky analyzes the nature of radical transformation in mathematics, enabled by what he calls a "minority mathematics." His discussion mostly concerns what he calls "modern mathematics," that is, the mathematics which emerged as abstract mathematics, roughly around the year 1800, "abstracted," he says, "from mathematics' relations to the natural world and physics, relations that previously dominated mathematics." Referring again to Deleuze and Guattari, the author considers that a minority mathematics is not defined as something that exists entirely outside a "major mathematics" (to be distinguished here from a majority mathematics), but a mathematics that constructs itself inside and even at the very core of this major mathematics. A hint is made to T. Kuhn's revolutionary vs. normal mathematical practice. The cases of N. H. Abel, É. Galois, E. Noether, and A. Grothendieck, as the main cases of revolutionary practice, are central to the discussion.

The next two chapters in this section, one of them written by the author of this introduction and the other one by Alexey Sossinsky, analyze the life and working condition of two mathematicians, one of them a philosopher as well, in the Soviet Union.

The first of these chapters is titled ▶ "Pavel Florensky and His World." It is concerned with the life and works of Pavel Florensky, an important and singular figure of the so-called *Silver Age of Russian mathematics*, a period which is also part of the *Silver Age of Russian literature, poetry, art and philosophy*. Florensky is certainly among the great philosophers-theologians of the twentieth century, with a very atypical trajectory of life. His work in philosophy, the breadth of which is now being discovered (his works are being edited and published at an exponential rate in several languages), is imbued with mathematical ideas, and I think that it is good that this work has started to be known to and analyzed by mathematicians. Florensky developed his *œuvre* in Russia and the early years of the Soviet Union, during the first third of the twentieth century. Talking about Florensky's life and works is also an opportunity to reflect upon the Russian mathematical school of that period, its philosophical foundations, and the conflicts it experienced. It is also an occasion for discussing poetry and literature of the Russian Silver Age.

In the next chapter, titled ▶ "The Practice of Mathematics in a Totalitarian Society," Alexei Sossinsky, based on his own experience, describes the working atmosphere of a mathematician in the Soviet Union at a later period, from 1957 to 1987. This is a period which belongs to the so-called *Golden Age of Russian mathematics*. This chapter provides us with a first-hand picture of this politically turbulent period, which was also a time when mathematics in Russia experienced a development unrivalled in its scope and importance, probably anywhere else in the world.

The next chapter, by Ken'ichi Ohshika, is titled ▶ "Philosophy Behind Mathematics." The author considers the very fruitful interaction between mathematics and

philosophy. One of the themes he develops is that two important philosophical points of view, namely, conventionalism and logical positivism, which are held by mathematicians, but not only by them, were born in works of mathematicians. This is also the occasion to consider the philosophical and mathematical works of some mathematicians-philosophers including Henri Poincaré, who was one of the main figures of conventionalism, and Hans Hahn and Karl Menger, referring to the so-called logical positivism way of thinking. Ohshika explains how the works of Hahn and Menger helped freeing mathematics and philosophy from old Kantian apriorism, both in geometry and logic. Finally, the author addresses the state of a problem which remains unsolved by both conventionalism and logical positivism, namely, the relation between mathematics and natural science.

In the final chapter of this section, titled ▶ "Some Disillusioned Thoughts About School and Teaching," Valentin Ponaru gives an overview of his interests and his experience, since his youth, first in physics, then in philosophy and mathematics. He describes the path that led him to some important philosophical problems, starting from the questions he formulated as a child about the possibility or impossibility of motion, then his discovery of the Greek philosophers like Zeno of Elea, and his reading of Kant. This leads him to some critical thoughts concerning high-school teaching, particularly in France, which he experienced through his children's education.

The Anthyphairetic Interpretation of Knowledge as Recollection in Plato's *Meno* 80d-86e and 97a-98b

Abstract

This chapter aims to obtain a novel anthyphairetic interpretation of Knowledge as Recollection in Plato's *Meno* 80d5-86c3 and 97a9-98b6, in a self-contained manner, in line with the anthyphairetic interpretation I have developed for the whole of Plato's work.

Plato sets out to explain his philosophical notion of Knowledge in the *Meno*, by explaining what he means by Knowledge in the concrete geometrical case of line a such that $a^2 = 2b^2$ for a given line b, in fact of the diameter a of a square with side b. For that purpose, Plato introduces the concepts of True Opinion and Logos/Logismos and formulates his answer as follows:

the *Knowledge* of the diameter a to the side b of a square, $a^2 = 2b^2$ is True Opinion plus Logos/Logismos.

Our interpretation of *True Opinion* is that it consists of the first two anthyphairetic relations of a to b

$a = b + c_1$, $b = 2c_1 + c_2$, and

our interpretation of *Logos* is the Theaetetus' Logos Criterion for periodic anthyphairesis, assuming for the case in question the form of a continuous proportion

$b/c_1 = c_1/c_2$.

Knowledge is then the knowledge of the infinite anthyphairesis of a to b

$$a = b + c_1$$
$$b = 2c_1 + c_2$$
$$c_1 = 2c_2 + c_3$$
$$\ldots$$
$$c_{n-1} = 2c_n + c_{n+1}$$
$$\ldots$$

resulting formally from the two relations above, namely the knowledge of the sequence of the anthyphairetic quotients of a to b [1,2,2,2,...], denoted for short [1, period (2)].

Finally, *Recollection* is a (poetic) reformulation of the repetition c_1/c_2 of the ratio b/c_1, instituting the complete knowledge of the anthyphairesis of a to b.

The *Meno* might appear as an isolated work of geometrical Knowledge, of the dyad <diameter, side of a square>, certainly related to the Pythagorean discovery of the incommensurability of the diameter to the side of a square, but, for Plato, the *Meno* is something more, is, in fact, a paradigmatical case for his philosophical theory of Ideas/True Intelligible Beings, and thus the quest for Knowledge in the *Meno* opens the gate and provides a key for the whole of Plato's philosophy.

The philosophical terms that Plato uses to describe the geometrical situation, namely True Opinion and Logos, fit in his philosophical theory and strongly suggest that for Plato, a true Intelligible Being is a dyad, to wit either the <One, Being> in the second hypothesis of the *Parmenides* or the <Being, not-Being> in the *Sophist*, in the philosophical analogue of anthyphairesis, satisfying the philosophical analogue of Theaetetus' Logos Criterion for anthyphairetic periodicity, as it becomes amply clear in the revealing divisions (of the Angler, Noble Sophistry, and the Sophist) in the *Sophist*, and in the description of the paradigmatical true Being in the second hypothesis in the *Parmenides* in terms of the anthyphairetic division of the dyad <One, Being> plus the circularity of the "hapseis"/logoi.

Knowledge of True Being, namely the dyad <Being, not-Being> is *True Opinion*, namely an initial finite segment of the anthyphairesis of the dyad plus *Logos*, namely the philosophic analogue of Theaetetus' Logos Criterion. Theaetetus' proof of the Pythagorean Proposition: if $a^2 = 2b^2$, then Anth (a, b) = [1, period (2)].

The description of an Intelligible Being and its Knowledge takes various forms in Plato's dialogues but remains largely equivalent to the model introduced in the Meno.

[Part I] The first one and a half steps of the anthyphairesis of a to b ($a = b + c_1$, $b = 2c_1 + c_2$) plus

1 Outline

[Section 2] Computation of the Anthyphairesis of a to b, with $a^2 = 2b^2$ *probably by Theaetetus, the model for Plato's theory of Recollection in the* Meno.

We start with Theaetetus' anthyphairetic definition of the proportion of magnitudes, the Logos Criterion for anthyphairetic periodicity, and the reconstruction of

The reconstruction of the proof, employing tools developed by Theaetetus, consists of:

[Part II] The Theaetetus' Logos Criterion ($b/c_1 = c_1/c_2$) (Proposition 2.5)

The proof in Proposition 2.5 will serve as the model for the whole *Meno* passage on Knowledge as Recollection.

[Sections 3 and 4] *Experimental verification that the knowledge of the duplication of a square is recollection.*

The eristic thesis that knowledge is impossible is juxtaposed to the dialectic thesis that knowledge is possible because knowledge is recollection. *Meno* 80e1-81e3 (Section 3).

An uneducated boy will recollect the knowledge of line a, whose square a^2 with side a is double the square b^2 with the given side b. *Meno* 81e3-82e2 (Section 4).

[Sections 5 and 6 on True Opinion] *Anthyphairetic interpretation of True Opinion in the* Meno*, corresponding to Part I of the proof of Proposition 2.5.*

The initial stage of Recollection of the Knowledge of line a in relation to line b, with $a^2 = 2b^2$, is identified with the geometrical initial segment of the anthyphairesis of line a to line b, with $a^2 = 2b^2$. *Meno* 82e2-83e10 (Section 5).

The philosophic term True Opinion about the line a to b, with $a^2 = 2b^2$ is identified with the geometric term Initial Segment of the Anthyphairesis of a to b, with $a^2 = 2b^2$.

Meno 83e11-d2, 97a9-c5, and *Sumposion* 210a4-e6 (Section 6).

[Section 7] *Heuristics.*

From the anthyphairetic interpretation of True Opinion (Sections 5 and 6) and the statement that *Knowledge is True Opinion plus Something*, we expect (a) that the *Something* needed will be (a philosophic analogue of) the *Logos Criterion* of Proposition 2.3, and (b) that the Knowledge of line a with respect to the line b will be the *full infinite anthyphairesis* of a to b. But this remains to be verified. *Meno* 97c6-d3.

[Section 8] *Name only does not constitute Knowledge.*

The line a, such that its square a^2 is the double of the square b^2 of the given line b, is shown, to be the line with *the name diameter* of the square with side b. The unexpected statement in 85b4 that the name of the line is given by the *sophists*, and not, as would be expected, by the geometers, suggests that Plato has in mind the statement, given in the *Republic* 454a-b, that knowledge by *name (onoma) only is eristic/sophistic* and not dialectical. *Meno* 84d3-85b7.

[Sections 9–12 on Logos] *Anthyphairetic Interpretation of Logos. Knowledge and Recollection in the* Meno is *corresponding to Part II of the proof of Proposition 2.5.*

The first indirect hint of how True Opinion is to be transformed into Knowledge and Recollection is given in terms of the crucial word *pollache. Meno* 85b8-86b5 (Section 9).

For the first time, in *Meno* 86b6-c3, Plato explicitly brings forth the fundamental role of *Logos*. This is certainly no isolated occurrence but by what Plato says, elsewhere, including *Republic* 534b3-6, *Theaetetus* 202c2-5, *Sophist* 260a5-b2, and *Statesman* 286a4-7. Scholars render "logos" by such unhelpful terms as "account," "argument," "discourse," "rational definition," "rational explanation," "reason," and "word" (Section 10).

The revealing interpretation of Logos in the Divisions of the Angler, the Noble Sophistry, and the Sophist in the *Sophist* as the philosophic analogue of Theaetetus' Logos Criterion establishes the nature of Plato's intelligible Being as the philosophic analogue of a dyad in anthyphairetic periodicity (Section 11).

The Logos/Logismos/analogio as *bond* in the *Sophist* 268c5-d5 in connection with our interpretation of the Division of the Sophist in Section 11, in the *Sophist* 251d8-9, 253a4-c1, and in the *Timaeus* leads to the conclusion that the Logismos/Bond in the *Meno* 97d4-98a4 passage is the Logos Criterion $b/c_1 = c_1/c_2$ (Section 12).

[Section 13 on Knowledge, Recollection in the *Meno* as the gate for understanding the whole of Plato's philosophy] Knowledge of the diameter a to the side b of a square is True Opinion (the first two anthyphairetic relations of the diameter to the side) plus Logos (the Logos Criterion $b/c_1 = c_1/c_2$), namely the full knowledge of the infinite anthyphairesis of a to b. This Knowledge is described poetically as Recollection, simply in the sense that the second ratio is a repetition/recollection of the first. Understanding Plato's philosophical terminology (Knowledge, True Opinion, Logos, and Recollection) in a concrete geometrical problem provides valuable insight and confirmation for the whole of Plato's philosophy (Section 13).

2 *Theaetetus' anthyphairetic definition of the proportion of magnitudes, the Logos Criterion for anthyphairetic periodicity, and the reconstruction of Theaetetus' proof of the Pythagorean Proposition: if $a^2 = 2b^2$, then Anth (a, b) = [1, period (2)]*

Our reconstruction of the original Pythagorean proof of the incommensurability of diameter to the side of a square, described in Negrepontis and Farmaki (2019) and Negrepontis et al. (2020), involves heavily the Pythagorean Application of Areas, to computing initial two or three anthyphairetic quotients, and in the form of Preservation of Gnomons, to ensure that the anthyphairesis continues *ad infinitum* as in steps 2 and 3.

We know from the famous Aristotle's *Topics* 158b passage that the first definition of the proportion of magnitudes was in terms of equal anthyphairesis:

2.1. Definition (Theaetetus, cf. Aristotle, *Topics* 158b29-36). If a, b are magnitudes and c, d are magnitudes, then the proportion $a/b = c/d$ holds if the sequence of quotients Anth(a,b) of the anthyphairesis of a to b is equal to the corresponding sequence Anth(c,d) of the anthyphairesis of c to d.

2.2. Proposition (Theaetetus), the **Logos Criterion** for the periodicity of anthyphairesis.

If a, and b are magnitudes, a > b, with anthyphairesis

$$a = k_0 b + c_1,$$

$$b = k_1 c_1 + c_2,$$

$$c_1 = k_2 c_2 + c_3,$$

$$\cdots$$

$$c_{m-1} = k_m c_m + c_{m+1}$$

$$\cdots$$

and there are indices m < n, such that

$$c_m / c_{m+1} = c_n / c_{n+1},$$

then the anthyphairesis of a to b is eventually periodic and in fact
Anth(a, b) = $[k_0,k_1,\ldots,k_{m-1}, \text{period}(k_m,\ldots k_{n-1})]$.

Proof By definition of proportion, $\text{Anth}(c_m, c_{m+1}) = \text{Anth}(c_n,c_{n+1})$. Then
Anth (a, b) =
$[k_0,k_1,\ldots,k_{m-1}, k_m,\ldots k_{n-1}, \text{Anth}(c_n, c_{n+1})]=$
$[k_0,k_1,\ldots,k_{m-1}, k_m,\ldots k_{n-1}, \text{Anth}(c_m, c_{m+1})]=$
$[k_0,k_1,\ldots,k_{m-1}, k_m,\ldots k_{n-1},k_{m-1}, k_m,\ldots k_{n-1}, \text{Anth}(c_n, c_{n+1})]=$
$[k_0,k_1,\ldots,k_{m-1}, k_m,\ldots k_{n-1},k_{m-1}, k_m,\ldots k_{n-1}, \text{Anth}(c_m, c_{m+1})]=$
$[k_0,k_1,\ldots,k_{m-1}, k_m,\ldots k_{n-1},k_{m-1}, k_m,\ldots k_{n-1}, k_{m-1}, k_m,\ldots k_{n-1}, \text{Anth}(c_n, c_{n+1})]=$
$\ldots$
$[k_0,k_1,\ldots,k_{m-1}, \text{period}(k_m,\ldots k_{n-1})]$.

We also need the following elementary:

2.3. Proposition If a,b,c,d are lines, such that ad = bc, then Anth(a,b) = Anth(c,d).

Proof Let Anth(a,b) = $[I_0, I_1,\ldots]$. We proceed by induction. Thus $a = I_0 b + e_1$, with $e_1 < b$. Then $cb = ad = I_0 bd + e_1 d$. By Proposition I.44 of the *Elements*, there is a line segment f_1, such that $e_1 d = bf_1$.

Since $e_1 < b$, it is clear that $f_1 < d$. Thus, $cb = I_0 bd + e_1 d = I_0 bd + bf_1$; then $c = I_0 d + f_1$ with $f_1 < d$. Thus Anth(a, b) = $[I_0,I_1,\ldots]$ = $[I_0, \text{Anth}(b, e_1)]$, while Anth(c, d) = $[I_0, \text{Anth}(d, f_1)]$. Thus, we have that $e_1 d = bf_1$ and we must prove that $\text{Anth}(b, e_1) = \text{Anth}(d, f_1)$.

We continue as in the first step and finish the proof by induction.

We note that the earliest recorded use of (incomplete) mathematical induction to our knowledge occurs for the Pythagorean proof of Pell's property for N = 2 of the side and diameter numbers (examined in Negrepontis et al. (2023), Section 9).

2.4. Proposition (*Pythagorean Theorem*). If a, b, and c are the sides of a right triangle, with hypotenuse c, then $a^2 + b^2 = c^2$.

Proof The Euclidean proof in Proposition I.47 of the *Elements* is, as Proclus states in his *Commentary to Euclid* 426,9-14, due to Euclid. The original Pythagorean proof is most likely based on Proposition II.4 of the *Elements* and is a natural generalization of the special isosceles case, proved in the *Meno*. Negrepontis and Farmaki (2019), Section 5.7 gives a reconstruction along these lines.

2.5. Proposition (*Pythagorean*). If b is a line and a is a line such that $a^2 = 2b^2$, then a is the diameter of the square with side b, and Anth(a,b) = [1, period(2)].

Proof *(Theaetetus)*
[Part I]
By the (isosceles) Pythagorean theorem (Proposition 2.4), line a is constructed as the diameter of the square with given side b. Clearly $a > b$,
Since $a^2 = 2b^2$, it follows that $a < 2b$
(if we had $a \geq 2b$, then $a^2 \geq 4b^2 > 2b^2 = a^2$, contradiction).
Thus, $b < a < 2b$. Hence,
$a = b + c_1$, $c_1 < b$.
It follows that $b > 2c_1$. $3b > 2a$
(if we had $b \leq 2c_1 = 2a-2b$, then $3b \leq 2a$, hence $9b^2 \leq 4a^2 = 8b^2$, contradiction). Hence,
$b = 2c_1 + c_2$.
$b > 2(a-b)$, $3b > 2a$.
[Part II]
Then, $c_1 = a-b$, hence $c_2 = b-2c_1 = b-2(a-b) = 3b-2a$, hence
$b.c_2 = b(3b-2a) = 3b^2-2ab$, and
$c_1^2 = (a-b)(a-b) = a^2 + b^2-2ab = 3b^2-2ab$.

Hence, $b.c_2 = c_1^2$. Since $b > c_1$, and
$b.c_2 = c_1^2$,
clearly $c_2 < c_1$,
thus the second step is indeed anthyphairetic
$b = 2c_1 + c_2$, $c_2 < c_1$.
By $b.c_2 = c_1^2$ and Proposition 1.3, we have
Anth (b, c_1) = Anth (c_1, c_2), namely $b/c_1 = c_1/c_2$, according to the Theaetetean definition.
Then Anth (c_1, c_2) = Anth (b, c_1) = [2, Anth (c_1, c_2)]. Hence,
Anth (a, b) = [1, 2, Anth (c_1, c_2)] = [1,2, Anth (b, c_1) = [1,2, 2, Anth (c_1, c_2)] = ... = [1, period (2)].
Notes. There is no such proof preserved in ancient sources. The geometer who would conceive of such a proof would normally be Theaetetus, since Theaetetus was the first geometer to discover a theory of proportion of magnitudes based on equal anthyphairesis, the pre-Eudoxean theory mentioned by Aristotle in *Topics* 158b.

In the *Topics* passage, there is no explicit attribution, but there is something of a consensus among historians of Mathematics that the theory is due to Theaetetus.

By Proposition 2.5, we obtain *the complete knowledge* of the diameter a with respect to the side a of the square. Since the anthyphairesis of a to b is infinite, by Proposition X.2, a and b are incommensurable.

The computation depends on the representation of the first quotient c_1 as a-b, and of the second quotient c_2 as equal to 3b-2a. These representations use the *side and diameter numbers* q_n, p_n; thus, $c_1 = p_1a\text{-}q_1b = a\text{-}b$, $c_2 = q_2b\text{-}p_2a = 3b\text{-}2a$.

Theaetetus' proof provides *the complete knowledge* of the diagonal with respect to the side of a square with one and a half anthyphairetic division steps plus the Logos Criterion (consisting in the *repetition* of Logos). This *proof* will be our guide for deciphering and interpreting Plato's theory of *Knowledge as Recollection* in the dialogue *Meno*, passages 80e1-86c3 and 97a9-98b6. In turn, this interpretation of *Meno* makes clear that indeed Theaetetus had obtained the present proof.

3 *Eristic logos (knowledge is impossible) vs. dialectic Logos (knowledge is possible because knowledge is recollection).* Meno *80e1-81e2*

The eristic argument holds that knowledge is impossible 80e1-81a4.

> [*Socrates*] Do you see what an *eristic argument (eristikon logon 80e2)* you are introducing—that, forsooth, a man cannot inquire either about what he knows or about what he does not know? For he cannot inquire about what he knows, because he knows it, and in that case is in no need of inquiry; nor again can lie inquire about what he does not know, since he does not know about what he is to inquire.
> *Meno* Now does this argument (*logos*) seem to you to be a good argument (kalos legesthai), Socrates?
> *Socrates* It does not.
> *Meno* Can you explain (*legein*) how not?

[Translation of the *Meno* passages in this present chapter, unless otherwise indicated, are from *Plato in Twelve Volumes*, by W. R.M. Lamb, with modifications, including italicization of some words for emphasis, by the author.]

The dialectic argument holds that Knowledge is Recollection 81a5-d5.

> *Socrates* I can; for I have heard from wise men and women who told of things divine that
> *Meno* What was it they said *(tina logon legonton)*?
> *Socrates* Something true, as I thought, and admirable.
> *Meno* What was it? And who were the speakers *(hoi legontes)?*
> *Socrates* The speakers *(hoi men legontes)* were certain priests and priestesses who have studied so as to be able to provide logos *(logon* didonai*)* of their ministry; and Pindar also *speaks (legei)* and many another poet of heavenly gifts.
>
> As to their words (ha de legousin), they are these: mark now, if you judge these sayings to be true (*alethe legein*). They say that *the soul of man is immortal*, and at one time comes to an end, which is called dying, and at another is born again, but never perishes. Consequently, one ought to live all one's life in the utmost holiness.

"For from whomsoever *Persephone (Phersephona)* shall accept requital for ancient wrong, the souls of these she restores in the ninth year to the upper sun again; from them arise" "glorious kings and men of splendid might and surpassing wisdom, and for all remaining time are they called holy heroes amongst mankind."

Seeing then that the soul is immortal and has been born many times, and has beheld all things both in this world and in the nether realms, she has acquired knowledge (*mematheken 81c7*) of all and everything; so that it is no wonder that she should be able *to recollect* (*anamnesthenai 81c8*), all that she knew (*epistato*) before about virtue (*aretes*) and other things. For as all nature is akin, and the soul has learned (memathekuias 81c9) all things, there is no reason why we should not, by *recollecting* (*anamnesthenta 81d2*) but one single thing—an act which men call *learning (mathesin 81d2)*—discover everything else, if we have courage and faint not in the search; since, it would seem, *research (zetein 81d4) and learning (manthanein 81d4)* are wholly *recollection (anamnesis 81d5).* 81a5-d5

The eristic argument vs. the dialectical argument 81d5-e2.

So we must not hearken to that *eristic* argument (*toi eristikoi logoi* 81d6): it would make us *idle* (argous), and is pleasing only to the indolent ear, whereas the other makes us *energetic (ergatikous) and inquiring (zetetikous 81e1).* Putting my trust in its truth, I am ready to inquire with you into the nature of virtue. 81d5-e2

We can summarize the two opposing arguments:

Eristic logos: Humans cannot search for or attain knowledge, because if you [think you] possess knowledge of something, there is no reason to search for it, and if you do not possess knowledge of something, then you do not know what to search for.

Dialectic logos: Humans have the power to search and attain Knowledge because the human soul is immortal and attains knowledge by recollection (anamnesis) of what she has forgotten.

4 *Experimental verification that knowledge is recollection: an uneducated boy will recall the knowledge of line a, whose square a^2 with side is the double of the square b^2 with given side b*. Meno 81e3-82e2

4.1. *Experimental verification that knowledge is recollection with an uneducated boy.* Meno *81e3-82b8*.

Socrates will show experimentally that "knowledge is recollection" by guiding an uneducated boy to recollect knowledge by himself

Meno Yes, Socrates, but what do you mean by saying that we do not learn (hou manthanom) and that what we call *learning* (mathesin) is *recollection* (anamnesis)?
Can you instruct me that this is so?
Socrates I remarked just now, Meno, that you are a rogue and so here you are asking.
if I can instruct you when I say *there is no teaching but only recollection (anamnesin):* you hope that I may be caught contradicting myself forthwith.
Meno I assure you, Socrates; that was not my intention I only spoke from habit. But if you can somehow prove (endeixasthai) to me that it is as you say, pray do so (enseixai).

Socrates It is no easy matter, but still, I am willing to try my best for your sake. Just call one of your own troop of attendants there, whichever one you please, that he may serve for my demonstration (epideixomai).
Meno Certainly. You, I say, come here.
Socrates He is a Greek, I suppose, and speaks Greek (hellenizei);?
Meno Oh yes, to be sure—born in the house.
Socrates Now observe closely whether he strikes you as *recollecting* (*anamimneskomenos*) or as learning μανθάνων from me.
Meno I will.

4.2. *Definition of square; the area of a square with side b is* b^2. Meno 82b9-d8**.**

Socrates Tell me, boy, do you know that a square figure (*tetragonon chorion*) is like this?
Boy I do.
Socrates Now, a square figure has these lines, four in number, all equal?
Boy Certainly.
Socrates And these, drawn through the middle, are equal too, are they not?
Boy Yes.
Socrates And a figure of this sort may be larger or smaller?
Boy To be sure.
Socrates Now if this side (pleura) were two feet and that also two, how many feet would the whole be? Or let me put it thus: if one way it were two feet, and only one foot the other, of course, the space would be two feet taken once?
Boy Yes.
Socrates But as it is two feet also on that side, it must be twice two feet?
Boy It is.
Socrates Then the space is twice two feet? *Boy* Yes.
Socrates Well, how many are twice two feet? Count (logisamenos) and tell me.
Boy Four, Socrates.

Socrates takes b = 2 feet, but it is clearer if we deal throughout with the general side b. The construction of the square with the given side is in Proposition I.46 of the *Elements,* making use of the Fifth Postulate.

4.3. *Statement of the problem: to obtain the knowledge of line a whose area* a^2 *is double* $2b^2$ *the area* b^2 *of the square with side b*. Meno 82d8-e2

Socrates And might there not be another figure twice (diplasion), the size of this, but of the same sort, with all its sides equal like this one?
Boy Yes.
Socrates Then how many feet will it be?
Boy Eight.
Socrates Come now, try and tell me how long (pelike) will each line (gramme) side of that figure be. This one is two feet long: what will be the side of the other, which is double in size?

At this stage, it is not yet clear what would be considered satisfactory *knowledge of this a.*

5 *The initial stage of Recollection of the Knowledge of line a in relation to line b, with $a^2 = 2b^2$, is identified with the geometrical initial segment of the anthyphairesis of line a to the b, with $a^2 = 2b^2$.* Meno *82e2-83e10*

5.1. *The first anthyphairetic relation of a to b:*
$b < a < 2b$, equivalently $a = b + c_1$, $c_1 < b$,
is the result of successive (ephexes) recollection by the boy under questioning.
Meno *82e2-83e10*

Boy Clearly, Socrates, double.

Let $a^2 = 2b^2$, and it is attempted to obtain the knowledge of line a in terms of the given line b.

The initial reply of the Boy that $a = 2b$ shows that the Boy falsely thinks that he knows the lina a.

Socrates Do you observe, Meno, that I am not teaching the boy anything, but merely asking him each time? And now he supposes that he knows about the line required to make a figure of eight square feet; or do you not think he does?

Meno I do.
Socrates Well, does he know?
Meno Certainly not.
Socrates He just supposes it, from the double size required?
Meno Yes.
Socrates Now watch his *recollecting (anamimneskomenon) in succession (ephexes 82e12), as one must recollect (hos dei anamimneskesthai).*
Tell me, boy, do you say we get the double area from the double line? The space I speak of is not long one way and short the other but must be equal each way like this one while being double its size—eight square feet. Now see if you still think we get this from a double length of the line.
Boy I do.
Socrates Well, this line is doubled, if we add here another of the same length?
Boy Certainly.
Socrates And you say we shall get our eight-foot area from four lines of this length?
Boy Yes.
Socrates Then let us describe the square, drawing four equal lines of that length. This will be what you say is the eight-foot figure, will it not?
Boy Certainly.
Socrates And here, contained in it, have we, not four squares, each of which is equal to this area of four feet?
Boy Yes.
Socrates Then how large is the whole? Four times that area, is it not?
Boy It must be.
Socrates And is four times equal to double?
Boy No, to be sure.
Socrates But how much is it?

Boy Fourfold.
Socrates Thus, from the double-sized line, boy, we get an area, not of double, but of fourfold size.
Boy That is true.
Socrates And if it is four times four it is sixteen, is it not?
Boy Yes.
Socrates What line will give us an area of eight feet? This one gives us a fourfold space, does it not?
Boy It does.
Socrates And an area of four feet is made from this line of half the length?
Boy Yes.
Socrates Very well; and is not a space of eight feet double the size of this one, and half the size of this other?
Boy Yes.
Socrates Will it not be made from a line longer than the one of these, and shorter. than the other?
Boy I think so.
Socrates Excellent: always answer just what you think. Now tell me, did we not draw this line two feet, and that four?
Boy Yes.
Socrates Then the line on the side of the eight-foot figure should be more than this of two feet, and less than the other of four?
Boy It should.

Socrates by questioning him guides him to the "recollection in succession," as he calls the process, in fact to the double inequality

$$b < a < 2b,$$

a condition clearly equivalent to *the first anthyphairetic relation of line a to line* b:

$$a = b + c_1, c_1 < b.$$

5.2. *The (first and the) half of the second step of the anthyphairesis of a to b with* $a^2 = 2b^2$ $b = 2c_1 + c_2$, *equivalently* $2a < 3b$, *are the result of walking (badizon, 84a3-4) on [the road of] recollection under questioning*. Meno *83e1-10.*

Socrates Try (peiro) and tell me how much (peliken) you would say it is.
Boy Three feet (tripous).
Socrates Then if it is to be three feet, we shall add on a half to this one, and so make it three feet? For here we have two, and here one more, and so again on that side there are two, and another one; and that makes the figure of which you speak.
Boy Yes.
Socrates Now if it be three this way and three that way, the whole space will be thrice three feet, will it not?
Boy So it seems.
Socrates And thrice three feet are how many?
Boy Nine.
Socrates And how many feet was that double one to be?
Boy Eight.
Socrates So we fail to get our eight-foot figure from this three-foot line.
Boy Yes, indeed. 83e1-10

It is easily seen that the next step consists in proving the inequality

$2a < 3b$.

[Assume that $2a \geq 3b$. But this cannot happen, since then we would have $8b^2 = 4a^2 \geq 9b^2$, impossible.]

Thus, there is a line c_2, such that $3b = 2a + c_2$, equivalently $b = 2(a\text{-}b) + c_2$, and since $c_1 = a\text{-}b$,

$b = 2c_1 + c_2$,

We don't yet know if $c_2 < c_1$, so this is *half of the second anthyphairetic relation of line a to line b*.

It is clear that these two division steps of the anthyphairesis of a to b form the initial steps of the process of recollection; this is stated explicitly at the beginning (82e12) of the passage 82d5-83d5, where the two anthyphairetic division steps are established, and it is also stated in 84a3-4.

6 *The philosophic term True Opinion about the line a to the given line b, with $a^2 = 2b^2$, is identified with the knowledge of an initial segment of the geometric Anthyphairesis of a to b, with $a^2 = 2b^2$.* (Meno *83e11-84d2, 97a9-c5,* and Sumposion *210a4-e6*)

6.1. *The first two steps of the anthyphairesis of a to b are described as the process of* ***walking towards recollection***. Meno 83e11-84b2.

> *Socrates* But, from what line shall we get it? Try and tell us exactly (akribos 83e11); and if you would rather not reckon it out, just show (deixon) what line it is (84a1).
> *Boy* Well, on my word, Socrates, I for one do not know (ouk oida).
> *Socrates* There now, Meno, do you observe who is already *walking in recollection (badizon hode tou anamimneskesthai*, 84a3-4)? At first, he did not know what is the line that forms the figure of eight feet, and he does not know even now (oude nun oiden):
> but at any rate, he thought he knew (eidenai) then, and confidently answered as though he knew (eidos), and was aware of no difficulty; whereas now he feels the difficulty he is in, and besides not knowing (oiden) does not think he knows (eidenai).
> *Meno* That is true. 83e11-84b2.

6.2. ***True Opinions*** *of the boy about the lines a and b, such that $a^2 = 2b^2$ are* ***formed under questioning***. Meno 84b3-d2.

Compared to the initial false belief of the boy that he possessed knowledge already, the aporia/wonder and realization that he had no knowledge but only some partial initial knowledge, even though this comes as a shock, is a positive and necessary step for the eventual acquisition of knowledge.

> *Socrates* And is he not better off in respect of the matter which he did not know?
> *Meno* I think that too is so.
> *Socrates* Now, by causing him to doubt and giving him *the torpedo's (electric ray's) shock* (*narkan*), have we done him any harm?

Meno I think not.
Socrates And we have certainly given him some assistance, it would seem, towards finding out the truth of the matter: for now, he will push on in the search gladly, as lacking knowledge; whereas then he would have been only too ready to suppose he was right in saying, before any number of people any number of times, that the double space must have a line of double the length for its side.
Meno It seems so.
Socrates Now do you imagine he would have attempted to inquire or learn what he thought he knew when he did not know it until he had been reduced to the perplexity of realizing that he did not know, and had felt a craving to know?
Meno I think not, Socrates.
Socrates Then *the torpedo's shock* (*narkesas*) was of advantage to him?
Meno I think so.
Socrates Now you should note how, as a result of this perplexity, he will go on and discover something by joint inquiry with me, while I merely ask questions and do not teach him; and be on the watch to see if at any point you find me teaching him or expounding to him, instead of questioning him *on his opinions. (doxas)* ething by joint inquiry with me, while I merely ask questions. 84b3-d2

6.3. *True Opinions are described as* ***"ephexes"*** *in* Symposium *210a4-e6.*

Plato, in the *Symposium* 210a-e, describes the ascent to ideal Beauty as at first *"ephexes,"* a process gradual, sequential, and painful, gathering many higher and higher true opinions ("in the first place" true opinion about a beautiful body, 210a6; "but next" true opinion about many beautiful bodies, 210a8; "but after these" true opinions about customs and laws, 210b6; "after" true opinions about all the "mathemata," 210c8); and finally, suddenly and unexpectedly as *"exaiphnes,"* culminating with the revelation of the knowledge of the idea Beauty.

6.4. *Knowledge of the road (hodon, 97a9, b1) to Larisa is likened to Knowledge of the diameter* to the side, and ***walking*** *("badizoi," 97a10) on the road to Larisa is likened to the True Opinions about the diameter to the side.* Meno *97a9-c5*

Socrates I will tell you. If a man knew the road to Larisa (eidos ten hodon ten eis Larisan, 97a9) or any other place you please, and walked (badizoi, 97a10) there and led others, would he not give right and good guidance?
Meno Certainly.
Socrates Well, and a person who had a right opinion (orthos men doxazon) as to which was the road (hodos, 97b1, but had never been there and did not really know (med' epistamenos), might give right guidance, might he not?
Meno Certainly.
Socrates And so long, I presume, as he has right opinion (orthen doxan) about the road, which the other man really knows (epistemen), he will be just as good a guide—if he possesses true opinion (oiomenos men alethe) but not the knowledge of it (phronon de me), —as the man who has the knowledge.
Meno Just as good.
Socrates Hence true opinion (doxa alethes) is as good a guide to the rightness of action as knowledge; and this is a point we omitted just now in our consideration of the nature of virtue when we stated that knowledge is the only guide of right action; whereas we find there is also true opinion (doxa alethes).

Meno So it seems.
Socrates Then right opinion (orthe doxa) is just as useful as Knowledge (epistemes). *97a9-c5.*

6.5. *The identification of the philosophic term* ***True Opinions*** *about the line a to b, with* $a^2 = 2b^2$ *with the geometric term* ***Initial Segment of the Anthyphairesis*** *of a to b, with* $a^2 = 2b^2$.

Under Socrates' questioning, the boy was able to find the first steps of the anthyphairesis of line a to the line b if $a^2 = 2b^2$, in 82b9-84c9; and Plato tells repeatedly in 84c10-d2, 85b8-d2 that the boy is forming true opinions about line a in relation to the line b under Socrates' questioning.

The anthyphairetic relations are described as products of the process towards *recollection*, a process that initially is described as *successive* (*ephexes*, 82e12) recollection and then as *walking* (*badizon*, 84a3-4) towards recollection. In the *Symposium* 210a-e, the True Opinions of the Idea of Beauty are described as ephexes, while in the 97a-d passage, True Opinion is likened to walking the road to Knowledge.

Based on these similarities, we have no hesitation to identify the geometric concept of the initial segment of the anthyphairesis of a to b, with $a^2 = 2b^2$, with the philosophical concept of True Opinion of line a in relation to the line b, for $a^2 = 2b^2$.

We expect that in places where Plato is talking about True Opinion about an intelligible Being, as in the *Symposium*, the *Republic*, the *Theaetetus*, and the second hypothesis in the *Parmenides* that there is some philosophic analogue of anthyphairesis related to the intelligible Being, and that the True Opinion will be a finite initial segment of the anthyphairesis of the intelligible Being.

The identification of the philosophical term True Opinion with a finite initial segment of the anthyphairesis

	Initial anthyphairetic relations of a to b with $a^2 = 2b^2$	True opinions about a to b with $a^2 = 2b^2$
Described as in succession (ephexes)	*Meno 82e12*	*Symposium 210a-e*
Likened to walking (badizein)	*Meno 84a3*	*Meno 97a10*
In the road (hodos)		*Meno 97a9, b1*
Formed as answers of the boy to Socrates' questioning	*Meno 82b9-84c9*	*Meno 84c10-d2, 85b8-d2*

6.6. Bluck (1961) *finds no satisfactory explanation why the process of recollection toward Knowledge should be in order "ephexes."*

Bluck (1961) writes:

> The only rule we are given is that the correct way to recollect is to recollect things '*in order*' (ἐφεξῆς, 82e12), which probably means that one thing must be dealt with at a time, and is perhaps also to be associated with the 'kinship of all nature' and the consequent possibility, through remembering one thing, of being reminded of everything else (81d); *but we are not told what a correct order of remembering might be*. p. 16

ἀναμιμνησκόμενον ἐφεξῆς. We have seen above (81d) that it is possible through remembering one thing to be reminded of another, and it is probably with reference to this fact that Socrates now says that one must recollect things *'in order'*. But we are not told what the relationship is between the things here in question, or *in what order* they should be recollected. *One thinks of the various 'steps' on the 'upward path' of the dialectican's progress in the Republic (511b), where again the precise relationship between the steps is not made clear.*

Probably in our present passage, at any rate, Plato has no very definite relationship or *definite order in mind* but wishes to insist that one thing must be dealt with at a time, since only if a thing is properly understood can we be reminded by it of other things. In this passage, the positive procedure of eliciting from Meno a correct response is bound up with the elenctic or refutative procedelencticure designed to show him that his false answers are false, which continues down to 84a. The refutation of the false answers involves showing Meno what the area is of a square with sides of three feet or o four, and the very recollection of these facts may be regarded as steps towards the recollection of the correct answer to the question about a square of eight square feet. *This is largely a method of trial and error*; but o, discovery can lead to another. Having realized that neither a two- nor three- nor four-feet will give a square of eight square feet, and having before us the diagram of a square of sixteen square feet with transversals . . ., one might well think of halving this latter square (which is what Socrates does), and thereby discover the desired line. Recognition of the nature of the four-foot-sided square and of the three-foot-sided square thus forms part of a thought process that could, and does, lead to the discovery of the correct solution. If this is what Plato had in mind, 'in order' will not refer to any particular series or special procedure, but simply to the desirability of understanding one thing at a time, if ἀνάμνησις is to function through the association of ideas. *No particular order is required*, and no particular relationship between the ἀναμνηστά is implied; but only confusion results from trying to take a second step before the first has been completed (cf. *Phaedo* 101 d-e). p. 297–298 [Italics are added by the author.]

Bluck is attempting to explain in what sense Plato describes as "ephexes," in order, or "badizein," walking in steps, the process of recollection in the *Meno*, and also notes similar descriptions in the *Republic* 511b and the *Phaedo* 101d-e, but also, as we have noted above, in the *Symposium* 210a4-e6, but finds no satisfactory explanation.

Our realization that what Plato is describing in the *Meno*, and in fact in the other cases mentioned by Bluck, are the first steps of the geometric anthyphairesis of line a tu the line b, explains satisfyingly the reason why Plato emphasizes the successive nature of the process.

7 Heuristics: From the statement that Knowledge is True Opinion plus Something (Meno 97c6-d3) and the anthyphairetic interpretation of True Opinion (Sections 4 and 5), we expect that Knowledge will be the full infinite anthyphairesis of a to b and the "something" needed will be the Logos Criterion

7.1 *Knowledge is True Opinion plus Something*

Meno With this difference, Socrates, that he who has *knowledge (epistemen)* will forever (aei) hit on the right way, whereas he who has the right opinion (*orthen doxan*) will sometimes do so, but sometimes not.

Socrates How do you mean? Will not he who always has the right opinion (orthen doxan) be right, so long as he opines rightly (ortha doxazoi)?
Meno It appears to this being the case, that *knowledge (episteme) should ever be more prized (polu timiotera) than right opinion (orthes doxas)*, and why they should be two distinct and separate things. *97c6-d3*

The passage 97c-d in the *Meno* clearly states that the Knowledge of line a that doubles the square of line b is True Opinion plus Something. Since we have identified True Opinion with an initial segment of the anthyphairesis of a to b, it is natural to expect that for Plato, the full Knowledge of a to b will be *the knowledge of the full infinite anthyphairesis of a to b*. From the second part of the proof of Proposition 2.5, we can see that the full infinite anthyphairesis of a to b is obtained with the addition of Theaetetus' Logos Criterion to the first two anthyphairetic relations. Thus, we naturally expect that *Knowledge will be defined as True Opinion plus the Logos Criterion*.

8 *Line a such that its square a^2 is double the square b^2 of the given line b, is shown, to be the line with the name diameter of the square with side b*

However, Knowledge by name (onoma) only is eristic/and not dialectical, as stated in the Republic *454a-b; the sophists promote such an eristic knowledge for the case of the diameter according to* Meno *85b4-5.* Meno *84d3-85b7 and* Republic *454a-b.*

8.1. *The line a such that $a^2 = 2b^2$ is identified in* Meno 84d3-85b7 with **the diameter** of the square with side b.

[*Socrates*]. Tell me, boy: here we have a square of four feet, have we not? Do you understand?
Boy Yes.
Socrates And here we add another square2 equal to it?
Boy Yes.
Socrates And here a third, 3 equal to either of them?
Boy Yes.
Socrates Now shall we fill up this vacant in the corner?
Boy By all means.
Socrates So here we must have four equal areas (choria)?
Boy. Yes.
Socrates Well now, how many times larger is this whole area than this other?
Boy Four times.
Socrates But it was to have been only twice, you remember?
Boy To be sure.
Socrates And does this line,1 drawn from corner to corner, *cut in two equal parts (temnousa dicha)* each of these areas?
Boy Yes.
Socrates And have we here four equal lines containing this area (chorion)?

Boy We have.
Socrates Now consider how large (pelikon) this area (chorion) is.
Boy I do not understand (ou manthano).
Socrates Has not each of the inside lines cut off half of each of these four areas?
Boy Yes.
Socrates And how many areas of that size are there in this part?
Boy Four.
Socrates And how many in this?
Boy Two.
Socrates And four is how many times two?
Boy Twice.
Socrates And how many feet is this area?
Boy Eight feet.
Socrates From what line do we get this figure?
Boy From this.
Socrates From the line drawn corner-wise across the four-foot figure?
Boy Yes.
Socrates The sophists (85b4) call (kalousin) it the diameter (diametron, 85b4):
so if *the diameter (diametros)* is its *name* (*onoma*, *85b5*), then according to you, Meno's boy, the double area (*diplasion chorion*) is the square of *the diameter*.
Boy Yes, certainly it is, Socrates. 84d3-85b7

In passage 84d3-85b7, line a such that $a^2 = 2b^2$ is proved to be the diameter/diagonal of the square with side b. The construction in the present passage of the a as the diameter is the answer to Socrates' second leg of his earlier question in 83e11-84a1, where Socrates had asked first for the *exact (akribos, 83e11)* nature of line a, namely for the complete knowledge of the a, and, failing this, for the lesser knowledge consisting in *showing (deixon apo poias, 84a1)* the line geometrically.

8.2. *Note*. The construction is closely related to a proof of the isosceles Pythagorean theorem and provides a clue for the proof of the general Pythagorean theorem with the use of Proposition II.4 of the *Elements*, a proof that most likely is the original Pythagorean proof of the Pythagorean theorem.

8.3. *However, the rigorous identification of line a with the diameter of the square with side b definitely does NOT provide the Knowledge of line a.*

It is noted and realized by most scholars that, even though the experiment with the boy is ending at this point, full Knowledge of the line a has not been achieved yet.

As Nehamas (1985), p. 22, correctly realizes knowledge and recollection have not been achieved yet:

> Socrates now claims that if 'someone asks him the same questions many times and in many ways' he will finally have as much knowledge about these topics as anyone else (85c9-d11). From this, it is clear that *the slave still does not have episteme* of the subject and Socrates drives the point home by locating the slave in the future in his very next question (*epistesetai*, 85d3-4). He then goes on to say that it is just *this recovery of knowledge state which is still all in the future for the slave, which is recollection*
> (85d6-7)

A clear indication that knowledge has not been achieved yet is noted by Fine (2014), p. 153:

> Socrates speaks of 'the knowledge which he [the slave] now has' (85d9). Socrates has been emphasizing the fact that the slave lacks knowledge. Why, then, does he say that the slave now has knowledge?
>
> One possibility is that he means that, though the slave doesn't have explicit knowledge, he has latent knowledge. However, Socrates doesn't explicitly mention latent or explicit knowledge. He simply says that the slave lacks knowledge and then, at 85d9, that he has it.
>
> We need not infer either that Socrates contradicts himself or that, in saying earlier that the slave lacks knowledge, he was speaking loosely. Nor do we need to invoke both explicit and latent knowledge to avoid contradiction. For the context makes it clear that 'now' (nun) is forward-referring, to the time when the slave will acquire the knowledge he has just been said to lack. The slave doesn't have knowledge in the present; but he will acquire it in the future if all goes well.

This agrees with our heuristic discussion in Sect. 7, according to which the full Knowledge sought in the *Meno* is the full infinite anthyphairesis of the diameter a to the side b of a square.

8.4. *According to* Republic *454a1-9,*
Knowledge by ***Name (kata to onoma) only*** *is eristic, anti-logical, and non-dialectic.*

> "What a grand thing, Glaucon," said I, "is the power of the *anti-logical* (antilogikes) art"
> "Why so?"
> "Because," said I, "many appear to me to fall into it even against their wills, and to suppose that they are acting *not eristically (ouk erizein, 454a5) but dialectically (dialegesthai),* owing to their inability to apply the proper *divisions according to kinds (kat'eide diairoumenoi)* to the subject under consideration, but pursuing the opposition on one another *according to name (kat' auto to onoma, 454a7)*, *eristically (eridi, 454a8), not dialectically (ou dialektoi)*." 454a1-9

We may reach an understanding of Plato's thought if we note that Plato employs the term *"name"* to describe the diameter. In the *Republic* 454a-b and the *Sophist* 218b-219a (cf. Sect. 11.4 below), among other places, Plato regards that the knowledge provided *by name only (onoma monon)* is not true dialectic Knowledge but only an *eristic* one, a term that for Plato has very little difference of meaning from the *sophistic*. So, our present knowledge of line a is at the "name only" level, at the level of knowledge practiced by the sophists.

The comparison of the *Meno* passage 84b-85d, especially Plato's statement that "*the sophists* (85b4) use *the name* (onoma, 85b5) diameter" for the line, which at first may strike us as weird, as we would expect Plato to state that "*the geometers* use the name diameter," is well explained, if we set it next to the *Republic* 454a-b passage, bearing in mind that the practice of the sophists is exactly eristic and non-dialectical. We expect that the term anti-logical for the eristic point of view, implying that the dialectical point of view is logical, will mean that for the dialectical method the Knowledge of the diameter is true and complete when, with the aid of the Logos Criterion, the full infinite anthyphairesis is obtained.

9 *The first rather indirect hint of how True Opinion is to be transformed into Knowledge and Recollection in* Meno *85b8-86b5 is given in terms of the crucial word pollache 85c11*

9.1. *It is repeated that the boy is at the stage of possessing True Opinions but no Knowledge 85b8-c8*

> *Socrates* What do you think, Meno? Was there any *opinion* (doxan) that he did not give as an answer of his own thought?
> *Meno* No, they were all his own.
> *Socrates* But you see, he did not know, as we were saying a while since.
> *Meno* That is true.
> *Socrates* Yet he had in him *these opinions (doxai)*, had he not?
> *Meno* Yes.
> *Socrates* So that he *who does not know* (ouk eidei) about any matters, whatever they be, may have *true opinions* (aletheis doxai) on such matters, about which *he possesses no knowledge (me eidei)*?
> *Meno* Apparently. 85b8-c8.

9.2 *The crucial part of the passage 85b8-86b5 is contained in 85c9-d2, stating that acquisition of Knowledge is achieved by being asked the same questions many times* ***in many places*** *(pollachei, 85c11)*

9.2.a. *Passage 85c9-d2 in Greek*

We first quote the Greek passage 85c9-d2 untranslated.

> ΣΩ. Καὶ νῦν μέν γε αὐτῷ ὥσπερ ὄναρ ἄρτι ἀνακεκίνηνται *αἱ δόξαι αὗται*
> εἰ δὲ αὐτόν τις ἀνερήσεται *πολλάκις τὰ αὐτὰ ταῦτα καὶ* ***πολλαχῇ*** *(85c11),*
> οἶσθ' ὅτι *τελευτῶν* οὐδενὸς ἧττον *ἀκριβῶς ἐπιστήσεται* περὶ τούτων.
> ΜΕΝ. Ἔοικεν. 85c9-d2

9.2.b. *Renderings of 85c9d2 by various scholars translate the crucial word* ***pollachei****, 85c11, in an unhelpful way as* ***"in many ways"*** *or* ***"in a number of different ways."***

Bluck (1961):

> At 85c Socrates said that if someone were to ask the slave *the same questions many times over and in many ways,* then whereas he at present possesses only true opinions, he would come to have *sure knowledge*. The idea seems to be that although the slave has *to some extent* grasped each step of the argument, he would need to go over the whole working many times and in many different ways before he grasped each step *fully* and before he grasped the relationship between the steps and appreciated the argument as a whole, so as to see for himself why the results reached must be correct. This is now to be understood as 'working out the cause', a procedure to be accomplished further 'recollection', and culminating in the attainment of inner conviction. p. 31

Nehamas (1985) writes:

> The slave, Socrates says, will come to have knowledge
>
> 'if one asks him *the very same questions [or: questions about the very same things] many times and in many ways*' (85c10-11)
>
> . . .
>
> Certainly, simply having *many doxai* about geometry cannot be itself sufficient for *episteme*. One must also acquire the ability to organize them systematically, to become able to move from one of them to another properly and on one's own, to know how they are supported by one another. . .. Having the answers to *as many questions as one pleases* does not constitute *episteme* unless one is capable of answering ever new questions as well as of formulating questions of one's own. p. 22–23

Scott (2005) renders pollachei "in many ways":

> At present, these beliefs have just been stirred up in him like in a dream. But if someone questions him *about the same matters on many occasions and in many ways*, you can be sure that he will end up with as exact a knowledge of them as anyone. men. So it seems. 85c9-d1 p. 105

and writes:

> Socrates makes the point by saying, 'if someone questions him about the same matters on many occasions and in many ways . . .'. Some translations render the point as 'if the same questions are put to him on many occasions and in different ways. .' [emphasis added]. This is possible given the Greek but makes little sense. Socrates can hardly be saying that, in order to convert your true opinions into knowledge, you need to be asked exactly the same questions, for you would most likely just continue to repeat the same answers.
>
> Rather, the point is that we should revisit *the same topic or problem but from different angles, and with increasing depth and complexity*. The reference to *different contexts* is very important: the more varied the contexts in which one places the original problem, the more interconnections one makes within one's set of beliefs. This ties in, of course, with the emphasis on synoptic reasoning that I have stressed at various points in this book. It will also be important when we come to examine Socrates' distinction between knowledge and true belief at 98a. p. 106–107

Sedley and Long (2011):

> Socrates: Yes, and now these opinions have only just been stirred up for him as if in a dream. But if someone goes on to question him *about these things on many occasions and in many ways*, you know that eventually, he will have knowledge about them as precise as anyone's. Meno: So it seems. p. 22

Landry (2012):

> At the moment, these beliefs have only just been stirred up in him and it all feels like a dream, but if he were to be *repeatedly asked the same questions in a number of different ways*, he'd certainly end up with knowledge of these matters that is as good and as accurate as anyone's. [85d], p. 163

Fine (2014) also renders "pollachei" as "in many ways":

> And indeed, upon being *questioned further*, the slave arrives at the right answer. Socrates says that the slave still doesn't know the right answer; he just has a true belief about it (85b–d). However, Socrates also says that, if the slave were *questioned further*, he could acquire the knowledge he lacks:
> and now these beliefs have just been stirred up in him as if in a dream. But if someone asks him *these same things many times and in many ways*, you know that eventually, he will know about these things no less accurately than anyone. (85c9–d1) p. 119
> At present, these beliefs have just been stirred up in him, like in a dream.
> But if someone questions him about *these same things often and in many ways*,
> you know that in the end, he will know about these things no less accurately than anyone. (85b8–d1). p.148

The standard rendering of 85c9-d1 appears to be well-described by the phrase:

> εἰ δὲ αὐτόν τις ἀνερήσεται *πολλάκις τὰ αὐτὰ ταῦτα καὶ* ***πολλαχῇ***, οἶσθ' ὅτι *τελευτῶν* οὐδενὸς ἧττον *ἀκριβῶς ἐπιστήσεται* περὶ τούτων.
> if questioned these same things many times ***in many ways***, the boy in the end will have obtained true Knowledge.

In the next section, I will propose that *"pollachei"* should be rendered as *"in many places."*

9.2.c. *Our rendering of the word* ***"pollache"*** *and our tentative anthyphairetic interpretation of 85c9-d2.*

The passage, thus rendered, does not appear convincing. As noted by several scholars, it is hard to see how questioning the boy the same things many times will result in knowledge. If the questions are the same, soon the answers will also be the same, and most likely short of knowledge. We believe that the trouble lies with the rendering of the word "*pollachei*" by "many ways" or by "different ways"; a better rendering of the crucial word "pollachei" is, as indeed suggested by LSJ, "*in many places*" or "on many grounds," and thus our rendering of 85c9-d2 is the following:

> *Socrates* And now those opinions have just been stirred up in him, like a dream;
> but if he were asked *these same questions (ta auta tauta) many times (pollakis) and in many places (pollachei)* you know that he will have in the end as exact an *knowledge* of them as anyone.
> *Meno* So it seems. 85c9-d2

Next, we examine the use of "*pollachei*" by Plato, starting with the following *Parmenides* passage:

> "Then unity is an attribute of *every part of the Being part* and is not wanting to *a smaller or larger or any other part*." "True."
> "Can the one be *in many places* (*pollachou,* 144d1) at once and still be a whole? Consider that question." "I am considering and I see that it is impossible."

> "Then it is divided into parts, if it is not a whole; for it cannot be attached to *all the parts of the Being part* at once unless it is divided." "I agree." 144c6-d4

In this passage, "pollachou" clearly refers to the infinite multitude of the parts of the Being part, generated by the anthyphairetic division of the dyad One, Being, as analyzed in Negrepontis (2024), and each part of the Being part is described as one of the many places. The occurrence of "pollachei" in the *Phaedrus*:

> *Socrates* Conceiving and bringing *together (sunoronta) in one idea scattered (diesparmena) in many places* (pollachei) *Phaedrus* 265d3-4

is exactly in the same sense; the passage describes the fundamental property, the collection of the many into one, of an intelligible Being, namely the equalization of the infinitely many parts dispersed in many places.

Returning to the *Meno* 85c9-d2, we recall that the Socrates-boy questions and answers have started with the anthyphairesis of the diameter a to the side b and have produced the anthyphairetic remainders parts c_1 and c_2, exactly as in the *Parmenides* and the *Phaedrus* passages. So the word "pollachei" refers to these parts, and it is for those that Plato is saying that there should be "the same questions many times about the many parts/places" in which the intelligible Being is being divided by anthyphairesis. Now we are told that if we ask the same questions about the places/parts generated by the anthyphairesisof a to b, then we will achieve complete knowledge, and in fact by Recollection. We can guess, considering the geometrical proof of Proposition 2.5, that *the same question asked many times* that Plato has in mind would be:

What is the ratio of part/place b to the next place c_1?
What is the ratio of part/place c_1 to the next place c_2?

Indeed, complete knowledge is obtained, as seen at the moment we realize that these ratios are the same, the ratio of b to c_1 is equal to the ratio c_1 to c_2, namely when we verify the Logos Criterion.

The same exact conclusion results from the study of the Divisions in the *Sophist*, and their interpretation as the philosophical analogues of geometric periodic anthyphairesis (in Sect. 10 below). In passage 85c9-d2 Plato provides the first hint, for the purpose of predisposing the reader that knowledge will involve a repetition and a recollection, in fact of a logos.

9.3. *The anthyphairetic interpretation is in fact suggestive of Recollection; in fact, asking the same questions many times* ***in many places*** *is described not only as Knowledge but more specifically as Knowledge using Recollection 85d3-86b4*

> *Socrates* Without anyone having taught him, and only through questions put to him, he will acquire *knowledge (epistemen)*, *recovering the knowledge (epistesetai)* out of himself?
> *Meno* Yes.

Socrates And is not this recovery of *knowledge (epistemen)*, in himself and by himself, *recollection (anamimneskestai)*?
Meno Certainly.
Socrates And must he not have either once acquired or always had the *knowledge (epistemen)* he now has?
Meno Yes.
Socrates Now if he always had it, he was always in a state of *knowing (epistemon)*; and if he acquired it all sometimes, he could not have acquired it in this life. Or has someone taught him *geometry* (*geometrein*)? You see, *he can do the same as this with all geometry and every branch of knowledge* (*houtos gar poiesei peri pases geometrias tauta tauta kai ton allon mathematon apanton,* 85e1-3). Now, can anyone have taught him all this? You ought surely to know, especially as he was born and bred in your house.
Meno Well, I know that no one has ever taught him.
Socrates And has he *these opinions (tautas tas doxas)*, or has he not?
Meno He must have them, Socrates, evidently.
Socrates And if he did not acquire them in this present life, is it not obvious at once that he had them and learned them during some other time?
Meno Apparently.
Socrates And this must have been the time when he was not a human being?
Meno Yes.
Socrates So if in both of these periods—when he was and was not a human being—he has had *true opinions (aletheis doxai)* in him which have only to be *awakened (epegertheisai)* by questioning to become *knowledge (epistemai)*, his soul must have had this cognizance throughout all time? For clearly he has always either been or not been a human being.
Meno Evidently.
Socrates And if *the truth of all true Beings* is always in our soul, then *the soul must be immortal*; so that you should take heart and, whatever you do not happen *to know (epistamenos)* at present—that is, what you do not *remember (memnemenos)*—you must endeavor to search out and *recollect (anamimneskestai)*? 85d3-86b4

In case our intuition is correct and Knowledge is precisely the knowledge of the full infinite anthyphairesis of the diameter to the side of a square using the Logos Criterion, as we have indicated in the heuristic Sect. 6, then we must have no difficulty describing this process as Recollection. Indeed, Knowledge is obtained at the precise moment that we realize that a previous logos (of successive parts in the anthyphairesis) is equal to a logos (of two successive parts of the anthyphairesis at some later stage). This repetition can be validly and interestingly be somewhat poetically described as Recollection. As we shall see later, Recollection, according to both Plato and Proclus, is specifically the Recollection of Logoi.

9.4. *Despite Plato's broad hint with "pollachei," the method of turning True Opinions into Knowledge and Recollection still remains a mystery to Meno and to most readers of Plato, whose resolution needs more explicit help 86b5*

Meno What you say is for me a good Opinion (eu moi dokeis), Socrates, but I know not how**.** 86b5

So Meno realizes that he is still in the state of Opinion, and a clearer description of the process of acquiring Knowledge by Recollection is necessary.

10 *For the first time, in the* Meno *86b6-c3, Plato explicitly brings forth "logos" as the fundamental ingredient of Knowledge, in line with a corresponding role for "logos" in the* Republic 534b3-6, Theaetetus 202c2-5, Sophist 260a5-b2, Statesman 286a4-7, *and elsewhere in Plato. Platonic Scholars render "logos" by terms such as "account," "argument," "discourse," "rational definition," "rational explanation," "reason," and "word"(cf. Sections 10.2 and 10.3). These renderings in our opinion are not in the correct direction and obscure the true meaning of "logos." Nehamas (1984) suggested that the meaning of Logos must come from a study of the Divisions in the* Sophist *and the* Statesman. *This is exactly our approach in Sections 11 and 12*

10.1. Meno *86b6-c3 on Logos*

We have noted that knowledge has not been acquired at 85b7. It is further clear that even at 86b5, it has not been explained how true opinions turn into recollection and knowledge:

> [*Socrates*] Most of the points I have made in support of ***Logos*** (*huper tou logou*, 86b7) are not such as I can confidently assert; but that the belief in the duty of inquiring after what we do not know will make us better and braver and less helpless than the notion that there is not even a possibility of discovering what we do not know, nor any duty of inquiring after it—this is a point for which I am determined to do battle, so far as I am able, both using ***Logos*** (*kai logoi*, 86c2) and work.
>
> *Meno* There also I consider that *you provide Logos* (legein) well, Socrates. 86b5-c3

We note that in the W.R.M. Lamb classical translation of the passage, the first occurrence 86b7 of *Logos* is rendered as *"argument,"* while the second 86c2 as *"word."*

10.2. *The renderings of the crucial term "logos" in 86b7 and 86c2 by Platonic scholars "argument" and "word," respectively.*

R. E. Allen (1959):

> There are other things about the *argument* that I would not confidently affirm, but that we shall be better men, more courageous and less idle, if we think we ought to inquire into what we do not know, instead of thinking that because we cannot find what we do not know we ought not to seek it – that I would do battle for, so far as possible, in *word* and deed. (86b6-c2, in Halper 2007, p. 239)

J. Klein (1965):

> For he goes on *asserting*, forcefully and without any ambiguity, that in all that was said there was only one point (81 d 5- e 1; 86 b 2 - 4) for which he would fight strenuously, *in word* and deed (kai logdi kai ergoi), whenever he was able to do so. p.182

D. Scott (2005):

As for the other points, I wouldn't absolutely insist on *the argument.*
But I would fight, both in *word* and deed, for the following point:
that we would be better, more manly, and less lazy if we believed that we ought to inquire into what we do not know, than if we believed that we cannot discover what we do not know and so have no duty to inquire. (86b6–c2) p.121.
Logos is rendered as argument and word.

Waterfield (2005):

Socrates: Yes, I think so too, Meno. I wouldn't support every aspect of *the argument* with particular vigour, but there's one proposition that I'd defend to the death, if I could, by *argument and by action*: that as long as we think we should search for what we don't know we'll be better people– less fainthearted and less lazy– than if we were to think that we had no c chance of discovering what we don't know and that there's no point in even searching for it. p. 124
Logos is rendered as argument.

Ebert (2007):

So I seem to myself, Meno. All the other points I have made in support of *the argument* are not such as I can confidently assert; but that, if we are convinced we should inquire after what we do not know, we should get better and braver and less lazy than if we believe that we are neither able nor obliged to inquire after things we do not know – this is something for which I am determined to fight, so far as I am able, both in *word and deed*. (86b6-c2) p. 197

Sedley and Long (2011):

Socrates: I think so too, Meno. In defense of *the argument* I would not affirm the other points very strongly, but that we would be better, more manly, and less lazy by believing that one should search for what one doesn't know than if we believed that we cannot discover what we 86c do not know and should not even search for it – that is something over which I would fiercely contend, if I were able, in both *word and deed*. p. 23

Fine (2014):

As far as the other points (ta alla) are concerned, I wouldn't altogether take a stand on *the argument*. But that we will be better and more manly and less idle if we think one should inquire into that which one doesn't know than if we think it isn't possible to discover what we don't know and that we don't need to inquire into it: that is something I would certainly fight for to the end, if I could, in both *word and deed*. (85d12–86c2) **p. 150**

Benson (2015):

I would not confidently assert the other things said in defense of this *account,* but that we would be better and braver and less idle if we believe that one ought to inquire concerning those things he fails to know than if one believes it is not possible to discover nor necessary to inquire concerning those things one fails to know (εἰ οἰοίμεθα ἃ μὴ ἐπιστάμεθα μηδὲ δυνατὸν εἶναι εὑρεῖν μηδὲ δεῖν ζητεῖν), I would fight for in both ***word*** *and deed* as far as I am able. (Meno 86B6–C2; emphasis added) p. 62

10.3. *At this point, it is necessary to realize that in several other passages in Plato, where "logos" is described as an absolutely fundamental ingredient of Knowledge, the renderings of the term,* as *"account," "discourse," "rational definition," "rational explanation," reasonby various scholars of Plato, seriously obscure its real meaning.*

Republic *534b3-6:*
And do you not also give the name *dialectician (dialektikon)* to the man who is able to exact *an account (logon)* of the true Being of each thing? And will you not say that the one who is unable to do this, in so far as he is incapable of rendering *Logos (logon)* to himself and others, does not possess intelligence[2] about the matter?

Note. *Logos* is rendered in the classical translation by P. Shorey as *account.*

Theaetetus *202c2-5:*
for he who cannot give and receive *Logos* (logon) of a thing is without knowledge (anepistemona) of it; but when he has acquired Logos (logon) he may possibly have become all that I have said and may now be perfect in *knowledge (epistemen).*

Note. *Logos* is rendered in the classical translation by H.N. Fowler as *rational explanation*.

Sophist *260a5-b2. Logos is necessary for the Knowledge of intelligible Beings*
Stranger Our object was to establish that *the Logos (logon)* is one of the kinds of the Beings (ton onton). For if we were deprived of *this [Logos]*, we would be deprived of philosophy, which would be the greatest calamity; moreover, we must at the present come to an agreement (diomologesasthai) about the nature (ti pot' estin) of *Logos (λόγου)*, and if we were robbed of *it [Logos]*, there would be no true Being (med' einai) and we could no longer be able to provide *Logos (legein), and* we should be robbed of *it [Logos]*, if we agreed that there is *no mixture (meixin)* of anything with anything.

Note. The classical translation by H.N. Fowler renders all six references to "Logos" as "discourse."

Statesman *286a4-7. Logos necessary for the Knowledge of Intelligible Beings*
We must therefore study so as to have the power (dunaton einai) *to give and receive (dounai kai dexasthai) the Logos* (logon) of each of them; for the immaterial *[intelligible] Beings*, which are the noblest and greatest, can be made known (saphos deiknutai) *by Logos (logoi) only*, and it is for their *[the intelligibles']* sake (heneka) that all *Logoi* are provided *(legomena).*

Note. The classical translation by H.N. Fowler renders "logon" as "rational definition," logoi as "reason," and "legomena" as "all we are saying."

10.4. *Interestingly*, Nehamas (1984) *suggested that the meaning of Logos in Plato is to be found in the divisions of the* Sophist *and* the Statesman. *This is exactly our approach in Sections 11 and 12.*

Nehamas (1984) expresses the opinion that the meaning that Plato has in mind with Logos must come from a study of the Divisions in the *Sophist* and the *Statesman.*

The answer [to the meaning of Logos in Plato] can only be given using the long and complicated divisions through which the *Sophist* and the *Politicus* attempt to define their subject matter. Both dialogues try to define a species of art (techne) or science (episteme), that of the sophist and that of the statesman (cf. Pol, 258b2-7). In both dialogues, the art in question is defined by being located within a determinate network of other arts and sciences. And the process by means of which the definition is reached provides, at the same time, both an explanation of the aporetic ending of the *Theaetetus* and an Illustration of the obscure

opening of the *Philebus*. Plato, therefore, does try to answer the question of *Theaetetus*. But his answer is not cryptically contained within the dialogue itself, either negatively (äs Cornford argued) or positively (äs Fine suggested). His answer is given in the two dialogues that follow the *Theaetetus*. p. 36

11 *The revealing anthyphairetic interpretation of Logos in the Divisions of the Angler, the Noble Sophistry, and the Sophist in the* Sophist *as the philosophic analogue of Theaetetus' Logos Criterion establishing anthyphairetic periodicity*

11.1. *Plato considers that the clearest demonstration of the nature of Logos is provided in the last division of the Sophist in the* Sophist *264b-268d*

Towards the end of the *Sophist*, after having given a considerable number of hints and suggestions, Plato is not yet sure that he has made his point clear, and Theaetetus is still not convinced of the crucial importance of "logos" for achieving knowledge of intelligible Beings:

Theaetetus That is true enough, but I do not understand why we must come to an agreement about [the crucial importance of] *logos* [H. N. Fowler renders *logon* by *discourse*] just now. *Stranger* Perhaps the easiest way for you to understand is by what follows. 260b3-5

The final step is the demonstration of the power of *logo*s with the definition of the Sophist using a dyad Being not-Being, as noted explicitly in 258eb-7, possessing *logos*, in the *Sophist* 234e-236d & 264b-268d at the very end of the dialogue.

11.2. *The anthyphairetic nature of Logos is revealed in the* Sophist and Statesman *Divisions*

Indeed, the best way to come to an essential understanding of what Plato means with Logos is to study the Divisions in the *Sophist* and in the *Statesman*. The meaning is revealed to be anthyphairetic in S. Negrepontis (1999, 2000a, 2000b, 2012, 2018), p.350–367; (2019), p. 28; and Negrepontis et al. (2023). For completeness, we will include an analysis of the *Sophist* divisions, in the present Section: on the Angler in the *Sophist* 218b-221c (Sect. 11.5), on the Noble Sophistry (Sect. 11.6), and on the Sophist (Sect. 11.7). The anthyphairetic interpretation of the Logos in the *Sophist* Divisions will play a crucial role in our interpretation of the *Meno* passages in the next Sect. 12.

11.3. *According to* Sophist 218b5-c5, 218e2-219a3 **intelligible** Knowledge (episteme) is not only **Name** but also **Logos**

Stranger Very well (Εὖ λέγεις); you will follow your own devices about that as *Logos (tou logou) proceeds*; but now you and I must investigate in common, beginning first, as it seems to me, with *the sophist,* and must search out and make plain *by means of logos (logoi)* what he is *(ti pot' esti)).* For as yet you and I have in common about him [the sophist] *only the name (tounoma monon)*, but as to the Being itself to which we give *the name*, we may perhaps each have a conception of it in our own minds; however, we ought always in every

instance to come to an agreement about it *by means of logoi* rather than about *the name only (tounoma monon) without (choris) Logos (λόγου)*. 218b5-c5

Stranger Well, then, what example can we set before us which is well-known and small, but no less capable of *Logos (logon) than any* of the greater things? Say *an angler (aspalieutes)*; is he not known to all and unworthy of any great interest?

Theaetetus Yes.

Stranger But I hope he offers us *a method (methodon)* and is capable of a *Logos (logon)* not unsuitable to our purpose.

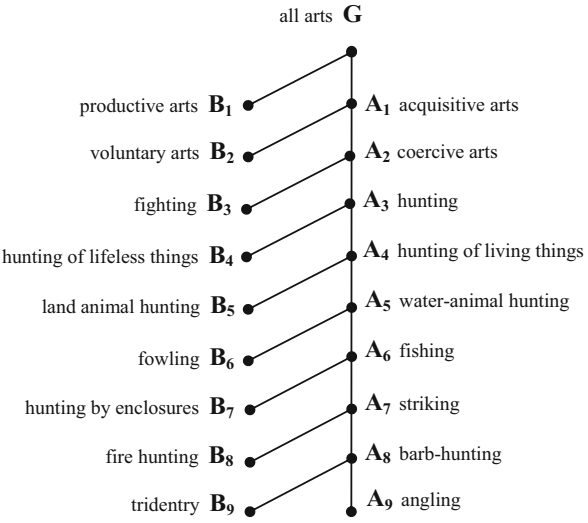
Theaetetus That would be good. 218e2-219a3

Note. "Logos" is rendered as "rational explanation," "argument," and "definition" by the same translators.

11.4. *Name and Logos of the intelligible Being Angler in the* Sophist 218b-221c.

11.4.a. *The Division of the Angler*

The method of "Name and Logos" (cf. *Theaetetus* 201e2-202b5, *Sophist* 218c1-5, 221a7-b2, 268c5-d5) is exemplified at the start of the *Sophist* 218b-221c by the definition of the Being Angler. The Angler is certainly a lowly paradigm of an intelligible Being, but even for lowly entities, there is an intelligible Being, cf. *Parmenides* 130b7-e3. In the scheme below, we reproduce the binary division process which leads to the Angler.



The Division of the Angler (*Sophist* 218b-221c)

11.4.b. *Logos Criterion of the Angler*

The description of the Logos Criterion of the Angler is contained in the *Sophist* 220e2-221c3 passage (which we have divided into two parts [A] and [B] for the sake of convenience):

[A] '*Stranger* Then of striking which belongs to barb-hunting [A8],
that part which proceeds *downward from above* ('anothen eis to kato'),

is called, because tridents are chiefly used in it, tridentry [B9],
I suppose. . ..
Stranger The kind that is characterized by the opposite sort of blow,
which is practiced with a hook and strikes, ...
and proceeds *from below upwards* ('katothen eis tounantion ano'),
being pulled up by twigs and rods.
By what name, Theaetetus, shall we say this ought to be called?
Theaetetus I think our search is now ended and we have found the very thing we set before us a while ago as necessary to find.
Stranger: Now, then, you and I are only agreed about the name of angling, [A9]'
220e2-221b1
[B] 'but *we have acquired also a satisfactory 'Logos'* of the thing itself.
For (gar)
of art as a whole, half was acquisitive,
and of the acquisitive, half was coercive,
and of the coercive, half was hunting,
and of hunting, half was animal hunting,
and of animal hunting, half was water hunting,
and of water hunting [A5]
the whole part from below (to katothen tmema holon) was fishing, [A6]
and of fishing, half was striking,
and of striking half was barb-hunting, [A8]
and of this [A8]
the part in which the blow is pulled
from below upwards *(to peri ten katothen ano)* was angling. [A9] (221b1-c3).
[Translation by H. N. Fowler (1921), with modifications by the author.]

In [A], the opposing relation of Tridentry to Angling is carefully explained: all Fishing with a hook is divided into

Tridentry (=Fishing with a trident), which is described as
Fishing with a hook with an art that proceeds **from above downwards**, and
Angling (=Fishing with a rod), which is described as
Fishing with a hook with an art that proceeds **from below upwards**
We have pushed Division all the way to the Angling; thus, we have certainly found 'the name' of Angling.

But now, in [B], it is claimed that "the Logos" of the Angling has been found, too.

The justification – the proof – that we have indeed found the Logos, too, is contained in the remainder [B], since this remaining part [B] starts with a "for" ("gar"), and this justification can be seen to consist of:

(i) An accurate recounting of all the division steps, abbreviated in the sense that of the two species into which each genus is divided, only the one that contains the Angler is mentioned, while the species opposite to it is omitted.
(ii) A reminder that the last species, the angling, is characterized as the part of its genus that proceeds "from below upwards."
(iii) The ONLY new information (since (i) and (ii) are repetitions of things already contained in the Division and in [A]), which concerns the species of fishing, three steps before angling, and which informs us for the first time that this species is "the whole part from below" of its genus.

Since this is an abbreviated account, there is no explicit information on the species opposite to "fishing" – namely "fowling," but since "fishing" was described not simply as "the part from below" of its genus, but emphatically as "the whole part from below," it follows that the opposite species – "fowling" – must be characterized as "the (whole) part from above" of the same genus. In fact, there can be no other justification for the presence of the term "whole" in the description of "fishing" with a view to arguing that we have obtained "Logos," except to indicate and imply this description for its opposite species, "fowling."

We recall that the part [B] from the word "for" ("gar") is explicitly a justification of the claim that we have succeeded in finding the "Logos" of the Angling. We may then ask: what is the "Logos" of the Angler that reasonably results from such a justification? There can really be only one answer: the "Logos" we are looking for is the equality of the "philosophic ratio" of Tridentry to Angling, namely the equality of the ratio "of from above downwards to from below upwards," to the ratio "of Fowling to Fishing."

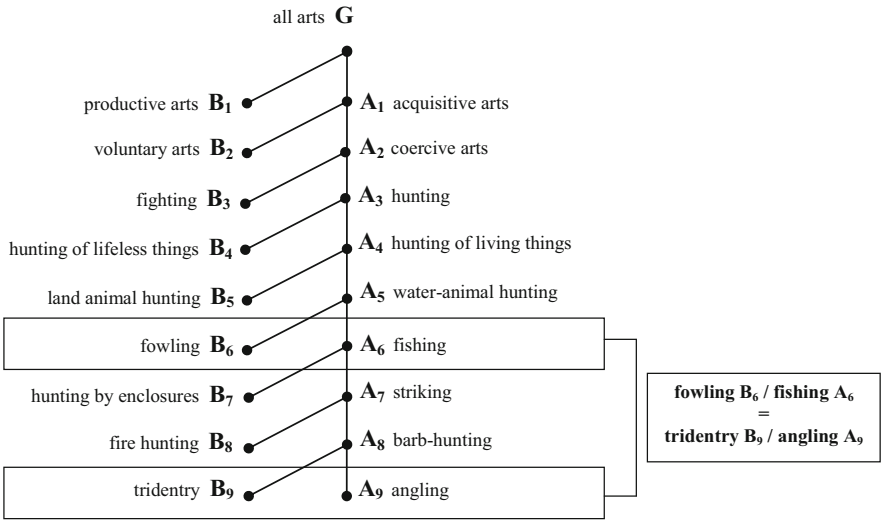
Thus,

fowling B6/fishing A6 = tridentry B9/angling A9 =
from above downwards/from below upwards.

Since the species Tridentry and Angling form a pair of opposite species, and the species Fowling and Fishing form another pair of opposite species in the Division Scheme for the Angler, the resulting "Logos" bears a most uncanny similarity to the Logos Criterion for the periodicity of the anthyphairesis of geometric magnitudes and of geometric powers in particular.

11.4.c. *The Name and Logos of the Angler.*

The Name and Logos of the Angler thus takes the following form:



Thus, the Name and Logos of the Angler consists of the anthyphairetic division together with the Logos, analogous to the Logos Criterion for periodicity for geometric anthyphairesis.

11.5.*The Interpretation of Logos in the Definition of the* ***Noble Sophistry*** *by* ***Name and Logos*** *in the* Sophist 226c-231b as the philosophic analogue of the Logos Criterion establishing periodic anthyphairesis.

We outline the Name and Logos of the intelligible Being *Noble Sophistry* in the *Sophist*.

G The art of discrimination/separation (diakritike), 226c	
a1 Separation of like from like, 226d	b1 Separation of worse from better, 226d=purification (kathartikon), 226d

b1 Purification (kathartikon)	
a2 Purification of the body, 227c	b2 Purification of the soul, 227c

b2 Purification of the soul	
a3 Purification from wickedness, 228d=justice (kolastike) 229a Rougher purification of the soul (trachuteron)	b3 Purification from ignorance, 228d=instruction (didaskalike) 229a Smoother purification of the soul (leioteron)

b3 Instruction (didaskalike)	
a4 Instruction in handicraft, 229d	b4 Instruction in logoi, 229d =education (paideia) 229d

[Question whether education is “already indivisible” or still admits of division 229d]

b4 Education (paideia)	
a5 Admonition (nouthetike) 230a Rougher education (trachuteron),229e	b5 Noble sophistry, dialectic 231b Smoother education (leioteron) 229e

Logos Criterion for anthyphairetic periodicity:

a3/b3 = a5/b5 = rougher/smoother

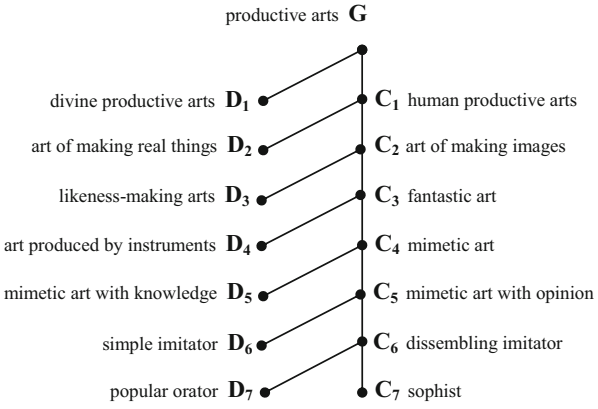
The definition of the Noble Sophistry by Name and Logos exhibits the same structure of anthyphairetic periodicity as the Angler.

11.6. *The Name and Logos of the Intelligible Being* ***Sophist*** *in the* Sophist *234e-236d and 264b-268d*

It appears that the Name and Logos of an intelligible Being is very much like the anthyphairetic Division and the Logos Criterion of a geometric "power." When Socrates expressed, in the *Theaetetus* 45c7-148e5, his exhortation to imitate the geometric situation, it seems that he meant a much closer imitation than anybody has thus far suspected! But before proceeding to wide-ranging conclusions, it would be prudent to examine whether the Name and Logos of the Sophist, in the *Sophist* 264b-268d, has the same kind of structure and, in particular, whether there is a similar type of "Logos." So we shall take a look at the Name and Logos of the Sophist.

11.6.a. *The Division of the Sophist*

The Division for the Sophist follows the same pattern as the Division of the Angler, starting with a Genus, in this case "all the productive arts," proceeding by binary division of each Genus to two species, where the next Genus is that species of the previous step in the Division that contains the entity to be defined, in this case, the Sophist, and ending with the division step that produces the Sophist as a species. The whole division scheme is as follows:



Division of the Sophist (*Sophist* 264b-268d)

11.6.b. *The fundamental analogy in the Divided Line of the Republic 509d-510b and the Logos Criterion of the* Sophist

We will make essential use of the fundamental analogy in the Divided Line of the *Republic* 509d-510b:

the opinable/the knowable = the likeness/that of which it is a likeness.

A strong indication that Plato's intention was to use the *Republic*'s ratio of the Divided line is the extra care he takes to justify the equality of the *Republic* ratio, namely the ratio of all likenesses-images to all real things, all meaning both divine and human, to the ratio in the Sophist, namely the ratio of human likenesses-images (C2) to human real things (D2). He does this meticulously in *Sophist* 265e8-266d7,

in which there is a division not only of C1 into D2 and C2 but also of D1 into the arts producing real things (say D2') and into the arts producing images (C2'), a division of a "rejected" species, something unexpected and unique in Plato's divisions. The proof of equality, involving "breadth" and "width," employs an analogue of Proposition VI.1 of Euclid's *Elements*.

The Logos Criterion for the Sophist is now immediately recognized:

Proposition.

The ratio of the second step in the Division of the Sophist, namely the ratio of the art of making *real things* **D2** to the art of making *images* **C2**	is equal to	the ratio of the fifth step in the Division of the Sophist, namely the ratio of the mimetic art *with knowledge* **D5** to the mimetic art *with opinion* **C5**

11.6.c. *The next two Logoi of the Name and Logos of the Sophist are analogous to the geometrical ratios of periodic anthyphairesis.*

The definition of the Sophist presents an additional feature that ties it even closer to the mathematical model: there are two Logoi after the Logos Criterion, and if the mathematical anthyphairetic model is indeed followed, we would expect to have two further equalities of Logoi: namely the logos of the third step should be equal to the ratio of the sixth division step, and the logos of the fourth division step should be equal to the ratio of the seventh and final division step.

(c1) *The equality of the third and sixth ratios of the Division of the Sophist*. In the third division step, the Genus "humanly produced images" is divided into two species,

> *Stranger* I see the likeness-making art (eikastiken) as one part of [the image-making art]. This is met with, as a rule, whenever anyone produces the imitation by following the proportions of the original in length, breadth, and depth, and giving, besides, the appropriate colors to each part. 235d6-e2
> *Stranger* Now then, what shall we call that which appears, because it is seen from an unfavorable position, to be like the beautiful, but which would not even be likely to resemble that which it claims to be like if a person were able to see such large works adequately? Shall we not call it, since it appears, but is not like, an appearance?
> *Theaetetus* Certainly. 236b
> Stranger And to the art which produces appearance, but not likeness (phantasma all' ouk eikona), the most correct name we could give would be "fantastic art," (phantastiken) would it not?
> *Theaetetus* By all means.
> *Stranger* These, then, are the two forms of the image-making art (eidolopoiikes) that I meant, the likeness-making (eikastikes) and the fantastic (phantastikes). 236c3-7
> *Stranger* We must remember that there were to be two parts of the image-making class (eidolourgikes), the likeness-making (eikastikon) and the fantastic (phantastikon). 266d8-9

Thus, the likeness-making art is an image that does not distort the original object but rather expresses a *faithful* likeness of that object, while in the sixth division step, described in 267e7-268a8, the Genus opinionated-imitator is divided into the two

species, "the simple" (haploun) and "the dissembling" (eironikon) opinionated-imitator, the simple imitators being those who

> think they know that about which they have only opinion,

while the "dissembling" are those who

> because of their experience in the rough and tumble of arguments, strongly suspect and fear that they are ignorant of the things which they pretend before the public to know.

Thus, the simple imitators *do not distort* their opinion but rather express a *faithful* likeness of their opinion, while the dissemblers *distort and disguise* their opinion behind a false appearance.

Therefore, we have

Proposition.

The ratio of the third step in the Division of the Sophist, namely the ratio of *the likeness-making arts* D3 to *the fantastic arts* C3	is equal to	the ratio of the sixth step in the Division of the Sophist, namely the ratio of *the simple imitator* D6 to *the dissembling imitator* C6

(c2) *The equality of the fourth and seventh ratios*. In the fourth division step, described in 267a1-b3, the Genus, fantastic arts, is divided into two species, as follows:

> *Stranger* Let us, then, again bisect the fantastic art.
> *Theaetetus* How?
> *Stranger* One kind is that produced by instruments, the other that in which the producer of the appearance offers himself as the instrument.
> *Theaetetus* What do you mean?
> *Stranger* When anyone, by employing his own person as his instrument, makes his own figure or voice seem similar to yours, that kind of fantastic art is called mimetic.
> 267a1-b3

Thus, in mimetic art, the instrument of imitation is the imitator himself, while in the nameless opposite art, the instrument of imitation is other than the imitator.

In the seventh division step, described in 268a9-c4, the dissembler is divided into the demagogue and the sophist, the demagogue being

> one who can dissemble in long speeches in public before a multitude,

while the sophist is someone

> who does it in private in short speeches and forces the person who converses with him to contradict himself.

Thus, he who listens to a dissembler is deceived, if that dissembler is a demagogue, and contradicted not by himself but by another instrument of deceit (namely the demagogue himself), while if the dissembler is a sophist, the listener is forced by the sophist to himself become the instrument of deceit.

Thus, we have:

Proposition.

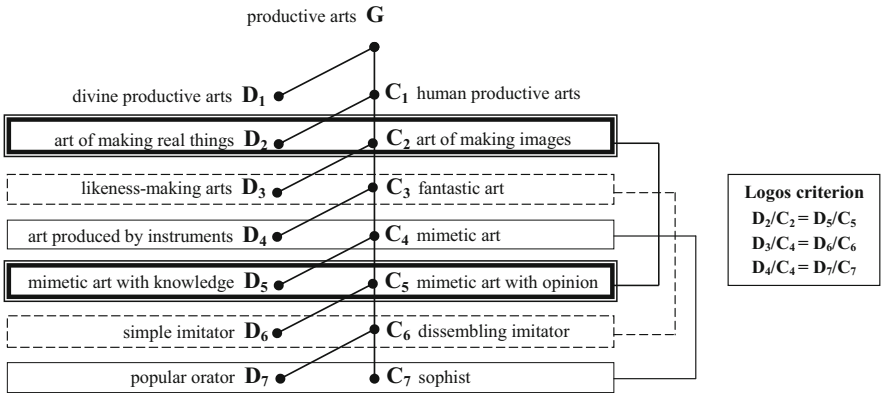
The ratio of the fourth step in the Division of the Sophist, namely the ratio of the imitator who uses *not himself, but other* instruments of imitation D4 to the imitator who is *himself* the instrument of imitation C4	is equal to	the ratio of the seventh step in the Division of the Sophist, namely the ratio of the demagogue, whose listener is contradicted and deceived *not by himself but by other* D7 to the sophist, whose listener is contradicted and deceived *by himself* C7

Propositions (C1) and (C2) provide powerful additional evidence in favor of the anthyphairetic interpretation of Division and Collection.

11.6.d. *The Name and logos of the Sophist*

The complete Name and Logos of the Sophist (*Sophist* 264b-268d) can thus be summarized in the following scheme:

The definition of the Sophist by Name & Logos
as the philosophic analogue of periodic anthyphairesis 264b-268d, 258b5-7



Thus, we have full confirmation for the anthyphairetic meaning of Logos that we proposed in the Name and Logos of the Angler. This time, the Logos is not of the simple-minded, obvious type that appeared in the definition of the Angler (from above downwards/from below upwards), but of a more sophisticated and philosophical kind, playing a central role in the dialectics of the *Republic.*

We note that the correlation of the *Republic* ratio in the divided line with the Name and Logos of the Sophist in the *Sophist* is hinted at by Proclus in his *Commentary to the Republic* 1290,7-10.

12 *The Logos/Logismos/analogio as Bond in* Meno *97d4-98a4,* Sophist *251d8-9, 253a4-c1, 268c5-d5, and* Timaeus *31c2-32a7*

Bond is the analogy, the proportion with three terms Meno.

Knowledge of the diameter a to the side b of a square is the knowledge of the infinite anthyphairesis Anth(a, b) = [1, period(2)].

12.1. *The True Opinion is transformed into Knowledge, with the addition of* ***"causal logismos" (logisms aitias)***, acting as ***bond (desmos)*** *on True Opinion* Meno 97d4-98a4.

Socrates Well, do you know why it is that you wonder, or shall I tell you?
Meno Please tell me.
Socrates It is because you have not observed with attention *the sculptures of Daedalus.* But perhaps there are none in your country.
Meno What is the point of your remark?
Socrates That if they are *not fastened* up *(me dedemena, 97d9)* they play truant and run away; but, if *fastened (dedemena, 97d10),* they stay (paramenei) where they are.
Meno Well, what of that?
Socrates To possess one of his works which is let loose (lelumenon) does not count for much in value; it will not stay with you any more than a runaway slave: but when *fastened up (dedemenon, 97e4)* it is worth a great deal, for his productions are very fine things.
And to what am I referring in all this? To *the true opinions (tas doxas tas alretheis).* For these, so long as *the true opinions (hai doxai hai aletheis)* stay with us, are a fine possession, and affect all that is good; but they do not care to stay for long, *and run away out* of the human soul, and thus are of no great value until one *binds (desei, 98a3)* them *using causal "logismos"* (*desei logismoi aitias).* 97d4-98a4

The True Opinion becomes knowledge if provided with a bond, a tie. This bond is described as *logismos aitias, causal logismos*, a crucial but as yet unclear description, related, however, to the *Logos* in the earlier *Meno* passage 86b5-c3. It needs to be carefully interpreted.

12.2. *Knowledge, just obtained as True Opinion plus the* ***bond Logismos/Logos*** *(section 12.1), is Recollection.* Meno 98a4-b6

And *this process (touto)*, friend Meno, is *recollection (anamnesis)*,
as in our previous talk, we have agreed.
But when once they are *fastened (dethosin, 98a5),*
in the first place they turn into *knowledge*, and in the second, are *constant (monimoi).*
And this is why *knowledge* (episteme) is more prized than *right opinion (orthes doxes):*
Knowledge transcends *right opinion* by the *bond (desmoi,98a8).*
Meno Upon my word, Socrates, it seems to be very much as you say.
Socrates And, indeed I set *logos (lego)* as one who does not know but only conjectures:
yet that there is a difference between right opinion (orthe doxa) and knowledge (episteme) is not at all a conjecture with me but something I would particularly assert that I knew: there are not many things of which I would say that,
but this one, at any rate, I will include among those that I know.
Meno Yes, and you are right, Socrates, in setting "logos" (legeis). 98a4-b6

Thus Knowledge and Recollection are acquired from True Opinion by the addition of the bond, an entity described as *causal logismos*, previously as *logos*. In the two passages in the *Meno* 97d-98b, the role of the *logismos/logos* is repeatedly described as that of a *bond.* We will look carefully into the precise meaning of bond.

12.3. *Interpretation of "logismos aitias" Logismos aitias 98a4 by earlier scholars*
J. Klein (1965):

All that is applicable to "true opinions." For they, too, are a possession to be highly treasured as long as they stay put: they make for all that is good and beneficent (panta tagatha ergazontai). Unfortunately, they by themselves do not want to stay for any length of time but run out of the human soul. Thus they are not worth very much until one "binds" them. This binding consists in finding *reasons for them in one's own thinking (aitias logismoi).*

Nehamas (1985):

True beliefs, he claims, like Daedalus' statues, are always escaping from the soul. But when they are bound down by *an 'account of the explanation'*, which, 'as we earlier agreed is recollection (98a3-5), they are transformed into episteme and become permanent. p.7

The former, he says, 'is worth little until it is tied down by reasoning about the explanation'(98a3-4). And it is this (touto, 98a4), he continues, that, 'as we agreed earlier, is recollection' (98a4-5). But the *aitias logismos*, as far as I can see, corresponds to nothing at the first stages of the slave's interrogation. The only process to which it can be connected is the repeated questioning that will eventually lead to the recovery of *episteme* (85c-d) p. 22

What brings about the *aitias logismos* and transforms *doxa* into *episteme* is not a new operation, additional to the eliciting of true *doxa* but rather the eliciting of enough true doxa about the subject to make having them *constitute* the *aitias logismos*. The very same true beliefs the slave now has, Socrates claims at 86a7-8, having been aroused by questioning, become knowledge (*epistemai*). . . . Plato does not explain how this transformation is to occur, and it is very difficult to know what is involved in the transition. p. 22–23.

The *aitias logismos* and recollection, strictly speaking, consists in this ability, which transcends merely having answers to different questions. . .

Waterfield (2005):

What am I getting at? I mean this to be an analogy for true beliefs. As long as they stay put, true beliefs too constitute a thing of beauty and do nothing but good. The problem is that they tend not to stay for long; they escape from the human soul and this reduces their value unless they're anchored by *working out the reason*. p. 139

Ebert (2007):

So true belief has to be bound by the "reckoning of the reason" (aitia logismou) (98a3-4). And Socrates continues: "This is, Meno my friend, recollection as was agreed between us earlier on." (98a4-5). Now this certainly does not support the idea that what we learn whenever we learn something comes to us by recollection. The passage Socrates seems to refer to here is 85c9-d1; there it has been agreed that a true belief like the one now engendered in the slave boy can be turned into knowledge by further questioning, what one has to add is the fact that by this process of questioning the reason for the geometrical theorem will be found. p. 198

Sedley and Long (2011)

> For true opinions are also a thing of beauty, as long as they stay with one, and all their consequences are good. But they're not prepared to stay with one for long. Instead, they run away from the person's soul. As a result, they are not worth very much until someone ties them down *by reasoning out the cause*. p. 37

Fine (2021):

> Another reason to think that Plato is defining knowledge is that, in the *Theaetetus*,
> 'knowledge is true belief plus a logos'
> is suggested as an answer to the question 'What is knowledge?'
> One might, to be sure, argue that
> 'knowledge is true belief plus a logos'
> is not equivalent to
> 'knowledge is true belief tied down with an aitias logismos.'
> Be that as it may, the two claims are similar enough in shape or form for it to be reasonable to think that, since the former is explicitly offered as an answer to the question 'What is knowledge?' the latter is also intended to answer it. p. 74

Roughly speaking, Fine accepts that *logos* and *logismos* in the *Meno* have essentially the same meaning. Thus, in this passage, Plato comes very close to the statement that Knowledge of the diameter to the side of a square may be achieved by true opinion plus Logos.

> Although our discussion so far leaves many questions unanswered, it at least suggests that a good translation of *aitias logismos* is: '*reasoning about the explanation*.' Plato's claim is then that to know that p is (a) to have the true belief that p and (b) for that true belief to be bound by reasoning about the aitia of p. That is, for one's true belief that p to constitute knowledge that p, one must bind it properly by being able to explain why p is so. p. 79

Fine renders *logismos aitias* as *reasoning (logismos) about the explanation (aitia).*

The phrase has been translated in many ways. Indeed, some authors (including myself in 'Inquiry in the Meno') use more than one translation, without comment. Among the translations I have seen are the following:

> 'by a chain of *causal reasoning*' (Thompson, *The Meno of Plato*);
> 'by *calculation of cause*' (Bluck, *Plato's Meno*; Sedley, '*Three Platonist Interpretations of the Theaetetus*,' has '*by calculation of the cause*');
> 'the *calculation of the reason*' (Vlastos, '*Anamnesis*');
> '*working out the explanation*' (Burnyeat, '*Socrates and the Jury*'; R. W. Sharples, *Plato: Meno* (Warminster: Aris and Phillips, 1985));
> '*reasoning out the explanation*' (Nehamas, '*Meno's Paradox*');
> '*reasoning about the explanation*' (Nehamas, '*Meno's Paradox*');
> '*account of the explanation*' (Nehamas, '*Meno's Paradox*'). p. 79

Thus, *logismos* is variously rendered as *reasoning, calculation, or account*, while *aitia* as *cause, explanation, or even reason.*

12.4. *The* ***circular/revolutionary*** *meaning of* ***bond*** **(desmos)** in the Republic 616 b7-c5

We first consider the use of the term *bond (desmos)* in the *Republic* 616b-c:

> and they saw there at the middle of the light the extremities of its *bonds (desmon)* stretched (tetamena) from heaven; or this light was *the bond (sundesmon)* of the heavens like the undergirders (hupozomata) of triremes (trieron), holding together in like manner the entire revolving vault (periphoran). And from the extremities was stretched the spindle (atrakton) of Necessity, through which all the orbits revolve (periphoras).
> *Republic* 616 b7-c5

It follows from the *Republic* 616b-c passage that for Plato a *bond* is something that holds the parts of an entity together, in order that a circular revolution in that entity may take place. The elaborate circular motions of the stars in heaven, comprising a variation of the Pythagorean Harmony of the Spheres, are held together using *light (phos)*, acting as a bond; more down to earth, Plato employs the striking metaphor of the cyclical revolutions of the oars of a moving trireme, held together in unison by the *undergirders* of the trireme acting as the firm bond.

12.5. *The* ***bond*** *268d5, formed by the intertwining (sumploken) of the names (onomaton), described in the summary 268c5-d5 of the definition of the Sophist by the method of Name and Logos, examined in Section 11.7, is the* ***Logos Criterion****, holding together the periodic anthyphairesis by which the* Sophist *is defined.*

Next, we examine the *bond (268c5)* described in the summary 268c-d and note that its function is, as the function of the bond described in the *Republic* 616b-c, to hold together a revolutionary process, namely a periodic anthyphairesis.

Sophist 268c5-d5

ΞΕ. Οὐκοῦν ***συνδήσομεν*** αὐτοῦ, καθάπερ ἔμπροσθεν, ***τοὔνομα συμπλέξαντες*** ἀπὸ τελευτῆς C7 ἐπ᾽ ἀρχήν G; ΘΕΑΙ. Πάνυ μὲν οὖν.		
ΞΕ. Τὸ δὴ τῆς ἐναντιοποιολογικῆς C7		
	εἰρωνικοῦ μέρους C6	
		τῆς δοξαστικῆς C5
μιμητικόν C4,		
	τοῦ φανταστικοῦ γένους C3	
		ἀπὸ τῆς εἰδωλοποιικῆς C2

(continued)

οὐ θεῖον D1ἀλλ' ἀνθρωπικὸν C1 τῆς ποιήσεως G
ἀφωρισμένον ***ἐν λόγοις***
τὸ θαυματοποιικὸν μόριον C7,
"ταύτης τῆς γενεᾶς τε καὶ αἵματος" ὃς ἂν φῇ ***τὸν ὄντως σοφιστὴν*** C7 εἶναι τἀληθέστατα, ὡς ἔοικεν, ἐρεῖ. ΘΕΑΙ. Παντάπασι μὲν οὖν.

Nominative	Genitive	Genitive of Genitive
Stranger Shall we then **bind up (sundesomen, 268c5)** his **name (tounoma, 268c6)** C7, as we did before, **intertwining (sumplexantes, 268c6)** from **the end** C7 to **the beginning** G **Theaetetus** By all means.		
The juggling part, that of the art of contradiction C7,		
	of the dissembling part C6	
		of the art of opinion C5 which is part of
the imitative kind C4		
	of the fantastic class C3	
		of the image-making art C2,
and is not divine D1 but human C1, productive art G		
defined in logoi —he who says that the true sophist is of this descent and blood will, in my opinion, speak the exact truth.		

In the *Sophist* 268c5-d5, the entity in question is the definition of the Sophist by means of the method of Name and Logos, given in Sect. 11.

[1] Successive *names* of the Division, in the relation of heteron to heteron, have been interpreted as the remainders of an anthyphairetic Division, starting with the Genus of all productive arts G, and ending with the Sophist C7 (in the notation of Section 11.7):

$$G > D1 > C1 > D2 > C2 > D3 > C3 > D4 > C4 > D5 > C5 > D6 > C6 > D7 > C7.$$

need some bonds, and these are the logoi, intertwining/bonding successive names with each other; thus, the end name of the Sophist is fastened with the beginning name of all productive arts

[2] We next form the ratios of successive names
(*hapseis* in the second hypothesis in the *Parmenides*,
logoi in the *Theaetetus*:

> but the things composed (sugkeimena) of these are themselves *intertwined (peplektai)*,
> and so their *names are intertwined (sumplakenta)*
> and form a *logos (logon)*;
> for *the intertwining (sumploken) of names is the true Being (ousian) of logos (logou)*.
> *Theaetetus* 202b2-5

[*Note*. The classical H.N. Fowler translation renders *logon* as *rational explanation* and *reasoning*],

as in the chain below, where a * between two successive names x and y indicates the intertwining/*sumploke* x*y leading to the generation of the ratio/*logos* x/y, formed of one name x with respect to the other name y:

$$G^*D1^*C1^*D2^*C2^*D3^*C3^*D4^*C4^*D5^*C5^*D6^*C6^*D7^*C7.$$

We note that
C7 and C4 are in the Nominative case,
C6 and C3 in the Genitive of the Nominative case, and
C5 and C2 in the Genitive of the Genitive of the Nominative case,
indicating the coupling affected by the *Logos Criterion*; thus,

$$D7/C7 = D4/C4, D6/C6 = D3/C3, D5/C5 = D3/C3,$$

still further confirmation of the anthyphairetic interpretation of the Division.

We can interpret this summary as follows:

[3] In fact, Plato more likely means the end C7 not of the Division but of the period, and thus, the beginning is not the initial genus with the name G, but the genus with the name D2, from where the period starts:

$$C7^*\ D7^*\ C6^*\ D6^*\ C5^*\ D5^*\ C4^*\ D4^*\ C3^*\ D3^*\ C2^*\ D2.$$

[4] The *bond (desmos)* of the logoi formed is exactly Theaetetus' Logos Criterion, as explained in Section 11.7:

$$[[[C7^*\ D7]]]^*\ [[C6^*\ D6]]^*\ [\mathbf{C5}^*\ \mathbf{D5}]^*\ [[[C4^*\ D4]]]^*\ [[C3^*\ D3]]^*\ [\mathbf{C2}^*\ \mathbf{D2}],$$

namely

D2/C2 = D5/C5, hence D3/C3 = D6/C6 and D4/C4 = D7/C7.

[5] The *bond* functions exactly as in the *Republic* 616b-c passage, considered in Section 12.4, namely, it holds together a circular, periodic revolution, namely, as we saw in Section 11, the Logos Criterion is the bond holding together the periodic anthyphairesis that defines the Sophist. Thus, the interpretation of the term *'bond'* in 268c5 is anthyphairetic.

12.6. The ***Logos acting as Bond collects*** *the parts generated by the dyad Being, not-Being* ***into the same/tauton*** (Sophist 253a4-c1, 251d8-9) and thus **equalizing** them (257a-e)

It follows from the *Sophist* 253a4-12, b8-c1 that, as *the vowels* (253a4) are the *bonds* (desmos, 253a5) possessing the power (dunata, 253a8) to make letters (grammata, 253a1) communicate (koinonein, 253a8) other to other (heteron heteroi, 253a6), in the same way, *the logoi* (253b10) are the *bonds*, possessing the power to make genera (gene, 253b8) communicate other to other, explained earlier (*251d8*) to mean *to collect the genera in the same/tauton*, (*eis tauton sunagagomen*), more explicitly to *equalize the Being part and the not-Being* part (*257a-e*).

This collection into the same/one and the equalization in the *Sophist* have anthyphairetic content, as follows from our analysis and interpretation of the corresponding equalization of the parts One and Being in the second hypothesis of the *Parmenides*, using the anthyphairetic circularity/periodicity of the "hapseis"/ contacts, exactly the Logos Criterion, as analyzed by Negrepontis (2024).

12.7. *Analogio is the most beautiful bond in the* Timaeus 31c2-32a7

The anthyphairetic interpretations of the collection into the same and equalization using Logos acting as a Bond in the Sophist *forces an anthyphairetic interpretation of* ***the most beautiful bond (kallistos desmos)*** *in the* Timaeus*, a proportion (analogio) with three terms x/y = y/z, collected into the same/into one.*

> And *the fairest (kallistos) of* ***bonds (desmon)*** is *that which most perfectly collects into one itself and the things which it binds together (sundoumena)*; and to effect this in the fairest manner is *the natural property of* ***proportion (analogio)***. For whenever the middle term of any three numbers, *or volumes (ogkon) or powers (dunameon)*, is such that as the first term is to it, so is it to the last term, and again, conversely, as the last term is to the middle, so is the middle to the first, then the middle term becomes, in turn, the first and the last, while the first and last become in turn middle terms, and the necessary consequence will be that all the terms are *the same (ta auta)*, and being *the same (ta auta) they all are one (hen panta estai). Timaeus* 31c2-32a7 [Translated by W.R.M. Lamb, with modifications by the author.]

The most beautiful *bond* (desmos) in the *Timaeus* 31c2-32a7

(a) Is a *bond*
(b) Is *a proportion (analogio)* in three terms of the form x/y = y/z
(c) Possesses the power to *collect* the terms x, y, and z into the same/one

Since it is a bond (a), we expect (by the *Republic* passage, Section 12.4) that it holds together a revolutionary/circular process, since it possesses the power to collect (c) and has the form of a proportion (c), we expect (by the *Sophist*'s passages, Sections 12.5,6) that it be the Logos Criterion for some periodic anthyphairesis. In fact, the Logos Criterion $b/c_1 = c_1/c_2$ in the calculation of the anthyphairesis of the diameter to the side of a square (Proposition 2.5) ideally fits with all three conditions.

12.8. *The Knowledge of the diameter* a to the side b of a square in the Meno 80d-86c and 97a-98b is True Opinion plus Logos, namely the infinite anthyphairesis of a to b

Anth(a,b) = [1, period(2)], while
the Logos $b/c_1 = c_1/c_2$

(a) is a bond (according to Section 11.7), and
(b) provides full Knowledge of the diameter to the side of a square when added to the True Opinion of the diameter to the side of a square (according to Proposition 1.5)

We have shown that the Knowledge of the line a that duplicates the square of a given line b in the *Meno* is the knowledge of the complete infinite anthyphairesis of the diameter a to the side b of a square; and that this Knowledge is achieved by first obtaining the two initial steps of the anthyphairesis of the duplicating line a with respect to b, a *True Opinion*, and then showing Theaetetus' *Logos* Criterion. Thus, it is fully confirmed that Plato's philosophical discussion on Knowledge in the *Meno* 80d5-86c3 and 97a9-98b6 passages follows closely and has as a model our reconstruction of Theaetetus' geometrical computation of the anthyphairesis of the diameter to the side of a square (in Section 2).

13 *Knowledge as Recollection in the* Meno *and the whole of Plato's work*

13.1. *Our anthyphairetic interpretation of philosophical Knowledge* as *Recollection* in the Meno is a reference to the Repetition of Logos using which the Theaetetus' Logos criterion establishes anthyphairetic periodicity and Knowledge of every dyad of lines commensurable in square only and of every intelligible Being.

The Knowledge obtained in the *Meno* 80d-86c and 97a-98b is described, not only as True Opinion and Logos but also as Recollection. But why such a proportion is called recollection/anamnesis? To understand in what sense the knowledge of the infinite anthyphairesis of the diameter to the side of a square may reasonably be described as Recollection, it is helpful to note that, as it is stressed both in Plato's *Epinomis* and in Proclus *Comments to Euclid*, *Recollection* is specifically *Recollection of Logoi*.

13.2.1. *According to the* Epinomis *977b-c, Recollection is specifically Recollection of Logoi*

> Moreover, turning back some little way,
> let us *recollect (anamnesthomen) the logoi* (*tois logois*, 977b9-c1)

13.2.2. *According to Proclus,* Comments to Euclid *44,25-47,8, Knowledge (episteme) is Recollection (Anamnesis) of Logoi*

> According to the tradition, the Pythagoreans recognized that everything we call *learning (mathesis)* is *recollection (anamnesis), not* something placed in the mind from without, like

> the images of sense pictured in the imagination, *nor* transitory (episodeiodes), like *the knowledge of true opinion (doxastike gnosis), but*, though *awakened (anegeiromene)* by sense-perception, [learning] has its source *within us*, by *the dianoia returning (epistrephomenes) to itself.*
>
> They realized too that, although evidence of such *recollections (anamneseis)* can be seen in many areas, it is especially evident in *mathematics*, as *Plato* also remarks. 'If you guide a person to the *geometric diagrams (diagrammata)*, he says, "then you can show most clearly that *leaming (mathesis) is recollection (anamnesis).*" This is why *Socrates in the Meno* uses this kind of argument to prove that *learning is* nothing but the soul's *recollecting (anamimneskesthai) its own logoi (ton heautes logon) 45,5-21*
>
> This, then, is what *learning (mathesis)* is, *recollection (anamnesis)* of *the* eternal *logoi (ton logon) in the soul;* and this is why the study that especially brings us *the recollections (tas anamneseis) of these logoi (tas ekeinon ton logon) is called the science concerned with learning/mathematics.*·46,15-18
>
> [Translations by Morrow (1970), with modifications by the author.]

13.3. *Our anthyphairetic interpretation of Recollection in the* Meno.

Proclus, in the passage cited above, provides a further hint: the mind acquires knowledge by returning to itself, thus strongly suggesting the periodicity of the ratios/logoi, using which, namely using the Logos Criterion, Knowledge is indeed acquired:

> *[μάθησις]* προβαλλομένη δὲ ἔνδοθεν ἀπ' αὐτῆς τῆς διανοίας εἰς ἑαυτὴν ἐπιστρεφομένης, [learning] has its source *within us*, by *the dianoia returning to itself.*

It is then clear that Recollection is simply the repetition of the second ratio/Logos, which indeed provides, according to Theaetetrus' Logos Criterion, full knowledge of the anthyphairesis of the diameter to the side of a square. Thus, Recollection is a *poetic reformulation* of Theaetetus' Logos Criterion.

13.4. *In all previous interpretations of Plato's theory of Knowledge as Recollection, there is no correlation of Recollection with the Theaetetus' Logos Criterion for anthyphairetic periodicity.*

Landry (2012):

> A recurring question about Plato's Meno is: what is the status and role of recollection? For philosophers of mathematics, in particular, this is an important question. Typically, and *more often dismissively*, recollection is offered up as *the platonist's 'mysterious' method, akin to intuition*, whereby we come to grasp both mathematical objects and philosophical Forms (see [Shapiro 2000]).
>
> In the more general philosophical literature, we find three detailed responses to this question.
>
> In line with the typical interpretation noted above, Guthrie [1956], Benson [1990], and Scott [2009] argue that we ought to take recollection as a method for knowledge and interpret the slave-boy situation as, respectively, an experiment in, or demonstration of, this method.
>
> On the other hand, Sternfeld and Zyskind [1986] suggest that *recollection be taken as a mere myth* that Socrates uses to motivate inquiry.

> Against both of these interpretations, Moravcsik [1971] claims that, whereas Plato intended recollection to be an a priori truth, we ought to view it as lying *somewhere between a very general empirical theory about the structure of the mind and a metaphor for how we learn*.

Shapiro (2000):

> The Meno suggests another epistemology. There, Plato has Socrates lead a slave to the theorem that the square on the diagonal of a given square is double the area of the original square. Socrates emphasizes that neither he nor anyone else taught the theorem to the slave. By asking carefully chosen questions, and pointing to aspects of a drawn diagram, Socrates gets the slave to discover the theorem for himself.
>
> Plato uses the experiment to support a doctrine that when it comes to geometry—or the world of Being generally—what is called 'learning' is actually remembering from a past life, presumably a time when the soul had direct access to the world of Being. Scholars disagree on the nature and role of this *'recollection'* in Plato's epistemology, *and most subsequent Platonists demur from it*. In any case, Plato did hold that the soul is in a third ontological category, with the ability to apprehend both the world of Being and the world of Becoming. With or without *the 'mystical' elements of the epistemology*, one gets the impression from the dialogues that the physical world is constructed as it is just so that we will be driven beyond our senses to investigate the world of Being. For Plato, mathematics is a key step in this process. It elevates the soul, reaching beyond the material world to the eternal world of Being. p. 52

Moravscik (1971):

> Important philosophic theses often have the disturbing character of falling somewhere between the areas of apriori propositions, empirical theories, and mere metaphors. One such thesis is Plato's proposal, expounded most fuHy in Meno 80D-86C, that learning of a certain kind is recollection. p. 53
>
> As a hypothesis about the structure of the mind, the recollection thesis seems to fall between being a very general empirical theory and being a metaphor. The reason for this is the inherent vagueness of the thesis. p. 69

13.5. *Meno's Knowledge as Recollection is most valuable for understanding the anthyphairetic structure of Plato's intelligible Being.*

We observe that Plato takes great interest to describe in philosophical terms the geometric knowledge of the anthyphairesis of the diameter to the side of a square. Furthermore, we can understand Plato's philosophical interest in this special case of geometric knowledge, since we have seen (in Sections 11 and 12) that in the *Sophist* Plato's intelligible Being is a philosophical imitation of a dyad of geometric lines having an anthyphairesis that satisfies Theaetetus' Logos Criterion and is thus in periodic anthyphairesis. Thus in effect, *Meno*'s theory of Knowledge as True Opinion plus Logos and as Recollection can be considered as a revealing introduction to Plato's theory of Knowledge of an intelligible Being.

The anthyphairetic nature of the philosophic term *True Opinion* in the *Meno* for a geometrical problem has implications for the use of the term True Opinion in purely philosophic dialogues, such as *Symposium*, *Republic, Timaeus Parmenides's* second hypothesis, *Theaetetus*, *Sophist*.

Thus in the *Symposium,* the Knowledge of a true Intelligible Being is given in terms of True Opinion plus Logos, exactly as in the *Meno*; in the *Republic* True Opinion, an initial segment of the philosophic anthyphairesis of an intelligible Being equals the full knowledge of a sensible participating in the intelligible being, something that is modified in the *Timaeus*, with the introduction of the Receptacle (as studied in the work by Negrepontis and Kalisperi 2023).

In particular, the Knowledge of an intelligible Being can have such an anthyphairetic description only if it is a dyad in the philosophic analogue of periodic anthyphairesis, something that is fully confirmed independently in the cases of the One, completed to the periodic anthyphairetic dyad One, Being of the second hypothesis in the *Parmenides* (Negrepontis 2024) and of the Being, completed to the periodic anthyphairetic dyad Being, not-Being in the *Sophist* (Negrepontis in preparation).

The following diagram shows in simplified form the various equivalent descriptions of Knowledge (episteme) of intelligible Beings in Plato's work.

Knowledge (episteme) in Plato				
Recollection	True Opinion +Logos	Name +Logos	Division in Kinds	Division +Collection
Meno 80d5-86c3, 97a9-98b6	*Meno* 80d5-86c3, 97a9-98b6

14 Summary

Plato sets out to explain his philosophical notion of Knowledge in the *Meno*, by explaining what he means by Knowledge in the concrete geometrical case of the diameter to the side of a square. For that purpose, Plato introduces the concepts of True Opinion and Logos/Logismos and formulates his answer as follows: the Knowledge of the diameter a to the side b of a square is True Opinion plus Logos/Logismos.

Our interpretation

of *True Opinion* is that it consists of the first two anthyphairetic relations of the diameter to the side of a square,

of *Logos* is the Theaetetus' Logos Criterion for periodic anthyphairesis,

of *Knowledge* is the knowledge of the infinite anthyphairesis of the diameter to the side of a square, obtained formally as True opinion plus Logos, and

of *Recollection* is a (poetic) reformulation of the repetition of the Logos/ratio, resulting in the complete knowledge of the diameter to the side of a square.

The Mystery of Plato's Receptacle in the *Timaeus* Resolved

Stelios Negrepontis and Demetra Kalisperi

Dedicated with admiration

ὁ δὲ [Θεαίτητος] οὕτω λείως τε καὶ ἀπταίστως καὶ ἀνυσίμως ἔρχεται ἐπὶ τὰς μαθήσεις τε καὶ ζητήσεις μετὰ πολλῆς πρᾳότητος,
οἷον ἐλαίου ῥεῦμα ἀψοφητὶ ῥέοντος,
ὥστε θαυμάσαι τὸ τηλικοῦτον ὄντα οὕτως ταῦτα διαπράττεσθαι.
But [Theaetetus] advances toward mathematics (τὰς μαθήσεις) and research (ζητήσεις) smoothly and surely and successfully (λείως τε καὶ ἀπταίστως καὶ ἀνυσίμως), with perfect gentleness, like a stream of oil that flows silently (οἷον ἐλαίου ῥεῦμα ἀψοφητὶ ῥέοντος), so that one marvels (θαυμάσαι) how he accomplishes all this at his age (τὸ τηλικοῦτον ὄντα). Theaetetus 144b3-7.

Abstract

Plato, most unexpectedly, in the middle of the *Timaeus* (48e2-49a7) declares that the sensible bodies cannot be explained solely by their participation in the intelligible, as we were led to believe by reading the long succession of all his previous dialogues, but that it is now *necessary* to introduce, beside the intelligibles and the sensibles, a Third Kind, the *Receptacle*.

We must, however, in beginning our fresh account of the Universe make more distinctions than we did before; for whereas then we distinguished two Kinds (τότε μὲν γὰρ δύο εἴδη διειλόμεθα), we must now declare another *Third Kind* (τρίτον ἄλλο γένος). For our *former exposition*, those two were sufficient, one of them being assumed as a *Paradigm* (παραδείγματος εἶδος), intelligible, and always self-similar Beings (νοητὸν καὶ ἀεὶ κατὰ ταὐτὰ ὄν), and the second as *the Paradigm's Image* (μίμημα δὲ παραδείγματος), subject to generation and visible (γένεσιν ἔχον καὶ ὁρατόν). A *Third Kind* we did not at that time

distinguish, considering that those two were sufficient, but now the argument seems *to compel us* (ἔοικεν *εἰσαναγκάζειν*) to try to reveal by words a Kind that is baffling and obscure (χαλεπὸν καὶ ἀμυδρὸν εἶδος). What essential property, then, are we to conceive it to possess? This in particular – that it should be *the receptacle* (ὑποδοχὴν), and as it were *the nurse of all Generation* (πάσης εἶναι γενέσεως αὐτὴν οἷον τιθήνην).Yet true though this statement is, we need to describe it more plainly 48e2-49a7.
(Emphasis by italics or bold here and in future occurences is ours)

It is fair to state that both the reason that Plato felt compelled to introduce the Third Kind and its nature have so far eluded understanding and remained a mystery, and this is certainly not because of any lack in efforts.

In the present work, we aim to obtain a new and, we believe, definitive understanding of the nature of the Receptacle and of the reason that Plato felt obliged to introduce it. This resolution is possible only because we have uncovered, under Plato's fascinating account, the well-hidden deep Mathematics of incommensurability and of infinite anthyphairesis, some going back to the Pythagoreans, some discovered recently by Theaetetus, the great resident mathematician of the Academy, and which are fundamental, not only for Plato's philosophical system of the unchanging intelligible Beings, but also for his ambitious description of the incessantly changing sensible, physical World, as well. Without reaching an understanding of the underlying Mathematics, it is impossible to gain any true understanding of the philosophy based on it; it is very much like trying to understand Newtonian physics without calculus or quantum physics without Hilbert space operators.

The starting point of our work is the interpretation of the intelligible Being as the philosophical analogue of a dyad in periodic anthyphairesis, and the pre-*Timaeus* interpretation of a sensible body participating in the intelligible, in terms of an initial finite segment of the infinite intelligible anthyphairesis. The serious problem that results from the built-in intelligible anthyphairetic *infinity* is that this infinity leads to the formation of *infinite kosmoi*, a problem akin to the intelligible Third Man Argument; it has not been realized that the *sole* reason for the necessity of introducing the Third Kind in the *Timaeus* is the necessity to avoid infinite kosmoi. At this point, it must be emphasized that the intelligibility is neutral on this problem, its only necessary condition being that the intelligible must retain the control of the sensibles, whether these sensibles live in infinitely many kosmoi or in one kosmos.

Plato attempts to deal with the problem, by eliminating the infinite multitude of anthyphairetic remainders, replacing them by the mathematically equivalent tight double inequalities and generalized side and diameter numbers (the "convergents" of modern continued fractions), which are vividly and aptly described, in order to represent every sensible body, as a dyad consisting of Content & Receptacle, but he realizes that such arithmetical methods, while they work perfectly well for the geometric anthyphairetic remainders, fail to make sense for the intelligible philosophical analogues of the geometric anthyphairetic remainders.

It is precisely because of this differentiation that Plato finds it necessary to introduce the geometric Third Kind; it consists of the *four primary bodies*, each identified with one of the surfaces of the *four* (minus the 12hedron) *canonical solids*, *primary earth* PE/cube, *primary water* PW/20hedron, *primary air*

PA/8hedron, *primary fire* PF/pyramid, studied in the Theaetetean Book XIII of Euclid's *Elements*. The *comprehension of the canonical solids in the sphere*, a central theme in Book XIII, in fact the world sphere in Plato's mind, provides several crucial advantages for this choice, to wit:

(a) It makes possible the *canonical comparison* by which the primary earth PE turns to be *incommensurable*, in fact in periodic anthyphairesis to each of the other three, mutually commensurable, primary bodies, and thus allows for the *substitution* of the intelligible dyad <intelligible earth, intelligible fire> by the Third Kind dyad <PE, PW> in its role of generating and being the *cause* of the sensible bodies and their motions.
(b) ("*intelligence*") It makes possible the *participation*, via the Soul of the World, of the Third Kind into the intelligible, thus turning the Third Kind into a "*bastard intelligible*" and salvaging Plato's absolutely essential philosophical requirement that the intelligible governs over the sensibles (by means of True Opinion).
(c) ("*necessity*") It entraps and imprisons the Third Kind in the World sphere, not allowing the generation of infinitely many remainders and Kosmoi above and beyond the initial one, but turning, equivalently, the participation into sensible dyads, vividly and accurately described as having the form Content & Receptacle, underlying the tight remainder-free double inequalities and anthyphairetic "convergents," thus saving *the One Kosmos* with the traditional four (not elements any more, but) derived kinds.

Introduction

Plato's theory of intelligible Beings, or Ideas, is systematically presented in the *Parmenides*, *Sophistes*, and *Politicus* and is present in all platonic dialogues, including the *Politeia*, *Phaedo*, *Meno*, *Sumposion*, and *Theaetetus*. According to the interpretation of Plato's philosophy given by Negrepontis 2012, 2018, 2019, TA, an intelligible Being is a dyad in a philosophic analogue of periodic, hence, infinite, anthyphairesis (its *Oneness* being secured by the equalization of the elements of the dyad by periodicity, its *periodicity* by *Logos*, and the Logos Criterion of periodicity) (Sect. 1).

Before *Timaeus*, there is no systematic treatment of the sensibles. Every sensible body participates in an intelligible Being. The full knowledge of such a sensible is obtained as a True Opinion of the intelligible Being in which it participates (*Sumposion* 210e-211a, *Politeia* 475e-480a, 509d-510b), and a True Opinion of an intelligible Being is identified with an initial finite segment of the intelligible infinite anthyphairesis (*Theaetetus* 189e-190a, *Sophistes* 264a-b) (Sect. 2).

Thus, an intelligible Being has a built-in, intrinsic *infinity, anthyphairetic infinity*, and *infinite multitudes of anthyphairetic remainders.* We claim that it is precisely this

intelligible infinity that poses *the problem of infinite kosmoi*, stated twice in the *Timaeus* (31a2-b3, 55c7-d2), and that, although usually treated by modern scholars as a peripheral and irrelevant one, this is the *central*, in fact the *sole*, problem that makes *necessary* (ἀνάγκη, 48a1, 49a3, 52b3) the introduction of the Third Kind/Receptacle (Sect. 3).

At this point, it is argued *heuristically* that Plato's "cure" (ἴαμα, in Plutarch's words) of avoiding the infinitely many anthyphairetic remainders consists in passing from an initial finite segment of the anthyphairetic division to an *equivalent* representation, in terms of some remarkable *tight double remainder-free mathematical inequalities* (generalizing the obvious equivalence of an anthyphairetic relation $a = kb + c$, in which the remainder c is present, with the double inequality $kb \leq a \leq (k + 1)b$, in which the remainder c has been eliminated). This representation is closely related to the Pythagorean side and diameter numbers, greatly extended by Theaetetus to all quadratic incommensurabilities, the precursors of the *convergents* of modern continued fractions. As we shall see in Sect. 9, the impressive tightness of these double inequalities is described vividly and validly in the *Timaeus* with the term *Receptacle* and with a variety of other terms (Sect. 4).

However, Plato realizes and explains lucidly in passages 51e6-52a4 and 52c5-d1 the *impossibility* of applying these geometrical techniques and manipulations, directly to the dyad of the pure intelligible Being. The necessary algebraic manipulations make no sense for an intelligible dyad a, b (such as the dyad One, Being in the second hypothesis in the Parmenides), for which it makes no sense to form a multiple of a, and even less sense for a to enter into, to have a included in, another multiple of b (Sect. 5).

Plato introduces *Triangle A*, which he uses to generate the surface of the cube, and *Triangle B*, which he uses to generate the surfaces of the pyramid, 8hedron, and 20hedron, thus introducing four of the five *canonical solids*, constructed in the Theaetetean Book XIII of Euclid's *Elements* (53c4-d7, 54a1-d7, 54d5-55c6) (Sect. 6); the surfaces of these bodies, simply renamed, form *the four primary bodies*, to wit primary earth PE, the surface of a cube, consisting of 24 (right angle isosceles) Triangles A, and primary fire PF, air PA, and water PW, the surface of the pyramid, 8hedron, 20hedron, consisting of 24, 48, 120 (half of the equilateral triangle) Triangles B, respectively. The introduction of these geometric bodies strongly suggests that Plato is acting in the direction of the heuristics we explained in Sect. 4, and that he introduces the *Third Kind/Receptacle* (48e2-49a7) for the *sole* reason of avoiding the infinite kosmoi. At this point, we have no indication if Plato's choice of the geometric Third Kind is a good one. *Four requirements* must be met before Plato's choice can be deemed successful.

The *first requirement* is that the primary earth PE must be *incommensurable* to, in fact in periodic anthyphairesis with, any of the other (clearly *commensurable* to each other) three primary bodies PW, PA, and PF. A dyad among the elements of the Third Kind must *replace* the intelligible dyad in its role of generating the sensibles – and for this certainly infinite anthyphairesis is necessary. Plato clearly hints at their incommensurability in 54b5-d3, 56d1-6, but does not explain how this comes about. For this to happen, Triangle A and Triangle B must be *incommensurable,* in fact in periodic anthyphairesis. We show that there is a *canonical way* of comparing these triangles, the following: We regard Triangle A as half of the face of a cube,

Triangle B as half of the face of a pyramid, and we comprehend this cube and this pyramid in the same sphere. It is shown with the help of careful computations mostly carried out in Propositions 13, 15, and 18 of Book XIII of the *Elements*, and with the help of Theaetetus' theorem on the periodicity of the anthyphairesis of quadratic irrationals, that indeed any multiple of Triangle A is in periodic anthyphairesis with any multiple of Triangle B (Sect. 7).

The *second requirement*, completing the first, is that the Third Kind will generate all the sensibles and their motions, replacing the intelligible. Indeed, according to the fundamental (and ill-understood thus far) passage 57d-58a, one of the incommensurable dyads of primary bodies will be the basis for the *Third Kind*, substituting for the intelligible Being as the *cause* for the generation of all sensible bodies. Plato selects the incommensurable dyad PE, PW, with the aid of the commensurable auxiliary ratios PW/PA = 5/2 and PW/PF = 5/1; thus, a sensible body is determined by an initial finite anthyphairetic segment of the infinite anthyphairesis PE to PW. This implies that all sensible motions and generations of sensibles, including those by the Receptacle, are between dyads of primary bodies (Sect. 8).

We next present the main argument that the description of the Third Kind is equivalently given by the Receptacle and by the "diakena" of the primary bodies (an initial argument was already given just above). The argument consists in comparing the description of the generation of the *Timaeus* sensibles in terms of the "diakena" of the primary bodies with the corresponding description in terms of the Receptacle. The four steps, by means of which the generation of the sensibles and their motion takes place in and by the Receptacle, as described in the passages 50a-51a, 52d4-53a6, and 57a7-c6, are so uncannily similar to the four steps, by means of which the generation of the sensibles and their motion takes place in and by the "diakena" of the primary bodies, as described in the passages 58a4-c2, 61a7-b3, that the conclusion, that the Receptacle and the primary bodies are equivalent descriptions of the Third Kind, is inescapable. The same argument both makes clear the mathematical origin of the term Receptacle (as a reflection of the double tight inequalities) and leads to the satisfaction of the *third requirement*, namely the fact that the description of the sensibles in terms of the Third Kind does indeed succeed in eliminating the infinite remainders and Kosmoi, securing a One Kosmos. But we still have not pinpointed what is special with the primary bodies that makes the One Kosmos choice not simply possible, but mandatory and necessary. We will take up this issue, thus completing the third requirement, in the next section (Sect. 9).

The *fourth requirement* is that the Third Kind *participates in the intelligible*, something necessary in order to salvage the sine qua non of Plato's philosophic system, namely the domination of intelligible Beings over sensibles, namely the *participation of these modified sensibles in the intelligible.* This is achieved with (a) the participation of the Soul of the World into the intelligible (with the sphericity of the World 33a6-b5, and the revolutions of the Soul 36d8-e5, imitating intelligible periodicity), and (b) the *comprehension* of the primary bodies in the sphere, as shown in the second part of Propositions 13–16 of the Theaetetian Book XIII of the *Elements*.

With the fourth requirement satisfied, the Third Kind does indeed assume (paraphrasing somewhat 52b1-2) the status of a *"bastard intelligible"* entity, of an

entity which, though far removed from the intelligible nevertheless, *participates* in the intelligible Being in a most perplexing ("δυσαλωτότατον," 51a7-b1) manner, a *special* geometric dyad in periodic anthyphairesis, that substitutes the intelligible in the role of being the cause and generator of the sensible bodies and of their motions.

We still need to *satisfy the third requirement*. A geometric dyad in periodic anthyphairesis is equally capable of generating either remainders and infinite kosmoi, like the intelligible, or remainder-free dyads of the form Receptacle & Content. We have seen in Sects. 8 and, especially, 9 that the primary bodies, and specifically the dyad PE, PW, do indeed generate sensibles in the desired Receptacle & Content form, leading to One kosmos. But we have not yet pinpointed the reason that this desired form is achieved. This is indeed achieved again by the *comprehension* of the primary bodies *in the sphere*. According to passage 58a4-7, the resulting confinement, imprisonment, and entrapment of the primary bodies into the spherical Soul of the World results in the inability of the Third Kind to employ the transmitted, participated intelligible anthyphairetic information for the generation of many, potentially infinite anthyphairetic remainders and kosmoi, and the *necessity* to generate instead sensible bodies of the form Content & Receptacle, by the filling and tightening of the small primary body into the great primary body (Sect. 10).

We are now, at long last, able to describe fully the nature and the structure of the *Timaeus* sensibles: The sensibles participate in the intelligible via the Third Kind, every sensible is a syllable of the form Receptacle & Content, and there are four kinds of sensibles in One Kosmos.

Sensible water or earth is defined in terms of a "convergent" M_n/N_n of the dyad PE, PW; for odd index, the "convergent" satisfies the Content & Receptacle type of inequality $M_{2n-1}PW < N_{2n-1}PE < (M_{2n-1} + 1)PW$, and thus the defeated PE becomes dissimilar to itself, *dispersed* by and similar to the victorious PW, and the whole dyad is a *waterlike sensible body,* while for even index the "convergent" satisfies the Content & Receptacle $(M_{2n} - 1)PE < N_{2n}PW < M_{2n}PE$, and thus the defeated PW becomes dissimilar to itself, *consolidated* by and similar to the victorious PE, and the whole dyad is an *earthlike sensible body.* For sensible air or fire, we must consider the triad PA or PF, PW, and PE, instead, in which the masses of primary air PA or primary fire PF enter and fill the "diakena" of the masses of primary water PW, which have already filled the "diakena" of the masses of primary earth PE. With this stratagem,[1] the One World with four kinds of sensible bodies is now finally achieved (Sect. 11).

The essential correctness of our interpretation is further confirmed by the fully satisfying answers it can provide for a host of *questions* that up to now had no satisfactory answer or no answer at all:

[1]. The reason for stating in the first place in 31a-b, and for reopening the *"infinite kosmoi"* question at 55c-d

[2]. The reason why Plato defines the primary bodies as the *surface*, rather than the volume, as it would have been more natural, of the four regular solids

[1] From Greek στρατήγημα; the official spelling "stratagem" does not appear correct.

[3]. In which way primary earth and primary fire are *incommensurable*, as hinted but not explained by Plato
[4]. The necessity of incommensurability of the primary earth to the other three primary bodies and the crucial importance of passage 57d-58a, particularly the meaning of *Inequality*, in understanding the construction of the Third Kind
[5]. *"Diakena," first* occurring in 58b5, replace and are identical with *Receptacle last* occurring in 57c3
[6]. The filling of the Receptacle and the "diakena" "fully" "so that not even one part is left out" is a vivid description of the Mathematics of infinite anthyphairesis (modern "convergents" of continued fractions)
[7]. The difference between sensible *"such"* and Receptacle *"this,"* 49e7-50a2
[8]. Every sensible participating in the intelligible Being with dyad F, notF, is *sometimes F, sometimes notF*, a puzzling earlier description of the sensibles (*Sumposion* 210e-211a, *Politeia* 475e-480a), explained in terms of *Dispersion and Consolidation*
[9]. The reason that the Universe does not lapse into eternal Rest, but will *keep moving incessantly*, is intimately related with the incommensurability and the participation of the *"bastard intelligible"* entity into the intelligible, by means of being *comprehended* in the Sphere, 58a2-7, c2-4.

In fact, the *Timaeus* is an intellectual triumph, because it represents the first attempt to explain mathematically the physical world in accordance with the experimental data available, specifically to explain the incessant motion observed in it, employing the deep mathematical achievements of his era, namely the quadratic incommensurability and periodic anthyphairesis, achieved initially by the Pythagoreans and then greatly extended by Theaetetus. It is the first instance of a long series of the "Unreasonable Effectiveness of Mathematics in Natural Sciences," an effectiveness that was enunciated as a mysterious problem by Wigner 1960, and to which an answer is being attempted, based on the Paradoxical Nature of Mathematics (Negrepontis and Farmaki 2021).

We should note that the whole platonic conception of the Receptacle in the *Timaeus* relies heavily on the deep mathematical achievements of the great mathematician Theaetetus. The main reason for the difficulties of the scholars on the *Timaeus* to reach, despite intensive study, essential understanding is that there appears to have been little appreciation of the underlying deep mathematics, especially the Mathematics of incommensurability, on which Plato's philosophic structure is founded.

Section 1 *The Platonic Theory of the Intelligible True Beings: The Philosophical Analogue of a Dyad in Periodic Anthyphairesis*

According to our interpretation, an *intelligible (Platonic true) Being* consists of a dyad of parts satisfying the *philosophical analogue of geometric periodic anthyphairesis*. The paradigmatical true Being is the One of the second hypothesis in the *Parmenides*, consisting of the dyad <One, Being> (studied in Negrepontis TA), or of the dyad <Being, Not-Being>, such as <Just, Unjust>, in the *Sophistes* and *Politicus* (studied in Negrepontis 2012, 2018), in a philosophical analogue of geometric anthyphairesis, for which the exact analogue of the Logos Criterion for periodicity holds.

1.1. *Geometric anthyphairesis*

Let us recall the *geometrical concept of anthyphairesis* of a dyad of opposite magnitudes, the greater a and the smaller b, $a > b$:

$$\begin{aligned}
&a = k_0 b + a_1, \quad \text{with } a_1 < b,\\
&b = l_0 a_1 + b_1, \quad \text{with } b_1 < a_1,\\
&\ldots\\
&a_{n-1} = k_{n-1} b_{n-1} + a_n, \text{with } a_n < b_{n-1},\\
&b_{n-1} = l_{n-1} a_n + b_n, \text{with } b_n < a_n,\\
&a_n = k_n b_n + a_{n+1}, \text{with } a_{n+1} < b_n,\\
&\ldots
\end{aligned}$$

Here

$$k_0, l_0, k_1, l_1, \ldots, k_n, l_n, \ldots,$$

denotes the sequence of successive quotients (natural numbers), and

$$a > b > a_1 > b_1 > \ldots > a_n > b_n > \ldots$$

the sequence of successive remainders (magnitudes) of the anthyphairesis of a to b.

In case a remainder never divides the immediately previous remainder, the anthyphairesis is said to be *infinite*. If the anthyphairesis of a to b is infinite, then a and b are *incommensurable* (Proposition X.2 of Euclid's *Elements*).

The anthyphairesis of a to b is *periodic* if there is an index n, such that the ratio a/b is equal to the ratio a_n/b_n (or to the ratio b_n/a_{n+1}) (*Logos Criterion* for periodicity).

1.2. *A platonic intelligible true Being is the philosophical analogue of a dyad in periodic anthyphairesis*

According to our interpretation, an intelligible Platonic true Being consists of a dyad of parts satisfying the philosophical analogue of geometric periodic anthyphairesis.

The paradigmatical true Being is the One of the second hypothesis in the *Parmenides*, consisting of the dyad < One, Being >, or the dyad < Being, Not-Being > in the *Sophistes*, in the philosophical analogue of periodic anthyphairesis. The anthyphairetic interpretation of a platonic intelligible true Being has been obtained by our analysis of the following:

- The dyad < One, Being > in the second hypothesis of the *Parmenides* 142b1-155e3, and of *Philebus* 15a-17a (Negrepontis TA)
- The Division and Collection of the Angler and the Sophist in the *Sophistes*, and of the Statesman in the *Politicus* (Negrepontis 2012, 2018)
- The dyad < beautiful, ugly > in the *Politeia* 475e9 (Negrepontis 2019)

According to this interpretation, a platonic idea is the philosophic analogue of a dyad of opposite parts; periodicity, as described in the *Parmenides* 144c2-e1, *equalizes* the two opposite and unequal elements of the dyad; thus, a platonic idea qualifies to be called a *One*, as indeed it is explained in the *Plilebus* 15a-17a. This sophisticated sense of Oneness is completely lost among scholars on Plato. Thus, e.g., Annas 1981, Chap. 9, claims that there are two classes of platonic ideas, one coming from opposites, and one not.

Thus, an intelligible Being is *a dyad a, b* of parts, in the philosophical analogue of periodic anthyphairesis. The model of an *intelligible Being* is *the dyad* a = One, b = Being in the second hypothesis of the *Parmenides*.

It is shown there that the *anthyphairesis*

$$
\begin{aligned}
&a = b + a_1, \text{with } a_1 < b, a_1 \text{ a smaller One,}\\
&b = a_1 + b_1, \text{with } b_1 < a_1, b_1, \text{a smaller Being,}\\
&\ldots\\
&a_n = b_n + a_{n+1}, \text{with } a_{n+1} < b_n,\\
&b_n = a_{n+1} + b_{n+1}, \text{with } b_{n+1} < a_{n+1},\\
&\ldots
\end{aligned}
$$

is *infinite*, and in fact *periodic*; namely, there is an index n, so that

$$a_n/b_n = a/b \ (\textit{Logos Criterion} \text{ for periodicity}).$$

1.3. *The difference between a geometrical anthyphairesis and its philosophical analogue*

For an understanding of the *Timaeus*, it is of importance to have in mind *the difference* between a geometrical anthyphairesis and its philosophical analogue.

The philosophical analogue has *no quotients*; since it makes no sense to talk about two times Beautiful or two times Ugly, it certainly makes sense to consider two times a magnitude. This difference will turn out to be crucial in Sects. 4 and 5, when we will realize that geometrical anthyphairesis can be manipulated mathematically, in ways that do not make sense and hence are not allowed for its philosophical intelligible analogue. Plato undoubtedly would regard the philosophical anthyphairesis as the pure, simple, and genuine superior entity, and the geometrical as the rather corrupted inferior one.

Section 2 *[Pre-Timaeus Sensible Bodies] A True Opinion of an intelligible Being is identified with an initial finite segment of the infinite anthyphairesis of the intelligible Being, and the Sensibles participating in an intelligible Being are fully known by a True Opinion of the intelligible Being.*

We outline our interpretation of Plato's pre-*Timaeus* theory of *sensible bodies* (Negrepontis 2012; Negrepontis and Pappa Birba TA). According to the *Timaeus*

30c-31a, there is a unique intelligible Being, identified as the dyad <IE, IF>, consisting of intelligible earth IE and intelligible fire IF, in which every sensible body *participates*. A sensible body, identified as a *"doxaston,"* is an entity whose full knowledge is a true opinion *(doxa)* of the intelligible Being (*Politeia* 475e6-480a3, 509d1-510b1), namely as a finite initial system of the *infinite anthyphairesis* of the intelligible Being (*Sumposion* 202a, 209e-211d, *Meno* 97e-98c, *Sophistes* 264a-b).

2.1. *The anthyphairetic interpretation of True Opinion ("alethes doxa"): The True Opinion of an intelligible Being is identified with an initial finite segment of the infinite anthyphairesis of the intelligible Being.*

The anthyphairetic interpretation of the intelligible Beings makes possible a deeper and more precise understanding of True Opinion. Another equivalent description of "Division and Collection" is given by "True Opinion ("alethes doxa") and Logos" in *Sumposion* 202a2-10*,* 209e5-211d1, *Meno* 97e2-98c4 (where instead of "logos" the equivalent expression "logismos aitias" is employed) and in *Theaetetus* 201c8-d3*,* 202b8-d7. Furthermore, given that "true opinion" is described as "*alogos*" in *Sumposion* 202a6, *Theaetetus* 201d1, and *Timaeus* 28a3, 51e4, "opinion" is related only to anthyphairetic division (and not at all to the Logos Criterion for anthyphairetic periodicity).

What is *that which always is (τὸ ὂν ἀεί)* and has no becoming (γένεσιν δὲ οὐκ ἔχον)?
And what is that which is *always becoming* (τὸ *γιγνόμενον* μὲν *ἀεί*)
and never is (ὂν δὲ οὐδέποτε)?
Now the one of these (τὸ μὲν) is apprehended (περιληπτόν) by means of noesis (νοήσει)
with logos (μετὰ λόγου), since it exists always (ἀεὶ κατὰ ταὐτὰ ὄν);
whereas the other (τὸ δ') is an *object of opinion (δόξῃ) alogos (ἀλόγου)*
opinable (δοξαστόν) with the aid of sensation (μετ' αἰσθήσεως),
since it becomes (γιγνόμενον) and perishes (ἀπολλύμενον)
and never really **is** (ὄντως δὲ οὐδέποτε ὄν). *Timaeus 27d6-28a4*
[the translation of all passages from Plato in this work is, unless otherwise indicated, by Plato, Translation of Plato in twelve volumes, with modifications by the authors]

On account of "opinion" being "alogos," the most natural conclusion would be to equate "true opinion" with "division." However, division is infinite, while the two descriptions of "opinion" in Plato, *Theaetetus* and *Sophistes* (*Theaetetus* 189e4-190a6, *Sophistes* 264b1, *Scholia in Eucliden* X.2, 1–6) clearly show that "opinion" is a process finite in nature.

But the soul, as *the image* presents itself to me when it thinks,
is merely conversing with itself,
asking itself questions and answering, affirming and denying.
When it has arrived at a decision (ἐπάξασα), whether slowly or with a sudden bound,
and is at last agreed, and is *not* in need of a *dichotomic decision* (μὴ διστάζῃ),
we call that its *Opinion* (δόξαν) *Theaetetus* 189e4-190a6

There is considerable backing for interpreting "διστάζῃ" as a *dichotomic decision:*

(i) Hesuchios *Lexicon*, in Delta 1976 and 2021, [distazei] is rendered as "dichonoei" (being of a mind divided in half), while in Delta 2086, "distazei" is equated with "amphidoxei" (having both opinions).
(ii) *Magnum* 278, 35–36 explains "distazein" as thinking in a double manner ("dichos bouleuesthai") or as "to have two stations in thinking" ("duo staseis echein kata dianoian").
(iii) Philoponus notes in *Comments to Aristotle's On Soul* 15,78,11-26 that judgment can be compared to "distazei," which is likened to traveling a divided road ("schisten odon"), considering to go in one or in the other direction.

Thus, "μὴ διστάζῃ" signifies a stop at an initial finite stage of the infinite intelligible anthyphairetic division.

Finally, in *Sophistes 264a9-b1* "thought is the conversation of the soul with itself, and opinion is the *final* result ('apoteleutesis') of thought."

Moreover, the *Anonymous Scholion X.2 to Euclid's Elements* describes "opinion" as the philosophical analogue of *finite anthyphairesis*. It is stated there that it is in the nature of numbers to have finite anthyphairesis,

> those [the numbers] when divided end in a definite end, unity

[cf. Propositions VII.1, 2 of the *Elements*]; this is so, the *Scholion* continues, because

> numbers act in an opinion-like manner ('tous de arithmous doxastikos'), and
> opinion is of a finite nature ('peperastai gar mallon he doxa').

It now follows, from the interpretation of division and collection, that a true opinion of an intelligible Being is the knowledge provided by a finite initial segment of the infinite anthyphairetic division of the intelligible Being.

There is of course not just one, but *an infinite multitude of true opinions*, each one corresponding to a finite initial segment of the infinite anthyphairesis of the intelligible dyad. Details can be found in Negrepontis (2012, Section 7).

2.2. *A sensible body participating in an intelligible Being is fully known by a True Opinion of that intelligible Being (Politeia 475e6-480a13)*

A sensible entity participating in an intelligible idea is generally described by Plato as an image, a copy of the intelligible Being:

> the one kind (ἐν μὲν εἶδος) being assumed (ὑποτεθέν) as a *model* (ὡς παραδείγματος), *intelligible (νοητὸν)* and always (ἀεὶ) unchangingly (κατὰ ταὐτὰ) existent (ὄν), and the second (δεύτερον) as *the model's copy*, subject to being generated and visible.
> *Timaeus* 48e3-49a1

But this is too indefinite. Since the intelligible idea has the structure of a dyad in periodic anthyphairesis, we might ask what would constitute a copy, an image, and an approximation of this idea?

From the *Politeia* 475e6-480a13 ("doxaston" 478a11, b2,b3, e3, especially 479d7), 509d1-510b1 ("doxaston" 510a9, used in the analogy of the Divided Line), 534a2-9, and the *Timaeus* 28a2-4 ("doxaston" 28a3), 28c1-2 and 51d3-7, and 51e6-52a6, we present below a condensed version of the argument in the *Politeia* 475e-480a, as reconstructed in Negrepontis and Pappa Birba TA, that a sensible body coincides with a "doxaston."

Basic Proposition in the *Politeia* 475e6-480a3. A sensible body participating in an intelligible Being is fully known by a true opinion of that intelligible Being.

Proof Let S be a sensible body participating in an intelligible Being, with dyad

$$< \mathrm{F}, \mathrm{notF} >.$$

By the crucial property of sensible bodies, S is an entity which *sometimes is F, and sometimes not F* (479a5-b2, d3-6).[2]

Hence, S is a *Being between* the intelligible Being (τοῦ εἰλικρινῶς ὄντος) with dyad <F, notF> and the absolute not-Being (τοῦ μηδαμῇ ὄντος) (477a6-8).

Hence, the complete knowledge (dunamis, 477d2) of S is a *knowledge between* ignorance and the knowledge of the intelligible Being (478e4-5).[3]

Hence, by 2.1, the complete knowledge of S is a true opinion about the intelligible Being.[4]

Hence, by definition, S is *opinable* (doxaston) with respect to the intelligible Being.[5]

[2] Exactly the same description of sensibles is also stated in the *Sumposion* 210e-211a, but in neither *Sumposion* nor *Politeia* is the inference shown or adequately explained. It is explained in the *Timaeus* 58a-c, in terms of the representation of a sensible body as a dyad Receptacle & Content either in Dispersion (and then not F) or in Consolidation (and then F), clearly an anthyphairetic property (cf. Sects. 9, 10, and 11).

[3] A *between Being corresponds* to a *between Knowledge by which it is fully known,* since

the extreme Beings correspond (ἀποδιδόντες) to the extreme Knowledges (τοῖς μὲν ἄκροις [extremes Being] τὰ ἄκρα [extremes Knowledges], and

the Between Beings to the Between Knowledges (τοῖς δὲ μεταξὺ [Between Being] τὰ μεταξὺ [Between Knowledge]) 478e4-5.

[4] A true opinion (δόξα) about an intelligible Being is a *knowledge* (about the intelligible Being) *between (μεταξὺ)* ignorance (ἀγνοίας) and intelligible knowledge (episteme, γνώσεως). 478c13-d4. This indeed follows from our account of true opinion in 2.1.

[5] A *Being Between (μεταξὺ)* the intelligible Being (τοῦ εἰλικρινῶς ὄντος) with dyad <F, notF> and the absolute not-Being (τοῦ μηδαμῇ ὄντος) is an opinable entity with respect to an intelligible Being with dyad <F, notF> 477a6-8,479d7-10.

Thus, a sensible body participating into an intelligible Being is opinable and fully known by a true opinion of that intelligible Being.[6]

2.3. The *anthyphairetic interpretation of the sensibles and of their participation in the intelligible Being*

By Sect. 2.2, the complete knowledge of a sensible body participating in an intelligible platonic Being is a true opinion of the intelligible Being, and therefore, according to the anthyphairetic interpretation of true opinion, by Sect. 2.1, it is identified with the knowledge provided by some first finite steps of the anthyphairetic division of the intelligible Being.

2.4. *The intelligible* ***is the cause of*** *every sensible body which participates in the intelligible (Phaedo 100c4-8).*

> I think that if anything is beautiful (*ἄλλο καλὸν*) besides πλὴν intelligible beauty (*αὐτὸ τὸ καλόν*), it is beautiful *for* no other reason than because it participates (*μετέχει*) in intelligible beauty *(ἐκείνου τοῦ καλοῦ)*; and this applies to everything.
> Do you assent to this view of ***cause (τῇ τοιᾷδε αἰτίᾳ)***?" "I do," said he. *Phaedon* 100c4-8

The intelligible Being is the ***cause*** of every sensible which participates in that intelligible. Thus, for a sensible body to have as ***cause*** an intelligible Being means that the knowledge of the sensible is determined by an initial finite segment of the intelligible infinite anthyphairesis.

This sense of "cause" of the sensibles will be crucial in understanding the "cause" appearing in 57d-58a in Sect. 8.

2.5. *A simplification: All sensibles participate in a unique single intelligible Being (Timaeus 30c2-31a1).*

All sensibles participate in and resemble (ἐοικὸς, ὁμοιῶσαι) a single, unique intelligible Being (the intelligible living creature, "panteles zoon")

There is a *living creature*

[1]. of which all other living creatures (τἆλλα ζῷα), severally and generically (καθ' ἐν καὶ κατὰ γένη), are parts (μόρια),
[2]. which embraces and contains within itself (ἐν ἑαυτῷ περιλαβὸν ἔχει) all the intelligible living creatures (τὰ γὰρ δὴ νοητὰ ζῷα),
[3]. which is intelligible,
[4]. which is fairest of all (*καλλίστῳ*) and in all ways most perfect (καὶ κατὰ πάντα τελέῳ) (30d1-31a1).

[6] An entity S is *opinable ("doxaston," δοξαστὸν)* with respect to an intelligible Being if the complete knowledge (γνῶναι ὡς ἔχει) of S is a true opinion of that intelligible Being. 478a6-11.

This "*unique*" intelligible being seems, somehow, at odds to what we would assume that there would be many platonic ideas. Besides, this is what we understand when reading, for example, *Phaedo* 100d where Plato says that "beautiful" things are beautiful by participating in "beauty," (ἀποκρίνασθαι ὅτι τῷ καλῷ τὰ καλὰ [γίγνεται] καλά), "great" things are great by participating in "greatness," and "smaller" things are smaller by participating in "smallness." At this point, we accept that there is a unique intelligible Being, such that all the sensible entities in the Heaven participate in and resemble to it. Thus, according to 2.1 and 2.2, every sensible can be fully described by an initial finite segment of the anthyphairesis of the unique intelligible dyad.

2.6. *The tentative identification of the unique Platonic intelligible Being in which all sensible bodies participate*

Plato, as we saw in 1.6, makes clear in the *Timaeus* 30c-31a that there is a single, unique platonic intelligible idea ("panteles zoon") into which all sensibles, all parts, and all entities in the *"kosmos"* participate. From our analysis of intelligible Beings (Sect. 1.1), we conclude that this idea, the unique intelligible Being that shapes the material world, consists of a dyad of opposites in periodic anthyphairesis.

In the *Parmenides* 130c1-2, there is talk about *intelligible fire or water* (αὐτό τι εἶδος . . . πυρὸς ἢ καὶ ὕδατος).

In the *Philebus* 29a6-d6, Plato distinguishes between sensible fire and earth and intelligible fire and earth and states that the sensible fire and earth participate in the intelligible fire and earth (οἷον πῦρ ἔστι μέν που παρ' ἡμῖν, ἔστι δ' ἐν τῷ παντί. . . τε τῆς ἐν τοῖς ζῴοις γῆς τῆς ἐνθάδε καὶ τῆς ἐν τῷ παντί).

In the *Timaeus* 51b7, he speaks of *intelligible fire* (ἆρα ἔστιν τι *πῦρ αὐτὸ ἐφ' ἑαυτοῦ* καὶ πάντα περὶῶν ἀεὶ λέγομεν οὕτως αὐτὰ καθ' αὑτὰ ὄντα ἕκαστα) in which the sensible fire participates. From the four traditional sensible bodies, Plato clearly, according to *Timaeus* 30c-31a, regards the earth and the fire as the more fundamental ones.

From the above, it is reasonable to conclude that the unique intelligible Being that shapes all "kosmos" is the dyad

$$< \text{Intelligible Earth IE}, \text{Intelligible Fire IF} >,$$

in a philosophic analogue of *periodic anthyphairesis:*

$$\begin{aligned}
&\mathrm{IE} = \mathrm{IF} + \mathrm{IE}_1, \mathrm{IE}_1 < \mathrm{IF},\\
&\mathrm{IF} = \mathrm{IE}_1 + \mathrm{IF}_1, \mathrm{IF}_1 < \mathrm{IE}_1,\\
&\mathrm{IE}_1 = \mathrm{IF}_1 + \mathrm{IE}_2, \mathrm{IE}_2 < \mathrm{IF}_1,\\
&\mathrm{IF}_1 = \mathrm{IE}_2 + \mathrm{IF}_2, \mathrm{IF}_2 < \mathrm{IE}_2,\\
&\ldots\\
&\mathrm{IE}_n = \mathrm{IF}_n + \mathrm{IE}_{n+1}, \mathrm{IE}_{n+1} < \mathrm{IF}_n,\\
&\mathrm{IF}_n = \mathrm{IE}_{n+1} + \mathrm{IF}_{n+1}, \mathrm{IF}_{n+1} < \mathrm{IE}_{n+1},\\
&\ldots
\end{aligned}$$

The sequence of anthyphairetic remainders is strictly decreasing:

$$\mathrm{IE} > \mathbf{IF} > \mathbf{IE_1} > \mathrm{I}_1 > \mathrm{IE}_2 > \mathrm{IF}_2 > \ldots > \mathrm{IE}_n > \mathbf{IF_n} > \mathbf{IE_{n+1}} > \mathrm{IF}_{n+1} > \ldots$$

(x > y means x is greater/heavier than y, y is equal to a part of x). This anthyphairetic division (of IE into IF and a smaller part IE_1 of the type IE, and so on) is formed in strict analogy to the division of the paradigmatical dyad One, Being in the second hypothesis of the *Parmenides*.

2.7. *The image account "εἰκός λόγος" of the sensibles 29c1-3*

The fact that a sensible body participates in the intelligible, as an approximate imperfect copy of the intelligible, is expressed systematically in the *Timaeus* by the expression "according to the image" ("kata to eikos," 29c). The expressions εἰκότας λόγους (29c2), κατά τό εικός (53b3) occur quite often throughout *Timaeus*, and thus it is important to have a correct rendering.

Lamb's translation of the *Timaeus* 29c1-3 is as follows:

> whereas the *accounts [λόγους]* of
> that which is *copied (τοῦ ἀπεικασθέντος) after the likeness* of that Model,
> and is itself a *likeness (εἰκόνος),*
> will be *analogous (ἀνὰ λόγου)* thereto and *possess likelihood (εἰκότας)*;
> for as Being is to Becoming, so is Truth to Belief.

As far as we can tell, this rendering of "eikos logos" has originated with Cornford 1937, and is probably based on the following misunderstanding:

> In Plato's sense of the word, we cannot have knowledge of the physical world. Plato's use of the word 'knowledge' is very strong, however, and there are differing degrees of opinion we can have concerning the physical world; we may even hold true opinions about it. Gregory 2008, p. xxxvi

This is a misunderstanding because *the complete knowledge* of a sensible participating in an intelligible Being is equivalent to the true opinion of the intelligible Being, something certainly accessible to humans.[7] This misunderstanding produces the one about "eikos logos":

[7] In *Meno,* the slave-boy is able to obtain *full knowledge* of the diameter to the side of a square (and not merely of some simple form of the Pythagorean theorem as is usually thought) by "*recollecting*," namely by repeating the logos, namely by applying the Logos Criterion for obtaining full knowledge of its periodical anthyphairesis (cf. Negrepontis, 2024); in the *Sophistes*, the full knowledge of the Angler and of the Sophist (Negrepontis 2012, 2018, 2019), and in the *Politicus* of the Statesman (Negrepontis 2018), is obtained by reaching and obtaining the logos of anthyphairetic periodicity. The *full knowledge* of a sensible equals a true opinion of the intelligible in which this sensible participates, and this is just a small "alogos" (not involving logos) part of the full knowledge of the intelligible.

> "The 'likely' part of this description stems from a word-play in the Greek, between *eikones* 'likenesses' and *eikos* 'likely'. One of the important metaphysical themes of *Timaeus* is that the cosmos is in some sense a copy or a likeness."; and "What the 'likely account' cannot do and could never do is produce knowledge, in the sense that Plato believes we can have knowledge of the forms." Gregory and Waterfield 2008, p. xxv:

M. F. Burnyeat 2005, has argued for a modification of Cornford's rendering, somewhat away from "likely" or "probable," but the move is still not enough.

Our rendering of "eikos logos" is precisely and simply as "image account," and of 29c1-3 as follows:

> the knowledge (accounts, λόγους) of the sensible
> is an *image (εἰκότας)* of the knowledge (accounts) of the intelligible
> in the same *(analogous, ἀνὰ λόγον)* way that
> the sensible bodies
> is the *likeness (τοῦ ἀπεικασθέντος)*, the image *(εἰκόνος)* of the intelligible (πρὸς μὲν ἐκεῖνο),
> **as** intelligible Being **to** sensible generation,
> **so** full knowledge of intelligible Being to true opinion of intelligible Being. **29c1-3**

The passage states that the sensible is an image of the intelligible, both ontologically and epistemologically, an echo of the Divided Line (*Politeia* 509b6-d1).

Section 3 ***[The Problem of Infinite Kosmoi] The participation of the sensibles in the intelligible infinite anthyphairetic division results in infinite "kosmoi" and in a sensible version of TMA, a consequence seemingly incompatible with the traditional One Kosmos with four kinds of sensible bodies.***

We identify *the principal,* in fact *the sole Problem,* that Plato faces with his pre-*Timaeus* theory of Sensibles, outlined in Sect. 2. The problem is that there is a built in, intrinsic infinity in every intelligible Being, and this infinity is manifested in the totality of the sensible bodies as a potential infinity: Given that a sensible entity is a "doxaston," fully knowable by an initial finite segment of the infinite anthyphairesis of the intelligible Being, we run into the difficulty of potentially an *infinite multitude of kosmoi* and the sensible version of the *Third Man Argument* (*Timaeus* 31a-b, 55c-d; Plutarch, *Obsolescence of the Oracles* 424C, 425A), both arising from the infinite multitude of anthyphairetic remainders in the intelligible Being. It seems almost impossible to reconcile and make compatible Plato's anthyphairetic theory with the older *traditional* theory, according to which there is just one Universe, one kosmos, consisting of four *elements*, earth, fire, air, and water, having no participation whatsoever in Plato's intelligible Being.

Cornford 1937 (p. 42) and other scholars do not realize that Plato introduces the Third Kind precisely in order to salvage the One Kosmos model.

> He is not offering a proof that there cannot be more than one world; he merely asserts that only one was made, because it seemed better that the copy should he unique, like the model.

3.1. *The problem of infinite "kosmoi" and of a sensible form of the Third Man Argument in the Timaeus 31a2-b3*

Right after Plato has completed his description of a sensible body as an approximate image of the intelligible Being, according to our interpretation, outlined in Sect. 2, fully knowable by an initial finite, but arbitrarily long, initial segment of the intelligible infinite anthyphairesis of the dyad earth, fire, in the passage *Timaeus* 31a-b, he states a question, essentially raising a problem.

Plato, seemingly mysteriously and out of context, raises the question whether there are infinitely many universes or finitely many. He hastens to answer that there must be only one Heaven ("ouranos") or Universe ("kosmos") . His justification is certainly unexpected, in that it involves some version of the Third Man Argument (TMA) , first presented in the *Parmenides* 131e8-132b2 Introduction. Vlastos (1954) and others believed that the argument is valid and destroy Plato's theory of intelligible Beings. The TMA has been analyzed in the context of the second hypothesis of the *Parmenides* in the Negrepontis TA paper, showing that the Argument poses no problem at all for the theory of ideas. Vlastos' reconstruction was based, among others, on the Non-Identity (NI) principle, which would be valid if an intelligible Being consisted of a dyad in merely infinite anthyphairesis, and not a periodic one. It is shown that the periodicity of the anthyphairesis in an intelligible Being, and the resulting equalization of parts, invalidates the NI principle.

The present passage in the *Timaeus*, clearly written years after the *Parmenides,* is in fact by its very presence a strong internal indication that Plato does not consider the TMA as an argument dangerous for his theory of ideas. However, if we transfer from the intelligible Being to the sensible bodies, then the Logos Criterion for periodicity is no more present, and a sensible body is completely known by a finite initial segment of the intelligible anthyphairesis. In such a situation, the TMA is valid for the sensibles, which are based only on the infinite intelligible anthyphairetic division. In fact, the validity of TMA is essentially just another form of the problem with infinite "kosmoi." Both are valid because of infinite anthyphairetic intelligible division.

> Are we right, then, in describing the Heaven as *one (ἕνα οὐρανὸν)*,
> or would it be more correct to speak of heavens
> as many or *infinite in multitude* (πολλοὺς καὶ *ἀπείρους*)?
> *One* it must be termed,
> if it is to be framed after its [intelligible] Pattern *(κατὰ τὸ παράδειγμα)*.
> For that which embraces περιέχον all intelligible Living Creatures could *never* be
> *second (δεύτερον)*, with *another* (μεθ' ἑτέρου) beside it;
> for if so, there must needs exist *yet another (ἕτερον) [third]* Living Creature,
> which should embrace them both,
> and *of which* they two would each be a part;
> in which case this Universe
> could no longer be rightly described as modelled on *these two (ἐκείνοιν),*
> but rather on *that third (ἀλλ' ἐκείνῳ)* Creature which contains them both.
> Wherefore, in order that this Creature might resemble the all perfect Living Creature
> in respect of its uniqueness (κατὰ τὴν μόνωσιν), for this reason its Maker made
> *neither two (οὔτε δύο) Universes* (κόσμους) *nor an infinite multitude (οὔτ' ἀπείρους),*
> but there is and will continue to be this **one** generated Heaven (οὐρανὸς),
> *unique* of its kind (μονογενὴς). *Timaeus* 31a2-b3

Plato hastens to answer in favor of one "kosmos," not of an infinite multitude of them, and denying the possibility of a sensible form of the TMA, but he does not really explain why. In fact, he returns to the question in the *Timaeus* 55c7-d2, exactly before introducing the four primary bodies, with which the problem is solved.

> Now in reasoning about all these things, a man might question
> whether he ought to affirm the existence of
> an *infinite multitude* of Universes *(ἀπείρους χρὴ κόσμους)*
> or a finite number *(ἢ πέρας)*;
> and if he questioned aright he would conclude that
> the doctrine of an *infinite multitude (*τὸ μὲν *ἀπείρους)* is that of
> a man unversed (τὸ μὲν *ἀπείρους*) in matters wherein he ought to be versed ***(ἔμπειρον)*;**
> *Timaeus* 55c7-d2

We will return later to study Plato's solution of the problem. For the time being, let us make sure we understand why the problem is not a whimsical, out of the blue question, but an essential and necessary question.

3.2. *The problem of infinite "kosmoi" understood, with the help of Plutarch's account, as an essential feature of the built-in infinity in Plato's dialectics*

Plutarch in *The Obsolescence of Oracles* provides a much more detailed and vivid description of the question on infinitely many "kosmoi" and helps make the question understandable.

> For if each of the bodies has *its own particular space (τόπον οἰκεῖον)*, as he asserts,
> *the earth* must of necessity turn toward the centre (*ἐπὶ τὸ μέσον*) from all directions and
> *the water* be above it *(ἐπ' αὐτῆς)*, settling below (ὑφιστάμενον)
> *the lighter elements* (τοῖς κουφοτέροις) because of its weight (διὰ βάρος).
> Plutarch, *The Obsolescence of Oracles* 424B10-C2

> If, therefore, there be *more worlds than one (πλείονες κόσμοι),*
> it will come to pass that
> *in many places the earth will rest above (πολλαχοῦ μὲν ἐπάνω) the fire and the air,* and
> *in many places below (πολλαχοῦ δ' ὑποκάτω)* them;
> and the air and the water likewise,
> in some places existing in positions in keeping with nature (κατὰ φύσιν) and
> in other places in positions contrary to nature (παρὰ φύσιν).
> Plutarch, *The Obsolescence of Oracles* 424C2-6
> [translation of the passages from Plutarch's The Obsolescence of Oracles, by F.C. Babbitt, 1936, with modifications by the authors].

The anthyphairetic interpretation of Plato's question on infinite "kosmoi" may now be obtained. According to our interpretation, described in Sect. 1, a platonic sensible entity is fully described by a finite, but possibly arbitrarily large, initial segment of the infinite intelligible anthyphairesis of the dyad <IE, IF>, generating a strictly decreasing sequence of anthyphairetic remainders:

$$IE > IF > IE_1 > IF_1 > IE_2 > IF_2 > \ldots > IE_n > IF_n > IE_{n+1} > IF_{n+1} > \ldots$$

Plutarch's account of infinite "kosmoi" combined with our interpretation of pre-*Timaeus* sensibles in Sect. 2.2 makes understandable the problem of infinite "kosmoi." The statement

> in many places (πολλαχοῦ μὲν) *the earth will rest above (ἐπάνω) the fire*
> Plutarch, *The Obsolescence of Oracles* 425A5-8

seems paradoxical at first, but if we apply faithfully the anthyphairetic interpretation outlined in Sects. 1 and 2, then it appears to be a natural consequence of the anthyphairetic interpretation of the intelligible and sensible entities. Indeed, in our interpretation of sensibles,

> the earth IE_1 will rest above the fire IF, since IE_1 is lighter than IF,
> the earth IE_2 will rest above the fire IF_1, since IE_2 is lighter than IF_1,
> . . .
> the earth IE_{n+1} will rest above the fire IF_n, since IE_{n+1} is lighter than IF_n,
> . . .,

is in excellent agreement with Plutarch's description of how the potentially "infinite kosmoi" are formed within Plato's dialectics.

Plato's anthyphairetic theory of intelligible and sensibles appears to indeed result in an infinite multitude of "kosmoi" and in particular to be incompatible with One World with four kinds of sensible bodies. The notion that there are infinitely many "kosmoi" is undesirable for Plato, as becomes clear from these two passages in the *Timaeus*. In fact, Plato is committed to One Kosmos, as is made clear in the passages of the *Timaeus* 31a2-b3 and 55c7-d2.

Plato's anthyphairetic model in its natural divisive formulation appears to be incompatible with the One World theory. Plutarch, in his account in *The Obsolescence of Oracles* 425E8-F2, makes abundantly clear this contradictory situation.

Section 4 *Every finite initial segment of an infinite* ***geometric*** *anthyphairesis can be represented by a double tight remainder-free inequality, as a dyad Receptacle-Content either in Dispersion or in Consolidation. Thus,* ***if the intelligible dyad was a geometrical anthyphairetic dyad, then every sensible body would be represented*** *by a double tight remainder-free inequality* ***as a Content*** *&* ***Receptacle dyad****.*

Thus Plato's theory of sensibles is in need of revision and modification. We present now the simple but basic mathematical ideas that Plato had in mind in his attempt to eliminate the problem of anthyphairetic infinity that enters in his description of the Sensibles, outlined in Sect. 3, and his Ingenious and imaginative description of this idea Content & Receptacle. The idea is to replace any initial finite system of an infinite anthyphairesis of two magnitudes a and b with a single double tight inequality not involving remainders. Before stating the general Basic Proposition, in 4.2, the simple manipulations can be best seen with some simple examples.

4.1. *Examples*

Example 1 Let us consider the first four initial steps in the infinite anthyphairesis of a diameter to the side of a square, whose sequence of successive quotients is equal to [1, 2, 2, 2,. . .].

With simple calculations, we find the following equivalent double inequalities:

1. The anthyphairetic relation $a = b + a_1$, $a_1 < b$ is equivalent to the double remainder-free inequality $b < a < 2b$. ($M_1 = 1$, $N_1 = 1$).
   Note that $a_1 = a - b$.
2. The system of the first two anthyphairetic equations
   $a = b + a_1$, $a_1 < b$; $b = 2a_1 + b_1$, $b_1 < a_1$
   is equivalent to the double remainder-free inequality $8a < 12b < 9a$ ($M_2 = 12$, $N_2 = 9$).
   [Indeed, $a = b + a_1$, $a_1 < b$; $b = 2a_1 + b_1$, $b_1 < a_1$ if and only if $2a_1 < b < 3a_1$ if and only if
   [by (1)] $2(a - b) < b < 3(a - b)$ if and only if $2a < 3b$ & $4b < 3a$ if and only if $8a < 12b$ & $12b < 9a$ if and only if $8a < 12b < 9a$, the double tight, remainder free inequality].
   Note that $b_1 = b - 2a_1 = b-2(a - b) = 3b - 2a$.
3. The system of the first three anthyphairetic equations
   $a = b + a_1$, $a_1 < b$; $b = 2a_1 + b_1$, $b_1 < a_1$; $a_1 = 2b_1 + a_2$, $a_2 < b_1$
   is equivalent to the double remainder-free inequality $49b < 35a < 50b$. ($M_3 = 49$, $N_3 = 35$).
   [Indeed, $a = b + a_1$, $a_1 < b$; $b = 2a_1 + b_1$, $b_1 < a_1$; $a_1 = 2b_1 + a_2$, $a_2 < b_1$ if and only if $2b_1 < a_1 < 3b_1$ if and only if [by (1) and (2)] $2(3b - 2a) < a-b < 3(3b - 2a)$ if and only if $7b < 5a$ & $7a < 10b$
   if and only if $49b < 35a$ &$35a < 50b$ if and only if $49b < 35a < 50b$, the double tight, remainder-free inequality].
   Note that $a_2 = a_1-2b_1 = (a - b)-2(3b - 2a) = 5a-7b$.
4. The system of the first four anthyphairetic equations
   $a = b + a_1$, $a_1 < b$; $b = 2a_1 + b_1$, $b_1 < a_1$; $a_1 = 2b_1 + a_2$, $a_2 < b_1$; $b_1 = 2a_2 + b_2$, $b_2 < a_2$
   is equivalent to the double remainder-free inequality $288a < 408b < 289a$. ($M_4 = 408$, $N_4 = 288$).
   [Indeed, $a = b + a_1$, $a_1 < b$; $b = 2a_1 + b_1$, $b_1 < a_1$; $a_1 = 2b_1 + a_2$, $a_2 < b_1$; $b_1 = 2a_2 + b_2$, $b_2 < a_2$ if and only if $2a_2 < b_1 < 3a_2$ if and only if [by (2) and (3)] $2(5a - 7b) < 3b - 2a < 3(5a - 7b)$ if and only if $12a < 17b$ &$24b < 17a$ if and only if $24.12a < 24.17b$ & $17.24b < 17.17a$ if and only if $288a < 408b < 289a$, the double tight, remainder-free inequality].

Example 2 We indicate the simple manipulations needed for the first two steps of any infinite anthyphairesis.

Here is how the first anthyphairetic relation

$$a = k_1 b + a_1, \text{with } a_1 < b,$$

containing the unwanted anthyphairetic remainder a_1, is transformed into the equivalent tight double inequality involving only multiples of a and b,

$$k_1 b < a < (k_1 + 1)b,$$

in which the anthyphairetic remainder a_1 has disappeared. Setting $M_1 = k_1$, $N_1 = 1$, we have

$$M_1 b < N_1 a < (M_1 + 1)b.$$

We next find (with some amazement) that the system of the first two anthyphairetic relations

$$a = k_1 b + a_1, \text{with } a_1 < b,$$

$$b = l_1 a_1 + b_1, \text{with } b_1 < a_1$$

is, setting $N_2 = (kl + 1)\ (l + 1)\ M_2 = (kl + 1)\ (k(l + 1) + 1)$, equivalent to the double tight remainder-free inequality

$$(N_2 - 1)a < M_2 b < N_2 a.$$

4.2. *The basic geometrical proposition expressing an initial finite segment of an infinite anthyphairesis in terms of a double tight inequality*

The Pythagoreans discovered the anthyphairesis of the diameter to the side of a square and subsequently studied the side and diameter numbers. Furthermore, Negrepontis (2018), based on the *Theaetetus* 147-8 passage describing Theodorus and Theaetetus' achievement on incommensurabilities, on an analysis of the fascinating palindromically periodic division of the statesman in the *Politicus,* and on the tools in the Theaetetean Book X of the *Elements*, has shown that Theaetetus had a proof of the following highly nontrivial Theorem (used in Sect. 7 below): "for every pair $a > b$ of lines such that a,b are incommensurable but a^2,b^2 are commensurable, the anthyphairesis of a to be is palindromically periodic." In the reconstruction of the proof, essential use has been made of *the generalized side p_n and diameter q_n numbers*, in order to prove the representation of every anthyphairetic remainder as an *apotome* line, in the sense of Book X of the *Elements.*

Thus, we can be reasonably certain that, thanks to Theaetetus, Plato had at his disposal the powerful mathematical techniques that are the direct progenitors of the "convergents" in modern continued fraction theory:

$$q_1/p_1 < q_3/p_3 < \ldots < q_{2n-1}/p_{2n-1} < \ldots < a/b$$
$$< \ldots < q_{2n}/p_{2n} < \ldots < q_4/p_4 < q_2/p_2.$$

Let us note here in passing that the transformation of a finite initial system of the anthyphairetic equations of a to b to a convergent (in the modern terminology of continuous fractions) provides a link for the transition from Theaetetus' theory of ratios of magnitudes based on equal anthyphairetic to the Eudoxian theory based on Dedekind-cuts.

Plato employs the following two tight double inequalities in terms of the numbers M_n and N_n which are closely related to the generalized side and diameter numbers:

$$\mathbf{M_{2n-1}b} < \mathbf{N_{2n-1}a} < (M_{2n-1} + 1)b,$$
$$(N_{2n} - 1)a < \mathbf{M_{2n}b} < \mathbf{N_{2n}a}.$$

Basic Proposition *(Pythagoreans, Theaetetus)*.

Let a, b, a > b, be a dyad of *incommensurable* magnitudes. Denote by

$$k_0, l_0, k_1, l_1, \ldots, k_n, l_n, \ldots$$

the (infinite) sequence of successive *quotients* of the anthyphairesis, and by

$$a > b > a_1 > b_1 > \ldots > a_n > b_n > \ldots$$

the (infinite) sequence of successive *remainders* of the anthyphairesis of a to b.

[1]. *Generalized Side and Diameter Numbers, Convergents*

Define the double sequence of the *generalized side and diameter numbers* of the anthyphairesis of a to be:

$$p_1 = 1, \qquad q_1 = k_0,$$
$$p_2 = l_0, \qquad q_2 = 1 + k_0 l_0,$$
$$\ldots$$
$$p_{2n-1} = k_{n-1}p_{2n-2} + p_{2n-3}, q_{2n-1} = k_{n-1}q_{2n-2} + q_{2n-3},$$
$$p_{2n} = l_{n-1}p_{2n-1} + p_{2n-2}, \quad q_{2n} = l_{n-1}q_{2n-1} + q_{2n-2},$$
$$\ldots$$

Then for all n = 1,2,...

$$a_n = p_{2n-1}a - q_{2n-1}b, \qquad b_n = -p_{2n}a + q_{2n}b,$$
$$(q_{n+2} - q_n)/q_{n+1} = (p_{n+2} - p_n)/p_{n+1},$$
$$\text{Anth}\,(q_{2n-1}, p_{2n-1}) = [k_0, l_0, \ldots, k_{n-1}],$$
$$\text{Anth}\,(q_{2n,}p_{2n}) = [k_0, l_0, \ldots, k_{n-1}, l_{n-1}],$$
$$p_{n+1}q_n - p_nq_{n+1} = (-1)^n, \text{and}$$
$$q_1/p_1 < q_3/p_3 < \ldots < q_{2n-1}/p_{2n-1} < \ldots < a/b$$
$$< \ldots < q_{2n}/p_{2n} < \ldots < q_4/p_4 < q_2/p_2.$$

[2]. *Representation of every finite initial segment of a geometric infinite anthyphairesis as a tight inequality of the form Receptacle & Content, alternately in Dispersion or in Consolidation*
We set

$$M_1 = q_1, \qquad N_1 = p_1,$$
$$M_{2n-1} = q_{2n-1}(p_{2n-2} + p_{2n-1}), \qquad N_{2n-1} = p_{2n-1}(p_{2n-2} + p_{2n-1}); \text{and},$$
$$M_{2n} = q_{2n}(q_{2n-1} + q_{2n}), \qquad N_{2n} = p_{2n}(q_{2n-1} + q_{2n}).$$

Then, for every natural number n,

$$\text{Anth}\,(M_{2n-1}, N_{2n-1}) = \text{Anth}\,(q_{2n-1}, p_{2n-1}) = [k_0, l_0, \ldots, k_{n-1}],$$
$$\text{Anth}\,(M_{2n}, N_{2n}) = \text{Anth}\,(q_{2n,}p_{2n}) = [k_0, l_0, \ldots, k_{n-1}, l_{n-1}],$$
$$M_1/N_1 < M_3/N_3 < \ldots < M_{2n-1}/N_{2n-1} < \ldots < a/b < \ldots < M_{2n}/N_{2n}$$
$$< \ldots < M_4/N_4 < M_2/N_2; \text{ and}$$

(i) The system of the first 2n + 1 anthyphairetic equations a and b

$$a = k_0b + a_1, b = l_0a_1 + b_1, \ldots, a_{n-1} = k_{n-1}b_{n-1} + a_n,$$

is *equivalent* to the double inequality of *Dispersion (diakrisis)*

$$\mathbf{M_{2n-1}b} < \mathbf{N_{2n-1}a} < (M_{2n-1} + 1)\ b; \text{ and},$$

(ii) The system of the first 2n steps of the anthyphairesis a and b

$$a = k_0b + a_1, b = l_0a_1 + b_1, \ldots, a_{n-1} = k_{n-1}b_{n-1} + a_n, b_{n-1} = l_{n-1}a_n + b_n,$$

is *equivalent* to the double inequality of *consolidation (sugkrisis)* even order-*n*

$$(N_{2n} - 1)a < \mathbf{M_{2n}b} < \mathbf{N_{2n}a}.$$

The (elementary) *proof* of the basic Proposition will not be reconstructed here.

4.3. *Plausible interpretations and heuristics*

The problem of "infinite kosmoi" is the infinity of anthyphairetic remainders, and Plato intends to "cure" it, in Plutarch's words. But Plato is obliged because of a serious problem at 48ff to introduce the mysterious Third Kind/Receptacle. Our informal reasoning suggests that Plato's introduction of the Receptacle is somehow related to his intention to "cure" the infinite kosmoi/infinite anthyphairetic remainders problem.

The infinity of anthyphairetic remainders of a geometric anthyphairesis can be "cured" by reverting to the equivalent tight remainder-free double inequalities, closely related to generalized side and diameter numbers-modern convergents. So our plausible reasoning is guiding us to the conclusion that Plato's "cure" is by means of such tight double inequalities.

Now our heuristic reasoning suggests that the concepts introduced by Plato to deal with the problem, such as

> Receptacle & Content,
> filled quite fully so that not even one more can be added,
> defeated and victorious part,
> becoming dissimilar to itself and similar to others,
> dispersion or consolidation,

actually fit surprisingly well as interpretations of the mathematical inequalities. But before proceeding with our informal, plausible heuristics, we want to consider the sense of Receptacle in Aristotle and in Plato, through Aristotle's critique.

The initial idea, in early form, that the basic geometric Proposition 4.2 is at the basis of the Receptacle in the *Timaeus*, appeared in Negrepontis 2005, (F).

4.4. *The clarification of Plato's concept of receptacle/place-content by Aristotle's criticism*

Aristotle sets six conditions (which we numbered [1] to [6]) for something to be *immediate place* (τόπος) or container of a sensible entity.

But what actually is *place* (*τόπος*)? Here is a way to find an answer. Let us take as premisses all the properties which seem genuinely to belong to *place* in its own right. This is what we expect to be true of *place* (*τόπον*)[8]:

[8] The Third Kind is described as "chora" (τρίτον δὲ αὖ γένος ὃν τὸ τῆς χώρας, 52a8; ὄν τε καὶ χώραν καὶ γένεσιν εἶναι, 52d3; σφίγγει πάντα καὶ κενὴν χώραν οὐδεμίαν ἐᾷ λείπεσθαι. 58a7). Thus "chora" is identical with the Receptacle, the place in which the generation of the sensibles takes place. In 52b4-5, the sentence "τὸ ὂν ἅπαν ἔν τινι τόπῳ καὶ κατέχον χώραν τινά" makes clear that "topos" is still another term for the Receptacle.

Aristotle in *Physics* 209b11-16 clearly identifies platonic "chora" and "topos," with the Receptacle.

[1] that it is the immediate container (πρῶτον . . .περιέχον) of
that of which it is the place *(τόπος)*,
[2] that it is not a part of the object it contains,
[3] that a thing's *immediate place (πρῶτον [τόπον])* is exactly the same size as it,
[4] that it can be left behind (ἀπολείπεσθαι) by the object and is separable (χωριστὸν)
from it,
[5] and also that every *place (τόπου)* admits of the distinction between above and below,
[6] and that every body naturally moves up or down to its own *proper place (οἰκείοις τόποις)*
and stays (μένειν) there. *Physics* 210b32-211a5
[translation of Aristotle's Physics passages in the paper by Bostock, Waterfield, 1996, with modifications by the authors]

By [1] and [3], the place must contain the content and nothing else. They are made explicit also in 209a32-b1.

Place (τόπος) may refer
either to the shared (κοινός) place which contains all bodies
or to the particular (ἴδιος) place which *immediately contains (ἐν ᾧ πρώτῳ)* a body.
For instance, you are now in the world, because you are in the air and the air is in the world;
and you are in the air because you are in the earth;
and by the same token you are in the earth because
[3] you are in this *particular place (ἐν τῷδε τῷ τόπῳ)*,
which contains nothing more than you (ὃς περιέχει οὐδὲν πλέον ἢ σέ). 209a32-b1

By [2] and [4], the place is not a part of the contained, and so it can be left behind; in this, Aristotelian "*topos*" differs from the Platonic. This is also made explicit in 209b28-33:

In fact, people do think of *place (τόπος)* as being like a vessel *(τὸ ἀγγεῖον)*
(since a vessel is a *movable place (τόπος μεταφορητός)* and
[2, 4] a vessel is not a part of the object οὐδὲν τοῦ πράγματός it contains.

The following passage is a critique of Plato's sense of place in the *Timaeus*, where the Receptacle/place is an inseparable part of the sensible entity.

however true it may be that one is in the other,
the jar *(ἀμφορεὺς)* will still *contain (δέξεται)* the wine (οἶνον)
not because it is itself wine (αὐτὸς οἶνος), but because it is *a jar (ἐκεῖνος),* and
the *wine (ο νος)* will be in (ἐνέσται) *the jar (ἐν τῷ ἀμφορεῖ)*
not because it is itself a jar, but because it is wine. *Physics* 210b13-17

Conditions [5] and [6] about "proper places" find Plato in agreement.

Thus, for both Plato and Aristotle the basic property of the Receptacle is that it contains the Content and nothing more, or, more precisely, *not even one part more*. (We will indicate the difference of the two both in 4.5 below, but especially in Sect. 9, [3].)

A main feature and peculiarity of Plato's Receptacle/Place turns out to be that surprisingly it is *not separate* from the Content, the "matter" (hule), but an integral

part of it, while on the contrary Aristotle considers, as we would find reasonable, that the containing Receptacle is separate from the thing it contains, and criticizes the platonic sense of Chora.

4.5. *More heuristics*

We wish next to obtain a plausible interpretation of the tight double inequalities obtained in 4.2 as a dyad Receptacle & Content.

We claim that in trying to make more vivid and colorful, but still faithful to the mathematics involved, the nonmathematical language, Plato introduces the term *Receptacle* (*ὑποδοχὴ*) or *place* (*τόπος, χώρα*).

The Receptacle or Place of an object is the immediate Container of another object, the Content. Recall that according to Aristotle's *Physics* 210b-211a, as we saw in 4.4, the Receptacle contains the object, its Content, it is filled by it, and it can contain nothing more, not even one thing more (for the exact uses of this last statement by Plato, we will have to wait till Sect. 9).

In both of these types of tight double inequalities

$$[1]\ \mathrm{Mb} < \mathrm{Na} < (\mathrm{M}+1)\mathrm{b},\ [2]\ (\mathrm{N}-1)\mathrm{a} < \mathrm{Mb} < \mathrm{Na},$$

the inequality **Mb < Na** holds, which may be interpreted as saying that the mass Mb of the small b, the Content, enters the mass Na of the great a, the Receptacle/Place; both of these inequalities and entrances are tight in the sense that the Content *completely fills* the Receptacle, but in different senses:

In [1] in the sense that attempting *to add even one* b makes the mass (M + 1)b go above Na, namely in the sense that the *Content is maximal*, while
In [2] in the sense that attempting *to subtract even one* a makes the mass (N − 1)a go below Mb, thus in the sense that the *Receptacle is minimal*

It follows that

In [1], b is the active/victorious part and a is the passive/defeated part; the mass Na of great parts becomes similar to, takes the shape of its opposite mass Mb of small parts, and can thus be described as *Dispersion (διάκρισις)*; while
In [2], the mass Mb of small parts becomes similar to, takes the shape of its opposite mass Na of great parts, and can thus be described as *consolidation (σύγκρισις)*.

It is then an excellent terminology to think of the mass Na as the *Receptacle* and the mass Mb as its *Content.*

We will gradually in the sequel support our heuristics with strong evidence, culminating in Sects. 8 and 9.

Section 5 ***But unfortunately, the elimination of anthyphairetic remainders and their replacement with tight double inequalities make no sense for the intelligible dyad, hence the representation of a sensible body as Content & Receptacle of the intelligible dyad is impossible.***

The reader might have noticed that the idea we mentioned in Sect. 4 was strictly for an infinite anthyphairesis of magnitudes, of *geometric* entities, and we were careful not to mention its philosophic analogue, the intelligible Being, and the platonic idea. Were it possible to assume that the transformation, by means of mathematical manipulations, of an initial finite system of relations of an anthyphairesis of a geometrical dyad works equally well and produces corresponding philosophical *intelligible* Receptacle & Content pairs, we would be able to obtain a theory that combines one kosmos and four sensible bodies (in a modification of the traditional theory of four elements) with participation of the sensibles in the intelligible Being <IE, IF>.

But, this is definitely NOT the case! We can see this clearly and directly as follows. The mathematical manipulations, involving the generalized side and diameter numbers, equivalently the modern convergents, leading to the tight double remainder-free inequalities and the Receptacle & Content representation are valid if a and b are geometric magnitudes, but they definitely make no sense at the philosophical, intelligible level. Thus, for example, the first intelligible anthyphairetic relation

$$\mathrm{IE} = \mathrm{IF} + \mathrm{IE}_1, \text{with } \mathrm{IE}_1 < \mathrm{IF},$$

cannot possibly be translated to the double inequality

$$\mathrm{IF} < \mathrm{IE} < 2.\mathrm{IF}.$$

Plato states clearly this problem with his two passages (*Timaeus* 51e6-52a4, 52c5-d1), according to which a mass of the intelligible fire, the small, cannot enter into a mass of the intelligible earth, the great.

Thus Plato's idea to eliminate the infinity of anthyphairetic remainders works for a geometric pair in infinite anthyphairesis but fails for its philosophic analogue, the intelligible dyad <IE, IF>.

5.1. Plato states clearly this problem with his two passages (*Timaeus* 51e6-52a4, 52c5-d1), according to which the intelligible dyad <IE, IF> does not satisfy the Receptacle-Content inequalities

> This being so, we must agree that one is
> the self-identical Kind (τὸ κατὰ ταὐτὰ εἶδος) [=the intelligible true Being],
> ungenerated and indestructible,
> *neither receiving* into itself any other from elsewhere
> (οὔτε *εἰς ἑαυτὸ εἰσδεχόμενον* ἄλλο ἄλλοθεν)
> *nor* itself *entering* anywhither into another
> (οὔτε αὐτὸ εἰς ἄλλο ποι *ἰόν*),
> invisible and in all ways imperceptible by sense,
> it being the object which it is the intelligence *(νόησις)* to contemplate 51e6-52a4

Thus, according to 51e6-52a4, the dyad of the intelligible Being, whether it is the dyad < One, Being > of the second hypothesis of the *Parmenides*, or the dyad <IE, IF>, cannot possibly generate a sensible by having a mass of the smaller part, acting as Content, enter a mass of the greater part, acting as Receptacle.

> whereas to the aid of the true Being (τῷ δὲ ὄντως ὄντι) [=the intelligible true Being]
> there comes the *accurately true Logos* (ὁ δι' ἀκριβείας ἀληθὴς λόγος),
> that so long as (ὡς ἕως ἄν)
> one thing is one thing, and another something different (τὸ μὲν ἄλλοῇ, τὸ δὲ ἄλλο),
> it will *never (ποτὲ) happen* that
> one thing will be *generated in the other thing* (οὐδέτερον *ἐν οὐδετέρῳ γενόμενον*)
> so that they *become* (γενήσεσθον) the same thing *(ταὐτὸν)*
> simultaneously *(ἅμα)* both one and two *(ἓν καὶ δύο).* 52c5-d1
> [[translation by Lamb, with modification by the authors]]

As explained in 5.1 this is so because for the *intelligible* dyad a,b, a mass Na or Mb makes no sense, and hence the entrance of the mass Mb of small b's into the mass Na of great a's makes even less sense.

5.2. The Content & Receptacle transformation of geometric anthyphairesis, described in Sect. 4, is quite attractive, and Plato would be happy to adopt it for his theory of the sensibles, in order to overcome the difficulty with infinite kosmoi and sensible TMA. But unfortunately, a platonic true Being is a *philosophical analogue* of a geometric periodic anthyphairesis between two magnitudes, and not a bona fide geometric one, and this presents a serious problem.

The arithmetical sequence of approximating generalized side and diameter numbers' tight inequalities we derived in Sect. 4,

$$\begin{aligned} \mathbf{M_{2n-1}b} \quad &< \mathbf{N_{2n-1}a} < (\mathrm{M}_{2n-1} + 1)\,\mathrm{b} \;\; (\textit{Dispersion}), \text{and,} \\ (\mathrm{N}_{2n} - 1)\mathrm{a} \quad &< \mathbf{M_{2n}b} < \mathbf{N_{2n}a} \;\; (\textit{Consolidation}), \end{aligned}$$

starting with a finite initial segment of the infinite anthyphairesis of a to b, were the result of perfectly allowable mathematical manipulations. These mathematical manipulations are valid, if a and b are magnitudes, but definitely make NO sense, if a and b are the parts of an indefinite philosophical dyad, such as the dyad <One, Being> in the *Parmenides*, the dyad <Being, Not-Being> in the *Sophistes*, and the intelligible dyad <IE, IF>. As already indicated above, it makes no sense to attempt to transform the intelligible anthyphairetic relation $\mathrm{IE} = \mathrm{IF} + \mathrm{IE}_1$, with $\mathrm{IE}_1 < \mathrm{IF}$, into the double remainder-free inequality IF <IE <2.IF of the form Content & Receptacle; more generally since M.IF, N.IE make no sense, the Content & Receptacle inequalities also make no sense, and thus we cannot get rid of the infinitely many intelligible remainders in the same way that we can get rid of the geometrical remainders.

Section 6 ***The geometric dyad of Triangle A and Triangle B (53c4-d7, 54a1-d7), and the generation of the surfaces of the four canonical solids, of cube from Triangle A, and of pyramid, 8hedron, and 20hedron from Triangle B (54d5-55c6)***

We describe the introduction of

Triangle A, the isosceles right angle triangle which is, half of the square, from which the *surface* of the cube/6hedron is generated, and
Triangle B, the orthogonal triangle having the ratio 2/1 of the hypotenuse to one side, half of the equilateral triangle, from which the **surface** of the pyramid/4hedron, 8hedron, and 20hedron are generated.

6.1. *The dyad Triangle A and Triangle B is introduced as the principle of the four primary bodies (Timaeus 53c4-d7, 54a1-d7).*

The two *principles* of the four primary bodies, triangles A and B, are obtained by a sequence of five reductions:

> –*First of all* (Πρῶτον μὲν), it is obvious to everyone (δῆλόν που καὶ παντί), that
> *fire, earth, water, and air* (πῦρ καὶ γῆ καὶ ὕδωρ καὶ ἀὴρ) are
> –*bodies* (ὅτι σώματά ἐστι); and all body (τὸ δὲ τοῦ σώματος εἶδος πᾶν) has
> – *depth* (βάθος). Depth (βάθος), moreover, must be (αὖ πᾶσα ἀνάγκη) bounded by
> – *surface* (ἐπίπεδον περιειληφέναι),

[here Plato limits consideration to rectilinear surfaces only, excluding the circle, cf. definition I.19 of Euclid's *Elements*]

> and any *surface* bounded by straight lines (ὀρθὴ τῆς ἐπιπέδου βάσεως) is composed of
> – *triangles* (τριγώνων). Now all *triangles* derive their origin from *two triangles*, each having one angle right and the others acute; and the one of these triangles has on each side half
> **a** *right angle* marked off by equal sides, while the other has the *right angle* divided into unequal parts by unequal sides.

[here Plato prepares the way to further limit consideration to the surfaces of the four of the five canonical solids, studied by Theaetetus in Book XIII of Euclid's *Elements*]

> These we lay down as *the principles (ἀρχὴν)* of *fire and all the other bodies*, proceeding according to a method in which the probable is combined with the necessary;
> –but *the principles (ἀρχὰς) which are still higher* than these
> are known only to God and the man who is dear to God. 53c4-d7

Definition
Triangle A is the isosceles right triangle (54a1-2).
Among the infinitely many scalene right triangles, Plato, guided by criteria and considerations of *beauty and fairness* (54a2-b1), determines that

Triangle B is the right triangle that generates the equilateral triangle, namely the one which has its hypotenuse twice as long as its lesser side (54a5-b1, 54b4-5, 54d5-7).

> Now of the two triangles, *the isosceles* possesses one single nature, 54a1-2
> but *the scalene (πρόμηκες)* an infinite number;
> and of these infinite natures we must select *the fairest (τὸ κάλλιστον),*
> if we mean to make a *suitable principle* (εἰ μέλλομεν *ἄρξεσθαι κατὰ τρόπον*).
> If, then, anyone can claim that he has chosen one that is *fairer (κάλλιον)* for the construction
> of these bodies, he, as friend rather than foe, is the victor. 54a2-5
> We, however, shall pass over all the rest
> and postulate as *the fairest (κάλλιστον)* of the triangles
> *that triangle* out of which, when two are conjoined,
> the *equilateral (ἰσόπλευρον) triangle* is constructed as a third. 54a5-b1
> and the other [triangle] that which always has the square on its greater side (τὴν μείζω πλευρὰν) *three times* the square (τριπλῆν κατὰ δύναμιν ἔχον) on the lesser side (τῆς ἐλάττονος) 54b4-5
> that triangle which has its hypotenuse (τὸ τὴν ὑποτείνουσαν)
> *twice as long* (διπλασίαν ἔχον μήκει) as its lesser side (τῆς ἐλάττονος πλευρᾶς) 54d5-7

The dyad of triangles A and B is a dyad of opposites, since Triangle A is characterized by *Equality* while Triangle B by *inequality* of their perpendicular sides. Together they form *the most beautiful* geometric dyad. Both features are basic; we will be able to explain in the sequel their significance (Sect. 8.4 for inequality, Sect. 10 for beauty).

6.2. Proposition *Triangles A and B are the* ***principles and elements*** *of (the surfaces of) four of the five canonical solids:*

The (surface of the) canonical 6hedron/cube is equal to 24A.
The (surface of the) canonical 4hedron/pyramid is equal to 24B.
The (surface of the) canonical 8hedron is equal to 48B.
The (surface of the) canonical 20hedron is equal to 120B (54d5-55c6).

Once the triangles A and B have been introduced and defined, Plato proceeds to generate from them, considered as principles and elements, the surface of the four of the canonical polyhedra. The four, of the five (the 12hedron is mentioned at 55c4-6), canonical polyhedra are constructed and *comprehended in a sphere*, the 4hedron/pyramid (in Proposition XIII.13 of the *Elements*), the 8hedron (in XIII.14), the 20hedron (in XIII.16), and the 6hedron/cube (in XIII.15). The comprehension of the canonical polyhedra in a sphere comes up in passage 58a4-7, analyzed in Sect. 10.

The surface of a pyramid consists of four equilateral triangles. An equilateral triangle is divided into two triangles of the form Triangle B; thus, the surface of a pyramid consists of 8 triangles B. But in fact, Plato divides the equilateral triangle into six rather than two triangles B, by dividing the equilateral triangle by means of the three heights. Thus, Plato divides the surface of the pyramid into 24 triangles B. By dividing

- The surface of the pyramid into 24 triangles B, rather than 8 triangles B, and
- The surface of the cube into 24 triangles A, rather than 12 triangles A,

Plato succeeds in dividing the pyramid and the cube into an *equal* number of their corresponding elements, with the result that the relation of the two fundamental regular solids (cube and pyramid) is precisely the same as the relation of their respective elements (Triangle A and Triangle B).

It certainly comes as a surprise that Plato treats throughout *Timaeus* the four canonical solids, **not** as solids with volume, but considering *ONLY their surfaces.* The reason will become evident in the next section.

Section 7 *The incommensurability, in fact periodicity of the anthyphairesis, of Triangle A to Triangle B (54b5-d3, 56d1-6)*

Plato insists on the exchangeable nature of the surfaces of the three canonical solids (4hedron, 8hedron, 20hedron), according to the arithmetical ratio 4:8:20 = 1:2:5, because they have a common unit, measure Triangle B, and are thus *commensurable* to each other,

but declares impossible the exchangeability presumably according to an arithmetical ratio, with the cube, because of the impossibility to exchange a mass of Triangle A with a mass of Triangle B (54b5-d3, 56d1-6). Such impossibility can only mean that the areas of the triangles A and B do not have a common measure, namely that they are *incommensurable*.

Note that these triangles are defined only up to their similarity equivalence class. Plato says nothing about the absolute size of these two triangles, and we might easily arrange so that some size of Triangle A is even equal to some other size of Triangle B. But how can it be established that Triangle A is *incommensurable* to Triangle B?

We now describe how we are able to establish the *incommensurability* of Triangle A to Triangle B, and *a fortiori* the incommensurability of the surface of the cube to the surface of each of the canonical solids pyramid, 8hedron, 20hedron. We were indeed able to discover the *canonical comparison* of the two triangles:

We consider Triangle A as the half of the square face of the cube.
Triangle B as the half of the equilateral triangle face of the pyramid.
We *comprehend* the pyramid and the cube *in the same sphere*, as Theaetetus does in Propositions (13, 15 &) 18 of Book XIII of the *Elements*; it can then be proved that the hypotenuse of Triangle A and of Triangle B are equal.

The canonical comparison of Triangle A and Triangle B and the resulting equalization of the hypotenuses of the two triangles reveal that the (linearized) ratio of the areas of the two triangles is indeed incommensurable, but nevertheless *commensurable in square*. The study of these *quadratic incommensurabilities* was started by the Pythagoreans, continued later by Theodorus, and culminated again by Theaetetus, as reported by Plato in the dialogues *Theaetetus*, *Sophistes*, and *Politicus*. As shown in Negrepontis 2018, Theaetetus developed the necessary

tools in Book X of the *Elements* and established the highly nontrivial theorem that the anthyphairesis of every quadratic incommensurability (namely, an incommensurability of lines, whose squares are commensurable) is *palindromically periodic*, a theorem imitated by Plato to define, by division and collection, the statesman in his dialogue *Politicus*.

Proposition The geometric dyads <Triangle A, Triangle B> and <surface of cube = 24A, surface of 20hedron = 120B> are incommensurable, and in fact in periodic anthyphairesis.

There are two crucial advantages gained by treating these canonical solids as surfaces:

The first is the incommensurability, and in fact the *anthyphairetic periodicity*, of the dyad <cube, 20hedron>, a fact whose importance will be seen in the generation of the sensible bodies (Sects. 8 and 9); and

The second is the mutual *commensurability* of the three solids 4hedron, 8hedron, and 20hedron, a fact that will allow Plato to subsume the traditional four body theory in modified form in his account of the sensibles (Sects. 8 and 9).

7.1. *The impossibility of exchanging a mass of triangles A with a mass of triangles B, (54b5-d3), or a mass of primary earth with a mass of primary water, or air, or fire, (56d1-6), can only mean the incommensurability of Triangle A to Triangle B.*

> Moreover, a point about which our previous statement was obscure must now be defined more clearly. It appeared as if the four Kinds *(τὰ τέτταρα γένη)*, in being generated (γένεσιν ἔχειν), all passed through one another into one another, but *this appearance was deceptive*.
> For out of the triangles [triangles A and B] which we have selected
> four Kinds are generated,
> *three of them* [4hedron, 8hedron, 20hedron] out of that one triangle which has its sides unequal [triangle B], and
> *the fourth Kind* [6hedron] *alone* composed of the isosceles triangle [triangle A].
> Consequently, *they are not all capable* of being dissolved into one another so as to form a few large bodies composed of many small ones, or the converse;
> *but three of them* do admit of this process (**τὰ δὲ τρία οἷόν τε**). For these three are all (ἅπαντα) naturally compounded of one triangle [[triangle B]], so that when the larger bodies ***(τῶν μειζόνων)*** are dissolved (λυθέντων) many small ones will form themselves from these same bodies (*πολλὰ σμικρὰ ἐκ τῶν αὐτῶν συστήσεται*), receiving (δεχόμενα) the shapes that befit them (τὰ προσήκοντα ἑαυτοῖς σχήματα); and conversely, when many small bodies (σμικρὰ ὅταν αὖ πολλὰ) are resolved (διασπαρῇ) into their triangles *(κατὰ τὰ τρίγωνα),* they will produce (ἀποτελέσειεν ἄν), when unified, one single large mass of another Kind (ἕκαστον αὐτῶν γέγονεν εἶδος). So let thus much be declared concerning their generation into one another. 54 b5-d3

The same exchangeability between the three canonical bodies and the same impossibility of exchange between each of the three and the fourth are described in physical terms for the four primary bodies (to be defined in Sect. 8 in terms of the

surfaces of the four canonical solids). In geometrical language, the rule of intergeneration of the three regular solids lies on the simple fact that their surfaces have as common unit Triangle B. Thus

4hedron = 24 Triangle B, 8hedron = 48 Triangle B, and 20hedron = 120 Triangle B.

Therefore,

2. 4hedron = 1. 8hedron, 5. 4hedron = 1.20hedron, and 1.20hedron = 2. 8hedron + 1. 4hedron.

> Given all we have said so far about *the kinds (τὰ γένη)*, the following account
> [of their generation to each other] is according to the image account (κατὰ τὸ εἰκὸς):
> When [primary] *earth* encountering [primary] fire and being *dissolved (διαλυθεῖσά)*
> by [primary] fire's sharpness is set in motion, being *dissolved (λυθεῖσα)*
> either within [primary] fire itself, or within a mass of [primary] air or [primary] water,
> until (μέχριπερ) its parts, encountering themselves somewhere, being refitted together (συναρμοσθέντα) again, become (γένοιτο) [primary] *earth*.
> The reason is that
> *the parts of [primary] earth will never pass into another [primary] kind (ε δος)* 56d1-6

Plato emphasizes that the "*earth will never pass into another kind.*" Since the generation "according to the triangles" (54c4) that works for the other three solids is rejected for the earth, we understand clearly that the impossibility of exchange of solid earth with the other three solid kinds is due to the impossibility of exchange of their surfaces. In effect, these exchanges are impossible, because

the exchange of Triangle A with Triangle B is impossible.

Plato states that the earth will never turn into any of the other three solids, meaning that such turning into is impossible in the sense of the generation according to the triangles, namely by *equating* the surface areas of the corresponding masses of earth and say water. This can be expressed as follows:

The surface area of a mass of earth/cubes will never be *equal* to the surface area of a mass of fire/pyramids. Since the surface area of a mass of earth/cubes is equal to M.A for some number M, and the surface area of a mass of fire/pyramids is equal to N.B for some number N, it follows that

there are no natural numbers M and N such that
the two areas M.A and N.B are equal, M.A = N.B.

Mathematically, this is expressed in terms of the concept of *commensurability* that appears in the Theaetetean Book X of the *Elements*:

Definition X.1 of Euclid's *Elements*.

Those magnitudes are said to be *commensurable (σύμμετρα μεγέθη)*
which are measured by the same measure (τὰ τῷ αὐτῷ μέτρῳ μετρούμενα), and those *incommensurable (ἀσύμμετρα)*
which cannot have any common measure (μηδὲν ἐνδέχεται κοινὸν μέτρον).

Thus Plato's statement that primary earth cannot be transformed to one of the other three primary bodies according to the triangles is equivalent to the statement that

(the area of) Triangle A is *incommensurable* to (the area of) Triangle B.

But how can it be established that Triangle A is *incommensurable* to Triangle B? Plato provides no information about the absolute size of these two triangles, and we might easily arrange so that some size of Triangle A is even equal to some other size of Triangle B. Thus Plato's claim of incommensurability must rely on a *canonical* way of comparing Triangle A to Triangle B.

7.2. *The **canonical comparison** of the triangles A and B is achieved by inscribing pyramid and cube **in the same sphere**, as in Propositions XIII. Total (13, 15 &) 18 of the Elements, by equating their hypotenuses, and the resulting **periodicity of the anthyphairesis of Triangle A to Triangle B**.*

Plato does not explain how these two elementary triangles are to be compared so that they are incommensurable, but since he clearly implies that they are incommensurable, he must have some specific "*canonical*" comparison in mind. In order to discover this canonical comparison, we must take into consideration that Plato is following the mathematical description of the canonical polyhedra, as presented in the Theaetetean Book XIII of the *Elements*.

Below we present that the canonical comparison of the areas of the triangles A and B is achieved (when the regular solids are comprehended in the same sphere) by equating *their hypotenuses.* We want to compare the hypotenuses of the two triangles, the hypotenuse p of the Triangle A is the *diameter* of the sphere comprehending the square of a cube, satisfies $p^2 = 2\,k^2$ (k the side of the square), and the hypotenuse q of the Triangle B is the side of the equilateral triangle of a pyramid. We recall that Plato calls "diameter" the hypotenuse of the triangle and builds the solids as inscribed in a sphere (55a3).

*Pyramid and cube constructed and comprehended in the **same** sphere:*

In Book XIII, these computations are first performed for each canonical solid separately, in Proposition XIII.13 for the pyramid and in Proposition XIII.15 for the cube, and then in Proposition XIII.18 all canonical polyhedra are comprehended and compared in *the same* sphere. These Propositions suggest the way for the canonical comparison of the areas of the triangles A and B. Triangle A will be compared to

Triangle B, when
Triangle A is considered as a constituent part of the surface of a cube.
Triangle B is considered as a constituent part of the surface of a pyramid.
AND these two solids, the cube and the pyramid, **are** *comprehended in the same sphere* (σφαίρᾳ περιλαβεῖν), as in fact in *Propositions XIII.13, 15, 18.* We obtain the following

Proposition
If a pyramid and a cube are comprehended *in the same sphere,* then the side of the triangle face of the pyramid, namely *the hypotenuse of triangle B is equal to* the diameter of the square face of the cube, namely *the hypotenuse of triangle A*.

Proof
Indeed, in the common sphere of diameter D,
the side q of the pyramid satisfies $q^2 = (2/3)D^2$
(by Proposition XIII.13 of the *Elements*), and
the side k of the cube satisfies $k^2 = (1/3)D^2$
(by Proposition XIII.15 of the *Elements*).

This allows for the *canonical comparison* of Triangle A and Triangle B: The hypotenuse of the Triangle B is the side q, and the hypotenuse p of the Triangle A satisfies (by the Pythagorean theorem I.47 of the *Elements*) $p^2 = 2\ k^2$.
Thus, we have $q^2 = (2/3)D^2 = 2\ (1/3)D^2 = 2\ k^2 = p^2$. Hence q = p.
Thus, we are led to compare the areas of triangles A and B *by identifying their hypotenuses.*

7.3. Proposition *Under the* ***canonical comparison*** *Triangle A and Triangle B are incommensurable. In fact, the anthyphairesis of any mass N.A to any mass M.B (where M and N are natural numbers) is periodic, hence infinite, hence the dyad NA, MB is incommensurable.*

This crucial property of the triangles A and B, and of the surfaces of any mass of primary earth/cube to the surfaces of any mass of, say, primary water, explains fully why Plato resorted to the *surfaces* of the regular solids, *not* considering at all *their volumes:* The reason lies exclusively with the remarkable fact that these surfaces are related to *periodic anthyphairesis*, and thus connect closely with *intelligible Being*.

Proposition

(i) (area of) triangle A > (area of) triangle B,
(ii) the area of triangle A is *incommensurable* to the area of triangle B,
(iii) if r and s are line segments with r:s = area of triangle A: area of triangle B, then the ratio $r^2:s^2$ is commensurable, and
the anthyphairesis of (area of) triangle A to (area of) triangle B is infinite, in fact periodic.

(iv) [Theaetetus][9] the *anthyphairesis* of (area of) any mass NA of triangles A (where N is any natural number) to (area of) any mass MB of triangles B (where M is any natural number), with MB < NA, is infinite, in fact *periodic.*
(v) The anthyphairesis of the surface of the cube to the surface of the 20hedron is periodic.

Proof
Ad (i). Triangle A and Triangle B have a common diameter, say D, as seen in the previous Proposition. Since Triangle A is isosceles and Triangle B scalene, it is clear that area of Triangle A > area of Triangle B.
Ad (ii). Setting x for side of Triangle A,
we have that the area of Triangle A is $x^2/2$; since $2x^2 = D^2$,
the area of the Triangle A is equal to $D^2/4$; and,
setting y,z for the sides of Triangle B,
we have the area of Triangle B is yz/2, and since $z^2 = 3y^2$ and $4y^2 = D^2$, it follows that $2y = D$, $y = D/2$, and $z^2 = 3y^2 = 3/4\ D^2$,
hence (in modern notation) $z = \sqrt{3}/2\ D$; thus,
the area of the Triangle B is equal to $\sqrt{3}/8\ D^2$.
Hence (area of) Triangle A: (area of) Triangle B = $2{:}\sqrt{3}$.
Thus, the ratio area of Triangle A: Area of Triangle b is incommensurable (by Theodorus' theorem); by Proposition X.2 of the *Elements*, the anthyphairesis of Triangle A to Triangle B is infinite.
Ad (iii). If r and s are line segments, such that $r{:}s = 2{:}\sqrt{3}$, then $r^2{:}s^2 = 4{:}3$, commensurable.
By Theaetetus' theorem, this anthyphairesis is (eventually) periodic.
Ad (iv). By Theaetetus' theorem.
Ad (v). Special case of (iv).

The incommensurability of the surface of the cube to the surface of the 20hedron is fundamental and absolutely necessary for the introduction of the Third Kind, defined and examined in Sects. 8 and 9, by means of which the infinite kosmoi are avoided.

[9] Theaetetus' Theorem states: If a and b are line segments, such that a > b, a,b incommensurable, and a^2, b^2 commensurable, then the anthyphairesis of a to b is palindromically periodic. In Negrepontis 2018, it is shown (a) how the study of the *Politicus* dialogue leads to the inescapable conclusion that Plato had perfect knowledge of this Theorem, and (b) how the Theaetetean Book X of the *Elements* contains all the tools necessary for the proof of this Theorem, namely the notion of the *apotome* line and of the line *of two names*, and principally Propositions X.112–114. A complete proof of the palindromic periodicity theorem using only the tools of Book X of the *Elements* is given in Negrepontis (Notes by V. Kleftaki) 2003.

Section 8 ***The four primary bodies defined in terms* of *the surfaces of the four canonical solids (55c7-57d6), toward the resolution of the problem of infinite kosmoi; the first argument, based on the fundamental passage 57d7-58a2, that the incommensurable dyad of primary earth PE and primary water PW constitutes, with the aid of the ratios PW to primary air PA = 5/2 and to primary fire PF = 5/1, the Third Kind, substituting the intelligible dyad, as the cause of all sensibles***

Let us reiterate that Plato, as explained in Sects. 4 and 5, is *obliged* (εἰσαναγκάζειν, 49a3), for the sole reason of ensuring the One Kosmos, to introduce in 48e-49a the Third Kind/Receptacle. In this section, we introduce *the four primary bodies*, defined by Plato by means of the corresponding surfaces of the four canonical solids (8.2), and present our interpretation of passage 57d7-58a2 (in 8.4-6), a fundamental passage that has not been understood properly so far, according to which the incommensurable, infinite anthyphairetic dyad of primary earth PE to primary water PW, aided by the commensurable dyads PW/PA = 5/2 and PW/PF = 5/1 (where PF is primary fire and PA primary air), is the *Third Kind*, coinciding with the Receptacle and *substituting* the intelligible dyad IE, IF, as *the cause and generator* of the sensible bodies.

Having prepared the ground, with the geometry of the (surface of the) four canonical solids and their commensurability or incommensurability, in 53c4-55c6, described in Sects. 6 and 7, Plato now is about to introduce, in 55d7-56b6, his most crucial *definition of the primary bodies* (ἄκρατα καὶ πρῶτα σώματα, 57c7).

8.1 *The seeming puzzle of Plato's return to the problem of infinite Kosmoi in* ***55c7-d6***

But precisely after 55c6 and before the definition of the primary bodies starting at 55d7, Plato interposes a seemingly unrelated paragraph 55c7-d6, in which he returns to the question he had first posed in 31a-b (passage given in Sect. 3) on whether there is one kosmos or infinite kosmoi.

Cornford 1937, finds the passage "extremely puzzling," because "There is nothing in the previous context to suggest a plurality of worlds…" (p. 220). "the ancients,…have found the passage as obscure as it is to us." (p. 221). Gregory 2001, pp. 42–43, calls the passage "rather puzzling."

But our analysis shows that the reopening of the question and problem on infinite kosmoi at this point is quite appropriate and justified, because Plato *exactly at this point*, with the definition of the primary bodies he is about to give, aims to succeed to get rid of the infinite Kosmoi and ensure the desired One Kosmos.

8.2. *The* ***definition*** *of the four primary and uncompounded four bodies (ἄκρατα καὶ πρῶτα σώματα, 57c7)*

> To [primary] *earth* let us assign the cubical kind (κυβικὸν εἶδος); 55d8

> Wherefore, we are preserving the image account (τὸν εἰκότα λόγον διασῴζομεν) when we assign this figure [*cube*] to [primary] *earth (γῇ)* 55e7-56a1

> Thus, in accordance with the right and the image (κατά τὸν εἰκότα) account, that solid which has taken the kind (εἶδος) of a *pyramid* shall be the element and seed of [primary] *fire* (πυρὸς στοιχεῖον καὶ σπέρμα); the second in order of generation [*8hedron*] we shall affirm to be [primary] *air (ἀέρος),*
> and the third [*20hedron*] [primary] *water (ὕδατος).* 56b3-6

Plato calls these four bodies the *uncompounded primary bodies* (ἄκρατα καὶ πρῶτα σώματα, 57c). There are some heuristic arguments in favor of these assignments, but in reality they form a

Definition
primary earth PE = the surface of the cube = 24A,
primary fire PF = the surface of the pyramid = 24B,
primary air PA = the surface of 8hedron = 48B, and
primary water PW = the surface of the 20hedron = 120B.

Thus the primary bodies are defined as *purely geometrical rectilinear areas* (55d7-56b6, *57c7-d6*).

8.3. *Convenient modifications of the primary bodies (57c7-d6)*

By definition PE = 24A. But Triangle A can be divided into two triangles of the same type, and we can continue dividing as long as we wish. Thus $A = 2^{n\cdot}A'$, where A' is a triangle of the same form, similar to A, and n is any natural number. Thus

$$PE = 24.2^{n\cdot\cdot}A'.$$

Also by definition PW = 120B. But Triangle B can be divided into three triangles of the same type, and we can continue dividing as long as we wish. Thus $B = 3^{m}B'$, where B' is a triangle of the same form, similar to B, and m is any natural number. Thus,

$$PW = 120.3^{m\cdot\cdot}B'.$$

Similar remarks hold for PA, PF. The incommensurability (and in fact periodicity of anthyphairesis) of PE to the other three primary bodies and the commensurability of the three, minus PE, primary bodies are not affected by considering triangles A and/or B greater or smaller in the above sense. This is the content of *Timaeus 57c7-d6.*

8.4. *We interpret the fundamental passage 57d7-58a2 according to which the inequality is the cause of all motion:*

The inequality refers to the inequality of the sides of Triangle B, and in fact to the incommesurability of the dyad Equality of Triangle A to inequality of Triangle B; it is the cause of all sensible motion, substituting for the intelligible Being.

There results the interpretation of the Receptacle in terms of the primary bodies, and a first argument identifying the Third Kind in terms of the primary bodies.

8.4.1. *The fundamental passage Timaeus 57d7-58a2*

> Now, unless we can arrive at some agreement concerning Motion and Rest,
> as to how and under what conditions they are generated,
> our subsequent argument (λογισμῷ) will be greatly hampered (ἐμποδὼν).
> The facts about them have already been stated in part;
> but in addition thereto we must state further the following, that
> motion never consents to exist in a state of *non-opposition* (ἐν μὲν ὁμαλότητι).
> For it is difficult, or rather impossible,
> for that which is to be moved (τὸ γὰρ κινησόμενον) to exist without that which is to move (τοῦ κινήσοντος), or that which is to move without that which is to be moved;
> but in the absence of [the dyad of] these there is no motion,
> and that these should ever be unopposed (ὁμαλὰ) is a thing impossible.
> Accordingly, we must always (**ἀεὶ**) place
> rest in the state of non-opposition (ἐν ὁμαλότητι), and
> motion in the state of opposition (εἰς ἀνωμαλότητα); and
> *the cause (αἰτία)* of the nature of the state of opposition (τῆς ἀνωμάλου φύσεως) is *inequality (ἀνισότης)*. We have already explained the generation of *inequality*. 57d7-58a2

Thus for *motion* (κίνησις) to be possible, there must be
a dyad in a state of opposition (εἰς *ἀνωμαλότητα*), namely a dyad consisting of
that part which is to move (τὸ κινῆσον), namely the active part of the motion, and
that part which is to be moved (τὸ κινησόμενον), namely the passive part of the motion;
the cause of a dyad in opposition, and thus of motion, is *inequality* (*αἰτία* δὲ ἀνισότης αὖ τῆς ἀνωμάλου φύσεως, 58a1).

Beginning with Cornford, scholars have seriously misunderstood the meaning of inequality, of state of opposition, and of inequality being the cause of opposition, in this fundamental passage.[10] Because of this misunderstanding, scholars failed to realize that passage 57d7-58a2 provides an understanding of the Third Kind, in particular identifies the Receptacle and the primary bodies. We now examine this passage.

[10] Cornford 1937, p. 240: "Now, however, the bodies have received their shapes, and these shapes are unequal in size in two ways: each kind of body has a particle of a different size from the rest, and there are several grades of each kind. This may be what is meant by inequality as the cause of heterogeneity."

Gregory and Waterfield 2008, p. 146: "presumably Plato is thinking of the 'inequality' between all the different elementary triangles."

As the term "inequality" does not appear at all in 57c7-d6, these are arbitrary interpretations, making it impossible to appreciate the fundamental role of incommensurability in Plato's Third Kind.

8.4.2. *Inequality, in passage 57d7-58a2, interpreted as anthyphairetic infinity and incommensurability*

Essential help comes from Aristotle and Simplicius.

Aristotle in *Physics* 201b18-26 states that the cause of platonic motion is *inequality* (ἀνισότητα), adding the *Not-Being* (μὴ ὄν, 201b20) and the *indefinite* (ἀόριστόν, 201b24) (ἑτερότητα καὶ *ἀνισότητα* καὶ *τὸ μὴ ὂν* φάσκοντες εἶναι τὴν κίνησιν; *ἀόριστόν* τι δοκεῖ εἶναι ἡ κίνησις);

Eudemus, quoted by Simplicius *In Physics* 431, 6–12, adds to the platonic cause of motion, next to inequality, not-Being, and opposition, also the indefinite dyad *the great and small* (τὸ μέγα καὶ μικρὸν) ("Πλάτων δὲ τὸ μέγα καὶ μικρὸν καὶ τὸ μὴ ὂν καὶ τὸ ἀνώμαλον καὶ ὅσα τούτοις ἐπὶ ταὐτὸ φέρει τὴν κίνησιν λέγει").

Simplicius, *In Physics* 430, 11–12, clarifying Aristotle, points out that Plato identifies the *Not-Being* (μὴ ὄν) as the cause of motion in the *Sophistes* (καὶ δέ, φησί, τὴν κίνησιν ὁ Πλάτων λέγει ἐν Σοφιστῇ); in 453, 25–455, 14 he connects the great and the small (453, 27) with *the indefinite dyad* (ἀόριστος δυάς, 453, 26), and *the infinite* (ἄπειρον, 453, 27–28). It becomes clear from these passages that inequality, the cause of platonic motion, is a *Philebean infinite* (*Philebus* 23b5-25e2).

But now, the Philebean Infinite has been interpreted by Negrepontis 2005, (B), (D), (E), as being the *anthyphairetic infinity*, an interpretation fully supported by Proclus.[11]

We note that Aristotle and commentators on his work, even if strongly critical of Plato (e.g., Simplicius, *In Physics* 431, 6–12, cites Eudemus stating that it is preposterous (ἄτοπον) and claiming that it is ridiculous (γελοῖον) for Plato to maintain that the *cause* of motion is inequality), nevertheless fully understand and describe faithfully Plato's views.

In sum, according to the crucial comments by Aristotle, Eudemus, and Simplicius, and our interpretation, the platonic cause of motion, identified as *inequality*, is *anthyphairetic infinity*, and thus (by Proposition X.2 of the *Elements*) *incommensurability*.

8.4.3. *The inequality in passage 57d7-58a2 refers to the inequality of the sides of Triangle B; it is an Incommensurability in relation to, and completing, the Equality of Triangle A, as shown in Sect. 7.*

In order to clarify the meaning of "inequality," we must examine all the earlier (i.e., before 58a2 in the *Timaeus*) occurrences, where Plato, as he himself states, has dealt with inequality. The prior occurrences of words with the root *ἀνισ-* are in 53d3,

[11] "and if [Platonic, Philebean] infinite did not exist (καὶ τῆς μὲν ἀπειρίας οὐκ οὔσης),
all magnitudes would be commensurable with each other (τά τε μεγέθη πάντα σύμμετρα ἂν ἦν), and
there would be nothing irrational (οὐδὲν ἄρρητον) nor "alogon" (οὐδὲ ἄλογον)"
Proclus, *Comments to the First Book of Euclid's Elements* 6, 19–21 [our translation]

53d4, 54c2, and 55e5, and they all have to do with the inequality of the sides in the right angle of the Triangle B.

Now inequality, on the one hand, has been interpreted in 8.4.2 as an incommensurability and an anthyphairetic infinity and, on the other hand, as the inequality of the sides in Triangle B. But incommensurability makes sense only for a dyad, not for a single entity, such as Triangle B. The parallel that Aristotle and his commentators draw of inequality with *Sophistes*' Not-Being (8.4.2) is helpful. The Not-Being *completes* the Being, and together they form an intelligible dyad, hence, according to Sect. 1, a dyad in philosophic infinite anthyphairesis.

Thus the "inequality" of Triangle B completes the "equality" of Triangle A, and together they form an incommensurable dyad,

as Not-Being completes Being in the *Sophistes*, and

as Being completes One in the second hypothesis of the *Parmenides*.

Thus, the claim in passage 57d7-58a2 that

Inequality is a state of continued (anthyphairetic) opposition (ἀνωμαλότης)

is equivalent to the statement that

the dyad Triangle A and Triangle B is incommensurable.

Indeed, inequality of Triangle B produces anthyphairetic infinity and *incommensurability* when (anthyphairetically) opposed to Triangle A. We recall that the incommensurability of Triangle A, B was hinted by Plato, and we established it in Sect. 7; now, we see that it reappears in 57d7-58a2 with fundamental importance, as the cause of sensible generation and motion.

8.4.4. *Plato's choice for the dyad Equality, inequality, the cause and generator of all sensible bodies in 57d-58a, is the dyad primary earth PE to primary water PW.*

The statement in 57d-58a that *the cause* of every motion is inequality, namely as explained in the previous Sect. 8.4.3, the Incommensurability of Triangle A to Triangle B, according to our interpretation, is remarkable (This is exactly what the Aristotelian Eudemus calls preposterous and ridiculous).

But how can the incommensurability of the dyad Triangle A to Triangle B be the cause of all sensible motion?

The cause for all motion that Plato has in mind is not necessarily the dyad Triangle A to Triangle B; besides the dyad Triangle A, Triangle B itself, certain dyads of primary bodies exhibit such incommensurability.

Since each of the dyads <PW, PA>, <PW, PF>, and <PA, PF> consists, in any conceivable combination of sizes, of entities that contain *only Triangle B,* it cannot constitute an incommensurable dyad, and hence it must be rejected as the cause of generation or motion.

But according to the Main Proposition of Sect. 7, each of the remaining three dyads of primary bodies

PE, PW; PE, PA; and PE, PF,

is inextricably linked with inequality, is *incommensurable* in the sense of Equality versus inequality, in fact in periodic anthyphairesis, and thus is a possible candidate for the cause for the generation of motion.

Thus, in total there are four conceivable dyads for which the opposition inequality versus Equality materializes, namely

$$< \text{Triangle A}, \text{Triangle B} > ; < \text{PE}, \text{PF} > ; < \text{PE}, \text{PA} > ; \text{and}, < \text{PE}, \text{PW} > .$$

The first dyad, the geometrical dyad Triangle A, Triangle B itself, should be excluded. We might base this exclusion on the fact that we expect the cause of sensible motion to be some dyad with fundamental physical significance; and also because the dyad of triangles includes many other instances of incommensurabilities beyond those produced by the "physically meaningful" primary bodies; but the main reason for excluding this dyad is the fact that, as we shall see in Sect. 10, *only* the primary bodies *participate* in the intelligible, *not* these triangles.

We are thus naturally directed to seek the all-important dyad/cause among the three dyads that may be formed from the four *primary bodies*.

At this point however we must take into account the restriction that Plato sets early: primary earth cannot interact directly with primary fire (and with primary air) but only through the intermediary of primary water.

> Hence, in beginning to construct the body of the World,
> God was making it of fire and earth (ἐκ πυρὸς καὶ γῆς).
> But it is not possible that two kinds alone should be conjoined (καλῶς συνίστασθαι)
> without a third; for there must needs be some intermediary bond (δεσμὸν *ἐν μέσῳ*)
> to connect (συναγωγὸν) the two (ἀμφοῖν) 31b6-c2

> what conjoins (συναρμόττουσιν) solids is never one intermediary term alone but always two
> *(μία μὲν οὐδέποτε, δύο δὲ ἀεὶ μεσότητες).*
> Thus it was that in the midst (ἐν μέσῳ) between fire and earth God set water and air 32b2-4

Passage 60e4-61a1, in Sect. 9, Appendix 2, is far more explicit, confirming that there is no direct interaction of PE with PA or PF, but only through PW.

Thus primary earth PE is in direct contact and interaction *only* with primary water PW, and *not* with PA or PF. Interaction between PE and PA or PF is possible only indirectly as a *composition* of the interaction of PE with PW followed, by the use in some form of the commensurable ratios PW/PA = 5/2 and PW/PF = 5/1. It follows that the dyad materializing the incommensurability of Equality versus inequality that is the cause for all motion, according to passage 57d-58a, can only be the dyad PE, PW of primary bodies.

8.4.5. *The sense in which* ***the dyad PE, PW*** *is* ***the "cause of motion"*** *in passage 57d-58a*

In order to understand the use of this term "cause for motion," let us note that,

on the one hand, as we saw in Sect. 2, in pre-*Timaeus* theory of sensibles, a sensible is fully described and known by an initial *finite* segment of the *infinite*

anthyphairesis of the intelligible dyad <IE, IF> (so that a sensible body is the end result of an initial *finite* segment of the *infinite* intelligible anthyphairesis of IE to IF, namely *a sensible body is generated* by an initial finite segment of the intelligible anthyphairesis of IE to IF);

on the other hand, according to traditional, pre-*Timaeus* Plato's dialectics, e.g., in *Phaedo* 100c, the intelligible Being is *the cause* of every sensible body participating in it (Sect. 2.4).

But an initial finite segment of an (intelligible) anthyphairesis describes a motion, exactly as stipulated in the 57d-58a passage:

The first step of the motion is realized by the initial dyad <IE, IF>, the part IF as the active part (that which moves) of the motion, and the part IE as the passive (that which is moved); the anthyphairesis of this dyad generates the part IE_1, and the second step of the motion is realized by the dyad <IF, IE_1>, with IE_1 as the active (moving) part and IF the passive (moved), and so on.

After a finite, say n, number of steps, we will have completed a motion, whose end product is *the generation* of a sensible body, according to Sect. 2; and furthermore a change from one sensible, say generated at stage n, to another sensible, say generated at a later stage m, is also described by a motion.

Thus, the intelligible Being, in fact the intelligible dyad with its *infinite* anthyphairesis, is *the cause* of all sensible bodies that participate in it, and of the motions that generate them and transform one of them into the other, all completed in an initial *finite* number of steps of the infinite intelligible anthyphairesis.

We expect that the meaning of *the cause* of all motion that is claimed in 57d-58a for the inequality, but eventually, following our argument in 8.4.4, for *the dyad PE to PW*, is analogous; in other words, we expect that every sensible body will be fully determined and known by an initial *finite* segment of the *infinite* anthyphairesis of the dyad PE to PW.

8.4.6. *It follows from 57d-58a that*

the generation of the sensible bodies in the Receptacle (49a-57c) is ***caused*** *by the incommensurability of the primary bodies and is equivalent to the generation of the sensibles by means of "diakena" and "hedrai" (58bff);*

the ***Third Kind*** *consists of the incommensurable dyad primary Earth PE, primary Water PW, assisted with the commensurable ratios PW/PA = 5/2 and PW/PF = 5/1.*

It follows, from passage 57d7-58a2, that every motion, hence the motion of the Receptacle (by which all sensible bodies are generated), is governed by the incommensurability of the primary bodies. Indeed:

First, the motion of the Receptacle mentioned in 57c2-6, and in fact every motion of the Receptacle mentioned in 49a-57c, *before* the crucial passage 57d-58a, e.g., 52e1-5, is really a motion involving not just the Receptacle, since every motion is possible only if there is a dyad of opposites, but a dyad, and this dyad can only be the Receptacle & its Content.

Second, *the cause* of the motion of the Receptacle & Content is, as is of every motion, the inequality, which, according to the arguments developed just above, takes the form of the *incommensurable* dyad of primary bodies PE, PW.

Third, by our interpretation of the term "cause," the sensible generated by the motion of the Receptacle & Content is fully described by a *finite* initial segment of the *infinite* anthyphairesis of PE to PW.

On the other hand, every motion described *after* the passage 57d7-58a2 never refers to the Receptacle, but to the "diakena" of the greater primary body, and is in fact described as the motion of a dyad of primary bodies; this motion has also the same cause, namely the *incommensurable* dyad PE, PW, and is thus fully described by a *finite* initial segment of the *infinite* anthyphairesis of PE to PW.

These remarks, depending on the fundamental passage 57d-58a and our interpretation of inequality and cause, lead to the identification of the Receptacle, before passage 57d7-58a2, and the "diakena" of the primary bodies, after passage 57d7-58a2.

Passage 57d7-58a2 thus serves as the connecting link between the description of the Third Kind as Receptacle (49a-57c), mentioned at 57c3 for the last time, and as "diakena" and "hedrai" (58b -62a ff), mentioned at 58a4 for the first time, of the greater primary body (For the relation between "diakena" and "hedrai," see Sect. 9, Appendix A).

Thus the correct interpretation of passage 57d7-58a2, something not done before, shows that the mysterious Receptacle is fully accounted by the action of the primary bodies.

Receptacle	*"diakena" of primary body*	*"hedrai" of primary body*
49a6, 50b6, d3, e3, 51a5, 52a2, d5, d6 ff, 57c3		
57d7-58a2		
	58b3, b5	
		59d6, 60c4
	60e5, 61a5, b1, b4	
		62a8
		[79b4, b6, 80c5]

But our interpretation of the fundamental passage 57d-58a leads us close to an understanding of the Third Kind: Indeed, what would be a better way to describe the Third Kind than by the requirement that it substitutes (for) the intelligible as *the cause* and generator of all sensible bodies.

Thus *the Third Kind* consists of the four primary bodies, in the following arrangement: The principle constituent of the Third Kind is the incommensurable dyad of primary earth PE to primary water PW, substituting (for) the intelligible dyad IE, IF, aided by the auxiliary commensurable dyads PW/PA = 5/2 and PW/PF = 5/1.

The dyad PE, PW generates all waterlike or earthlike sensibles, as initial anthyphairetic approximations of the anthyphairesis of PE to PW. But the airlike and firelike sensibles are in fact completely determined and generated as well by the

dyad PE to PW, if we take into account the auxiliary ratios PW/PA = 5/2 and PW/PF = 5/1.

We will confirm and understand in depth this description of the generation of all sensibles from the primary bodies in Sect. 11 (The exact description of the Third Kind is given in Sects. 10 and 11).

Section 9 *The description of the generation of the Timaeus sensibles in terms of the "diakena" of the primary bodies in 58a4-c2, 61a7-b3 is equivalent to the corresponding description in terms of the Receptacle in 50a-51a, 52d4-53a6, and 57a7-c6, revealing the equivalent descriptions of the Third Kind by the "diakena" of the primary bodies and by the Receptacle, and the mathematical origin of the term Receptacle.*

From our interpretation of passage 57d-58a, in Sect. 8, we have concluded that the Content is a mass of smaller primary bodies that enter the Receptacle, a mass of greater primary bodies, thus showing that the primary bodies and the Receptacle are equivalent descriptions of the Third Kind.

In the present section, we provide a second, more detailed, argument showing the equivalence of the Receptacle and the primary bodies. This argument can be sketched as follows:

In 58a4-c2, Plato describes the generation of the sensibles and their motions in terms of the "diakena" of primary bodies (Sect. 9.1).

This process consists in four steps, as follows:

[1]. A mass of the small primary body, say PW, enters the "diakena" of a mass of the great primary body, say PE.
[2]. In fact not just enters, as in [1], but fills, leaving not even one part empty.
[3]. The result of [2] is either that the great consolidate the small, making the defeated small dissimilar to themselves and similar to the victorious great, or that the small disperse the great, making the defeated great dissimilar to themselves and similar to the victorious small, forming in both cases a sensible body, in which the defeated stays together with the victorious in an entity both one and two (or "confounded" dyad, cf. 11.4.1 below).
[4]. The sensible thus formed by [3] moves to the proper place of the victorious part.

This elaborate process of four steps is essentially repeated in with the "diakena" of the primary bodies replaced by the Receptacle (Sect. 9.2). The four steps, by means of which the generation of the sensibles and their motion takes place in and by the Receptacle, are so uncannily similar to the four steps, by means of which the generation of the sensibles and their motion takes place in and by the primary bodies, that the conclusion that the Receptacle and the primary bodies are equivalent descriptions of the Third Kind is inescapable. We thus identify the Content with the smaller primary body and the Receptacle with the "diakena" of the greater primary body (In the *Appendix*, we show that the "diakena" of a primary body further coincide and are equal to the faces/hedrai of that primary body).

9.1. *The generation of a sensible body as a dyad of a small primary body entering and filling the "diakena" of the greater primary body, in such a way that*

either the great body consolidates the small body, the great body is *minimum for the given small body, the small body becomes similar to the great body and dissimilar to itself, and*

the dyad as a unit moves to the place of the great body

or the small body disperses the great body, the small body is maximum for the given great body, the great body becomes similar to the small body and dissimilar to itself, and

the dyad as a unit moves to the place of the small body.

9.1.1. [1] *A mass of the smaller* ***primary*** *body enters the* ***"diakena"*** *of a mass of the greater* ***primary*** *body* (58a7-b6).

Wherefore (διὸ δὴ),
[primary] *fire* most of all has permeated all things (εἰς ἅπαντα *διελήλυθε* μάλιστα),
and in a second degree [primary] *air*, as it is by nature second in fineness,
(ἀὴρ δὲ δεύτερον, ὡς λεπτότητι δεύτερον ἔφυ);
and so with the rest (καὶ τἆλλα ταύτῃ)
for those [primary bodies] that have *the greatest constituent parts*
(τὰ γὰρ *ἐκ μεγίστων μερῶν* γεγονότα)
have the *largest empty place* left in their construction
(μεγίστην *κενότητα,* 58b3, ἐν τῇ συστάσει παραλέλοιπεν),
and those that have *the smallest* (τὰ δὲ σμικρότατα) [constituent parts]
the least (ἐλαχίστην) [empty place].
58a7-b4
. . .
Therefore, when *small* [primary] bodies are placed beside *great* [primary bodies]
(σμικρῶν οὖν παρὰ μεγάλα τιθεμένων) 58b6

Thanks to 58a5, according to which the passage in question refers to the Kinds (τὰ γένη, 58a5) which were *comprehended (συμπεριέλαβεν)* by the sphere of the World, these Kinds are uniquely determined as the four *primary bodies* (cf. *σφαίρᾳ περιλαβεῖν*, Book XIII. of the *Elements*), and thanks to the fundamental passage 57d7-58a2, analyzed in Sect. 8, the masses in the present passages are masses of *primary bodies*.

We must *not* conclude from passage 58a7-b6 that the particles of primary fire PF or primary air PA can enter and fill the "diakena" of primary earth PE; in fact, this is explicitly excluded in passage 60e4-61a1.

Masses of *[primary] earth* (γῆς ὄγκους) are
not dissolved (οὐ τήκει) by *[primary] fire or [primary] air*;
because their particles are smaller (σμικρομερέστερα πεφυκότα),
than the [primary] earth's "diakena",
so that, having plenty of room to pass through (διὰ πολλῆς εὐρυχωρίας ἰόντα),
not violently (οὐ *βιαζόμενα*),
they do not dissolve (ἄλυτον) [primary] earth but leave it undissolved (ἄτηκτον)
whereas the particles of *[primary] water*, having greater parts (μείζω. . . μέρη),

make their exit through violently (*βίαιον* ποιούμενα τὴν διέξοδον)
and so break (λύοντα) the [primary] earth and dissolve (τήκει) it.
[Primary] earth, then,
namely earth that has not been formed violently into sensible earth (**ἀσύστατον** ὑπὸ **βίας**),
is dissolved in this way by [primary] water only, 60e4-61a1

Thus, the typical case is when the great body is primary earth PE and the small body is primary water PW (The other possibilities will be examined in Sect. 11). We express mathematically the passage by an inequality as follows:

A mass M.PW of M particles of primary water enters into the "diakena" of a mass N.PE of the greater primary earth (where M and N are some natural numbers), so that

$$\text{M.PW} \leq \text{N.PE}.$$

Now we note that we cannot possibly have Equality, since, according to Sect. 7, PE and PW are incommensurable; thus, in fact

$$\text{M.PW} < \text{N.PE}.$$

for some natural numbers M, N.

9.1.2. [2] *The **smaller primary body** enters, fills quite fully, and tightens **the "diakena" of the greater primary body** in such a way that either the smaller primary body is Maximum, or the greater primary body is Minimum* (58b4-5,a7, 617b3).

Thus the process of *tightening* (ἡ δὴ τῆς *πιλήσεως* σύνοδος)
compresses together (συνωθεῖ)
the small [primary] bodies (*τὰ σμικρὰ*) into (*εἰς*)
the empty places (τὰ διάκενα, 58b5) of the great (τῶν μεγάλων) [primary bodies]. 58b4-5

In passage 58b4-5, the process of tightening and compressing sets the mass of small primary body in the "diakena" of the great primary body.

We now come to an important and misread passage.

and thus it allows not even one part (οὐδεμίαν)
of empty place (κενὴν χώραν) to be left (ἐᾷ λείπεσθαι) 58a7.

The key expression here is

"οὐδεμίαν κενὴν χώραν" 58a7.

We claim that it should be rendered,
not as "no empty space," as it is customary,
but more literally and separately, as two words,
as "not even (οὐδὲ) one (μίαν) empty space."

There is an analogous passage with the terms *οὐδὲν* and *μηδὲν* in the *Parmenides* 144c2-6:

—What about this: Is there any among them which
is part of being (ἔστι μὲν μέρος τῆς οὐσίας), and yet not one **(οὐδὲν)** part?
— ᾽How could there be?
—Rather, I suppose, since it is, so long as it is
it must always be some *one (ἕν) thing*;
it cannot be *not one (μηδὲν δὲ ἀδύνατον)*. *Parmenides* 144c2-6
(Allen 1997, p. 28, modified by the author)

Here (οὐδὲν) and μηδὲν make sense only if they are rendered more literally and separately, as two words, as not (οὐδ) one (ἐν), and as not (μηδ) one (ἐν).

It is emphatically clear that both terms (οὐδὲν, μηδὲν) cannot be rendered as "nothing," but only as "not even one" (cf. Negrepontis TA).

According to our interpretation of "οὐδεμίαν κενὴν χώραν," "not even one empty space is left out." The passage, according to this interpretation, states that

namely, not even one part of the smaller primary body PW can be added,

namely, we cannot do with a greater mass of small body than M.PW,

namely, adding even one part PW to the mass of smaller body M.PW, and obtaining thus the mass (M+1).PW, this mass cannot be entered into the greater mass.

With this interpretation of *"οὐδεμίαν κενὴν χώραν,"* we can now connect in a satisfying way with the tight double inequality corresponding to Dispersion, in Sect. 4.

Indeed, let us assume, as in 9.1.1, that a mass M.PW of primary water enters into the "diakena" of a mass of the greater primary earth N.PE, so that

$$\text{M.PW} < \text{N.PE}.$$

The mathematical inequality can now be completed, in accordance with our present interpretation,

not even one part of *the smaller primary body*, namely of M.PW, can be added;

to obtain the following double mathematical inequality:

$$\text{M.PW} < \text{N.PE} < (\text{M} + 1).\text{PW}.$$

We can express this situation by saying that the mass of the small primary body is *Maximum* for the given mass of the great primary body.

The filling and forcible tightening **(***βίᾳ συμπεπιλημένα***)** of the "diakena" of a mass of particles of primary earth PE with a mass of particles of primary water PW in the 61a7-b3 passage confirms the interpretation we have just given.

As regards the classes of bodies (τὰ δὴ τῶν σωμάτων),
which are *compounds (συμμείκτων)* of earth and water (ἐκ γῆς τε καὶ ὕδατος)
so long as the water (ὕδωρ) occupies (κατέχῃ)
the interspaces of earth (τὰ τῆς γῆς διάκενα) which are
forcibly tightened (βίᾳ συμπεπιλημένα),

the portions of water (τὰ μὲν ὕδατος μέρη) which approach from without (ἐπιόντα ἔξωθεν)
find no entrance (εἴσοδον οὐκ ἔχοντα),
but flow round the whole mass (περιρρέοντα τὸν ὅλον ὄγκον)
and leave it undissolved (ἄτηκτον εἴασεν). 61a7-b3

But we now cannot fail to observe, with satisfied surprise, that this is the exact same double inequality we have obtained for the odd stage anthyphairesis of the dyad PE, PW.

We may now complete the picture by considering the dual case (it is not stated in the Timaeus for the "diakena," but it is hinted for the Receptacle, cf. 9.2.2 below): The mass of the great body is being filled quite fully by the mass of the small body in the sense that

not even one part of *earth*, N.PE, can be excluded;
this can only mean that

$$(\mathrm{N}-1).\mathrm{PE} < \mathrm{M.PW} < \mathrm{N.PE},$$

exactly the double tight inequality that corresponds to the even stages of the infinite anthyphairesis of PE to PW that we have found in Sect. 4.

We can express this situation by saying that the mass of the great primary body is *Minimum* for the given mass of the small primary body.

Thus, a mass of great primary bodies is filled quite fully by the mass of smaller primary bodies. We obtain the double tight inequalities

$(\mathrm{N}-1).\mathrm{PE} < \mathrm{M.PW} < \mathrm{N.PE}$, or $\mathrm{M.PW} < \mathrm{N.PE} < (\mathrm{M}+1).\mathrm{PW}$, respectively.

(equivalently, in convergent form,

$\mathrm{M/N} < \mathrm{PE/PW} < \mathrm{M}/(\mathrm{N}-1)$, or $\mathrm{M/N} < \mathrm{PE/PW} < (\mathrm{M}+1)/\mathrm{N}$, respectively).

These inequalities coincide with those obtained in the Basic Proposition of Sect. 4, where they were shown to be equivalent to a finite initial system of the infinite anthyphairesis of PE to PW of even or odd length, respectively, thus to a description of the *Timaeus* (waterlike or earthlike) sensibles bodies.

9.1.3. [3] *Interpretation of Dispersion and Consolidation in terms of the double inequalities of the basic Proposition in Sect. 4: the generation of the sensible bodies in the form of a dyad*

either in Dispersion (the smaller primary body is active, victorious)
or in Consolidation (the greater primary body is active, victorious),
the defeated taking the form of the victorious in both cases,
the sensible body consisting of the ***smaller and greater primary body****, as one body, moves to the proper place of the victorious body*
(58b6-7, 58d4-e2)

and the smaller (τῶν ἐλαττόνων) *disperse (διακρινόντων)* the greater (τὰ μείζονα)
while the greater (ἐκεῖνα) *consolidate (συγκρινόντων)* the smaller (τῶν μειζόνων) 58b6-7

It is clear from the very form of the double tight inequality

$$(\mathrm{N}-1).\mathrm{PE} < \mathrm{M}.\mathrm{PW} < \mathrm{N}.\mathrm{PE}$$

in Sect. 9.1.2 that

a mass of the great primary body of earth PE is the *active* and the *victorious* part,

the defeated mass of the small primary body of water PW becomes approximately *assimilated* to PE,

and thus we witness the *generation* of an *earthlike sensible body.*

The process, *Consolidation (σύγκρισις), is*, as we saw in Sect. 4, the remainder free representation of every first initial segment of an even 2n number of steps of the infinite anthyphairesis of PE to PW in terms of the generalized side and diameter numbers, namely the modern "convergents":

$$(\mathrm{N}_{2\mathrm{n}}-1).\mathrm{PE} < \mathrm{M}_{2\mathrm{n}}.\mathrm{PW} < \mathrm{N}_{2\mathrm{n}}.\mathrm{PE}.$$

It is clear from the very form of the double tight inequality

$$\mathrm{M}.\mathrm{PW} < \mathrm{N}.\mathrm{PE} < (\mathrm{M}+1).\mathrm{PW}$$

in Sect. 9.1.2 that

a mass of the small primary body of water PW is the *active* and the *victorious* part,

the defeated mass of the small primary body of earth PE becomes approximately *assimilated* to PW,

and thus we witness the *generation* of a *waterlike sensible body.*

The process, *Dispersion (διάκρισις), is*, as we saw in Sect. 4, the remainder free representation of every first initial segment of an odd 2n − 1 number of steps of the infinite anthyphairesis of PE to PW in terms of the generalized side and diameter numbers, namely the modern "convergents":

$$\mathrm{M}_{2\mathrm{n}-1}.\mathrm{PW} < \mathrm{N}_{2\mathrm{n}-1}.\mathrm{PE} < (\mathrm{M}_{2\mathrm{n}-1}-1).\mathrm{PW}.$$

We introduce the following notation:
$\boxed{\mathbf{PW}} < \mathbf{PE}$ to mean a dyad $\mathrm{M}.\mathrm{PW} < \mathrm{N}.\mathrm{PE}$ in Dispersion
$\mathrm{M}.\mathrm{PW} < \mathrm{N}.\mathrm{PE} < (\mathrm{M}+1).\mathrm{PW}$, generating a waterlike sensible
$\mathbf{PW} < \boxed{\mathbf{PE}}$ to mean a dyad $\mathrm{M}.\mathrm{PW} < \mathrm{N}.\mathrm{PE}$ in Consolidation
$(\mathrm{N}-1).\mathrm{PE} < \mathrm{M}.\mathrm{PW} < \mathrm{N}.\mathrm{PE}$, generating an earthlike sensible.

The kinds of [[*sensible*]] water ***(τὰ δὲ ὕδατος)*** are, primarily, two *(διχῇ),*
the one being the *liquid* (τὸ μὲν ὑγρόν), the other the *fusible* (τὸ δὲ χυτὸν) kind.
Now *the liquid (ὑγρὸν)* kind, inasmuch as it partakes of
those small (σμικρά) *unequal* (*ἀνίσων*) particles of [primary] water,
is *mobile* both in itself and by external force
owing to its *state of opposition* (διὰ τὴν ἀνωμαλότητα)
and the shape of its *figure* (τὴν τοῦ σχήματος ἰδέαν).
But the other *(τὸ δὲ)* [[*fusible (χυτὸν)*]] kind, which is composed of
large and *unopposed* (ἐκ μεγάλων καὶ ὁμαλῶν) particles [of primary eart

is more *stable* than the first and is *heavy*,
being solidified (πεπηγὸς) by its *state of non-opposition (ὁμαλότητός)* 58d4-e2

It is clear that
the "liquid" waterlike kind consists of a dyad $\boxed{\text{PW}} < \text{PE}$ in Dispersion, while
the "fusible" earthlike kind consists of a dyad $\text{PW} < \boxed{\text{PE}}$ in Consolidation.

We note that most scholars believe that both liquid and fusible waters are just mixtures of masses of only primary water PW in various sizes. The list of examples of the "fusible waters" (χυτὰ ὕδατα) is revealing: gold (χρυσὸς), adamant (ἀδάμας,) bronze (χαλκὸς), rust (ἰὸς) (59a8-c5), and the species of stone (λίθων εἴδη) (61b7-c1); it is simply impossible to accept that Plato believes gold, stones, etc. to consist only of water!

9.1.4. [4] *Motion of sensibles to their proper spaces* (58b8-c2)

they all shift (μεταφέρεται) up and down (πάντ' ἄνω κάτω)
towards their own proper *spaces* (πρὸς τοὺς ἑαυτῶν *τόπους*);
for the change in their several sizes (μεταβάλλον γὰρ τὸ μέγεθος ἕκαστον)
causes their position in *space* also to change (καὶ τὴν *τόπων* μεταβάλλει στάσιν) 58b8-c2

9.2. *The generation of a sensible body as a dyad of a Content entering and filling the Receptacle, in such a way that*

either the Receptacle consolidates the Content, the Receptacle is *minimum for the given Content, the Content becomes similar to the Receptacle and heavy, and*
the dyad as a unit moves to the place of the Receptacle
or the Content disperses the Receptacle, the Content is maximum for the given Receptacle, the Receptacle becomes similar to the Content and light, and
the dyad as a unit moves to the place of the Content.

9.2.1. *A mass of the Content enters, in fact filling quite fully and tightening, the mass of the* ***Receptacle*** (52d4-6, 52e1-3, 57a7-b1).

and that the Nurse of Generation (τὴν δὲ δὴ γενέσεως τιθήνην),
being liquefied (ὑγραινομένην) and ignified (πυρουμένην) and
receiving (δεχομένην) also the forms of earth and of air (τὰς γῆς τε καὶ ἀέρος μορφὰς),
52d 4-6

The *Nurse of Generation,* another name for the Receptacle, *receives (δεχομένην)* its Content, which is identified as forms of earth, water, air, and fire. From the interpretation of 57d-58a in Sect. 8, the Content is some primary body, as well. The fact that from the wording it appears that the Receptacle becomes similar to the Content is not clear at this stage, and we will come to this point later.

but owing to [the Receptacle] being *filled quite fully* (τὸ *ἐμπίμπλασθαι*) with powers (δυνάμεων) that are neither similar nor balanced (μήθ' ὁμοίων μήτε ἰσορρόπων) **52e1-3**

The Receptacle does not only receive the Content, but also is *filled quite full (ἐμπίμπλασθαι)* by the parts of the Content that enter the Receptacle. This is a central feature of the process of generation.

> the *smaller* particles, when *enveloped* (περιλαμβανόμενα) in the many *greater* ones'
> [the small enter into the large] **57a7-b1**

The mysterious Nurse of Generation/*Receptacle* of earlier passages, such as 50a-51a, 52d4-6, receives in general various bodies, while in the present passage 57a7-b1 which also deals with the Receptacle (it is a part of the longer passage 57a7-c6, and the Receptacle is mentioned in 57c3), it is clarified that the great body envelopes/receives the smaller: The smaller (*τά τε αὖ σμικρότερα*) parts, *the Content,* are comprehended *(περιλαμβανόμενα)* in the greater *(ἐν τοῖς μείζοσιν), the Receptacle.*

We may express mathematically by an inequality the passage as follows: A mass M.C of M particles of the Content enters into a mass N.R of the Receptacle (where M and N are some natural numbers), so that

$$M.C \leq N.R.$$

9.2.2. *The **Content** enters and fills quite fully **the Receptacle**, in such a way that (either the Content is Maximum for the given Receptacle or) the Receptacle is Minimum for the given Content* (52e2-3).

> in *not even one part of herself* (*κατ' οὐδὲν αὐτῆς*) [=the Receptacle] is
> she equally balanced (ἰσορροπεῖν) 52e2-3

We claim that

> "κατ' οὐδὲν αὐτῆς" in 52e2-3

should be translated,
not as "no part of herself," as it is customary,
but more literally and separately, as two words, as "not even (οὐδὲ) one (ἐν) part of herself" (as in 9.1.2 above).

According to this interpretation, the phrase states that
not even one part of the Receptacle (*κατ' οὐδὲν αὐτῆς*, 52e2-3) can stay balanced,
namely, not even one part of the Receptacle can be spared,
namely, we cannot do with a smaller Receptacle,
namely, subtracting even one part from the Receptacle, it cannot be Receptacle any more. Thus the Receptacle is *minimum for the given Content.*

The Receptacle is being filled quite fully by the Content, in accordance with 9.2.1, but now tells us in addition that the manner of filling is such that
not even one part of *the Receptacle*, namely of N.R, can be excluded;
this can only mean that

$$(\mathrm{N}-1).\mathrm{R} < \mathrm{M}.\mathrm{C} \leq \mathrm{N}.\mathrm{R},$$

exactly the double tight inequality that we have found in Sect. 4.

9.2.3. *Dispersion and Consolidation* (57c3-4)

> because of the motion of the Receptacle (διὰ τὴν τῆς δεχομένης κίνησιν), become *dissimilar to themselves* (τὰ δὲ ἀνομοιούμενα ἑκάστοτε ἑαυτοῖς) and similar to others (ἄλλοις δὲ ὁμοιούμενα) 57c3-4

The motion of the Receptacle, more precisely the motion of the dyad of opposites Receptacle & Content results

either in the Content becoming dissimilar to itself and similar to the Receptacle, and the Receptacle consolidates the Content, so that the Receptacle is the victorious part and the Content the defeated,

or in the Receptacle becoming dissimilar to itself and (approximately) similar to the Content, and the Content disperses the Receptacle, so that the Content is the victorious part and the Receptacle the defeated.

The defeated becomes approximately similar to the victorious body and stays with it**.**

9.2.4. *The motion of the generated sensible, Content & Receptacle, to the space proper to the victorious part*

> Moreover, it is owing to these affections (παθήματα) that they all interchange (διαμείβεται) their places (τὰς χώρας); for while the mass of each Kind keeps separate (διέστηκεν) in its proper space (κατὰ τόπον ἴδιον) because of the motion of the Receptacle *(διὰ τὴν τῆς δεχομένης κίνησιν)* yet those masses which from time to time become dissimilar to themselves and similar to others are moved (φέρεται), because of the shaking *(διὰ τὸν σεισμὸν)*, towards the space which is proper to those masses whereto they have been assimilated (τὸν ἐκείνων οἷς ἂν ὁμοιωθῇ τόπον). **57b7-c6**

9.3. *The equivalence of the Third Kind as Receptacle and as Primary bodies/ diakena,*

The mathematical origin of the term "Receptacle."

Relations of the descriptions of Receptacle as mother, nurse, with ancient similar descriptions of Earth (γαία).

9.3.1. *The Receptacle description of the generation of sensibles is strictly equivalent to the corresponding "diakena" of primary bodies description.*

Diakena of primary bodies First occurrence 58a (Sect. 9.1)	*Content & receptacle* Last occurrence 57c (Sect. 9.2)
[1] The small primary body enters the diakena of the great primary body 58a7-b6	[1] The content enters the receptacle 52d4-6, 52e1-3, 57a7-b1
The process of *tightening compresses* the small into the diakena of the great. Not even one part of the diakena is left empty 58b4-5,a7, 617b3	[2] Not only enters but fills fully, not even one part of the receptacle is left unbalanced 52e2-3
[3] The great consolidate the small; the small disperse the great 58b6-7, 58d4-e2	[3] *Dissimilar to themselves* and similar to others 57c3-4
[4] *Motion of sensibles to the proper spaces of the victorious part* 58b8-c2	[4] *The motion of the generated sensible, to the space proper to the victorious part* 57b7-c6

The four steps, by means of which the generation of the sensibles and their motion takes place in and by the Receptacle, are so uncannily similar to the four steps, by means of which the generation of the sensibles and their motion takes place in and by the "diakena" of the primary bodies, that the conclusion, that the Receptacle and the primary bodies are equivalent descriptions of the Third Kind, is inescapable.

9.3.2. ***Mathematical*** *origin of the term* ***Receptacle:*** *it reflects the* ***tightness*** *of the double inequalities.*

On the other hand, the steps in the process expressing the finite initial stages of the incommensurability of PE to PW in remainder-free expressions lead to the tight double anthyphairetic inequalities

$M.PW < N.PE < (M + 1).PW,$
[N.PE holds M.PW, but N.PE can hold nothing more]
$(N - 1).PE < M.PW < N.PE,$
[N.PE holds M.PW, but nothing less can hold M.PW]

that are eminently suitable, exactly because of their impressive tightness, to be termed in vivid and suggestive nonmathematical language as Content PW to Receptacle PE, in accordance with Aristotle's description of Receptacle (in Sect. 4). It

should be noted that the *tightness* is the predominant feature of these inequalities, a property expressed, besides the imagery Receptacle to Content, by a variety of expressions: "*tightens* (*σφίγγει*)" "the process of *tightening* (ἡ δὴ τῆς *πιλήσεως* σύνοδος)," "*compresses together (συνωθεῖ)*" *58a4-5*, and "allows not even one part (οὐδεμίαν) of empty place (κενὴν χώραν) to be left (ἐᾷ λείπεσθαι)" 58a7.

9.3.3. *The reason the Receptacle is called Mother (50d3) and Nurse (*τιθήνη *49a6, 52d5,* τροφὸς καὶ τιθήνη *88d6) is that the ultimate Receptacle of every sensible entity is primary Earth.*

According to our interpretation in 9.3.2, and our description of all sensibles in Sect. 11, *the ultimate Receptacle* of every sensible entity is primary earth PE. Primary water PW serves as final or intermediary Content in relation to PE, and as intermediary Receptacle in relation to primary air PA or primary fire PF.

But Earth, *the only female* of the four "elements" (water and fire are neutral, air masculine), is traditionally called *mother* and *nurse*

not only by various ancient authors (here is a small sample):

Γαῖα μάτηρ. Pindar, *Olumpia* 7,38
γῆ πάντων μήτηρ, Hesiodus, *Opera et Dies* 563
γαῖα μαῖα, Aeschylus, *Choephoroi* 43

In *Orphic Hymn* 63,5-16, earth is described as mother and as nurse/τιθήνη.

And all the living creatures (καὶ ζώιων πάντων), that earth (*γαῖα*), the godess *(θεὰ)*, mother (*μήτηρ*) nurses (*τιθηνεῖ*) ἐν κόλποισι *Orphic Hymn* 63,15-16

Cf. also γαῖα θεὰ μήτηρ *Orphic Hymn* 15,4; Γαῖα θεά, μῆτερ 26,1
but in fact also by Plato himself, who is repeatedly referring to Earth in exactly these terms:

ἡ ἡμετέρα γῆ τε καὶ *μήτηρ*, *Menexenus* 237e5-6
καὶ ἡ γῆ αὐτοὺς *μήτηρ* οὖσα ἀνῆκεν,
καὶ νῦν δεῖ ὡς περὶ *μητρὸς καὶ τροφοῦ τῆς χώρας Politeia* 414e2-6

In *Kratulos* 410b8-c3, Plato finds the etymology of earth as the place of generation, likening it to "mother":

The word γῆ (earth) shows the meaning better in the form γαῖα; for γαῖα is a correct word for *γεννήτειρα "mother,"* as Homer says, for he uses γεγάασιν to mean γεγενῆσθαι (be born). *Kratulos* 410b8-c3
[translated by Harold N. Fowler, modified by the authors]

Finally, in the *Timaeus* itself:

γῆν δὲ *τροφὸν* μὲν ἡμετέραν, *Timaeus* 40b8

These repeated occurrences suggest that Plato called the Receptacle "mother" and "nurse" precisely because the principal Receptacle, according to our interpretation, is primary Earth, and Earth was long connected with these terms. Thus these references of the Receptacle to "mother" and "nurse" in fact constitute one more argument in favor of our interpretation of the *Timaeus* Receptacle.

Appendix 9A *The identification of the "diakena" of the greater primary body with the "hedrai" and thus with the area of the faces of the greater primary body*

9A.1. In 53c-55c, where Plato introduces the canonical polyhedral (described in Sect. 6), the suffix -εδρον is never used to refer to the 4hedron (pyramid), 6hedron (cube), 8hedron, or 20hedron, contrary to the practice in the Theaetetean Book XIII of the *Elements* (where there are 77 references with this suffix). Furthermore, the face of a polyhedron is called βάσις, basis in the *Timaeus*; thus the square, consisting of two triangles A, declared a basis more stable (ἀσφαλεστέρα 55e3, 4; στασιμωτέρως 55e7) than the equilateral triangle consisting of two triangles B. However, the root hedr-/*εδρ-* does come up rather unexpectedly in 59d6-7, when the bases/faces of primary water, namely the equilateral triangles/triangles B, are declared less "hedral" (*ἑδραίους*) than those of earth, called "hedral" (*ἑδραῖον* 64b7) once more in 64b6-c6, thus introducing an indirect link between the faces and the term "hedra"

(rendered by Lamb again as less "stable," and thereby losing the connection).

> Also it [primary water] is soft owing to the fact that its bases (*βάσεις*), being less *stable* (*ἑδραίους*, 59d6) than those of earth, 59d6-7

In Greek, the text makes sense only if Plato has in the back of his mind the word "hedra" in place of the word "basis" he is using:

> the *hedra/basis* of the 20*hedron* is less *hedral* (*ἑδραία*) than the *hedra*/ basis of the 6*hedron*/ cube.

9A.2. In 52b1, Plato refers to the Receptacle, as

> providing *"hedra" (ἕδραν)* [room, Lamb] for all things that are generated

a statement that might simply describe the Receptacle as the seat or place of generation, with no association at all of the Receptacle with the face of a polyhedron (Same thing with 53a2). However, it is a fact that more "hedral" hedrai/faces, those of the 6hedron, make the best "hedra," in the sense of Receptacle, since it is the "hedra" of the greater primary body.

9A.3. *Identification of "hedrai" with "diakena"; identification of the "hedrai" of a primary body with the surface of the canonical polyhedron corresponding to that primary body*

But there are three occurrences of "hedrai" (59a3, 60c4, 62a8) *in the plural.*

It is tempting to consider that the empty places "diakena" of the great primary bodies are precisely the sum of the areas of the triangles constituting the great primary body, and that these are empty spaces in the sense that they wait to be filled by the corresponding triangles constituting the small primary dyad. Since the fundamental interaction between primary bodies is, as we have seen, the anthyphairesis of their surfaces, this interpretation is the only one that makes sense.

As we have seen, in Sect. 10, a mass of the small primary body tightens (σφίγγει, πιλήσεως) and compresses (συνωθεῖ) into the diakena of the great primary body:

> "tightens (σφίγγει) . . . all and allows no empty space (κενὴν χώραν) to be left", 58a7;
>
> "Thus the process of tightening (ἡ δὴ τῆς πιλήσεως σύνοδος) *compresses together (συνωθεῖ)* the small [primary] bodies (τὰ σμικρὰ) into (εἰς) *the empty places (τὰ διάκενα)* of the great (τῶν μεγάλων) [primary bodies]", 58b4-5;
>
> "primary water is *compressed* in the *"diakena"* of primary earth", 61a8;
>
> "the water (ὕδωρ) occupies (κατέχῃ) the "diakena" of earth (τὰ τῆς γῆς διάκενα), which are *forcibly tightened (βίᾳ συμπεπιλημένα)",* 61b1-2;
>
> "primary fire enters in the *"diakena"* of primary water", 61b3-4

Plato in several passages in the *Timaeus*, which we now examine, is exchanging the somewhat opaque term "diakena" with the term "hedrai," in plural; it should be obvious that "hedrai" cannot refer but to the "faces" of the polyhedron to which the "hedrai" belong.

> Again, since the [primary] fire, on exiting from the [*"hedrai"/faces* of the primary] water,
> does not exit into a void,
> *the* adjacent *[primary] air* (ὁ πλησίον ἀὴρ),
> being pressed (ὠθούμενος) into the *"hedrai"/faces* [[*places, Gregory*; abodes, Lamb]]
> previously occupied by fire (εἰς *τὰς τοῦ πυρὸς ἕδρας*, 59a3),
> *compresses (συνωθῶν)* the, still mobile, mass of [primary] water [with primary earth],
> and combines it (αὐτὸν) [the water and earth mass] with itself (αὑτῷ) [primary air].59a1-4

It is clear in passage 59a1-4 that "hedrai" is used instead of "diakena."

Primary air exits from the "diakena"/"hedrai" of primary water, and adjacent external primary air enters into and compresses these "diakena"/"hedrai" of primary water, previously occupied by primary fire.

> [primary air] being heavy,
> when pressed (*ὠσθεὶς*) and poured round
> the ["hedrai" of the] mass of [primary water mixed with] primary earth,
> it [the primary air] tightened forcibly (*σφόδρα ἔθλιψεν*) and compressed *(συνέωσέν*)
> it [the mass of primary earth and primary water] into the *"hedrai"/faces (εἰς τὰς ἕδρας)*
> [of primary water] from which [*the "hedrai"* of primary water] the new air was ascending;

and the [primary] earth compressed (συνωσθεῖσα) into [primary] water (ὕδατι) by [primary] air (ὑπὸ ἀέρος) so as to be indissoluble stone (πέτρα) is generated 60c2-6

It is clear in passage 60c2-6 that "hedrai" and "diakena" are used interchangeably.

Primary air enters, tightens, and compresses forcibly into the "hedrai," exactly as into the "diakena" of primary water, with the result that primary earth is compressed into primary water.

When [*mass of primary*] *water* with greater particles (μεγαλομερέστερα),
which surround the [primary earth] body,
enter (εἰσιόντα) into it [the *"hedrai"* of the primary earth],
they press out (ἐξωθοῦντα) the smaller [primary water] particles (τὰ σμικρότερα);
but as they [the greater particles of primary water] cannot enter into the *"hedrai (ἕδρας, 62a8)* [[room, Lamb; places, Gregory]] [of the smaller primary water],
they compress (συνωθοῦντα) the [primary] water (τὸ νοτερόν) within us,
so that instead of state of opposition *(ἐξ ἀνωμάλου)* and motion *(κεκινημένου)*
they produce immobility *(ἀκίνητον)*, as a result of the non-opposition (δι' ὁμαλότητα),
and *compression (σύνωσιν)* 62a6-b2

We interpret this difficult passage as follows:

There is a change from a Dispersion (at even stage 2n) waterlike dyad PW < PE, in which the primary water particles dominate the primary earth particles, and thus appear as small:

$$M_{2n-1}.PW < N_{2n-1}.PE < (M_{2n-1} + 1).PW$$

to a Consolidation (at next odd stage 2n + 1) earthlike dyad PW < PE, in which the primary water particles are dominated by the primary earth particles and thus appear great:

$$(N_{2n} - 1)\,.PE < M_{2n}.PW < N_{2n}.PE.$$

The primary water particles that appear great cannot enter and compress into the "hedrai"/ἕδρας of the primary water particles that appear small, but they enter and compress into the "hedrai" of the primary earth particles.

It is clear in passage 62a6-b2 that "hedrai" is used instead of "diakena." A mass of primary water enters and compresses a mass of primary earth in consolidation and presses out.

There are two more occurrences of "hedra,"

where [primary] air presses *(ὠθεῖ)* the adjacent body from its "hedra (*ἐκ τῆς ἕδρας,*79b4),
the body thus pressed (τὸ δ' ὠθούμενον) drives out in turn the next

and a situation of "antiperistasis" "εἰς *τὴν ἕδραν*" in 79b6, in the singular, but related to those above in the interchangeability with "diakena."

In all these passages, the smaller primary body enters into the "hedrai" (*in plural!*) of the greater primary body and "*sunothei*" (compresses) it. This is precisely the action of the smaller primary entity air described in 58a5, where, by the process of

tightening (ἡ τῆς πιλήσεως σύνοδος), the small (τὰ σμικρὰ) enter into the "diakena" (διάκενα) of the great (τῶν μεγάλων) and compress (συνωθεῖ) them (58b4-5; Sect. 10,1-2).

Furthermore, Simplicius' (*In Physics* 694,19-21) comment on the *Timaeus* 59a1-4 passage is revealing:

> and it is clear δῆλον that the "hedra" (ἕδρα) of [primary] fire was some chora (χώρα) in which the [primary] fire was. And that this is an area (διάστημα) of equal measure (ἰσόμετρον) in every body (τῷ ἐν αὐτῷ παντὶ σώματι). [Our rendering]

We have no choice, on the one hand, but to identify the "diakena" of the great with the "hedrai" of the great, and we also hardly have any choice but to identify *the "hedrai"* of the primary water, namely of the surface of the canonical *20hedron*, with the faces, the bases of the *20hedron.*

Note that it then makes perfect sense that the greatest primary bodies have the greatest empty spaces, as stated in 58a7-b6, something that scholars of *Timaeus* have difficulty explaining by misinterpreting, as they do, "diakena" as external empty space between particles of primary bodies, e.g., Cornford 1937, p. 245:

> But the coming-together involved in the condensing process (ἡ τῆς πιλήσεως σύνοδος) is always driving the smaller particles into the spaces left between the larger.

Section 10 ***The comprehension of the four primary bodies in the sphere, the geometric and that of the soul of the kosmos, has two fundamental consequences:***

(a) ***[Intelligence] The Third Kind participates in the Intelligible Being indirectly, by means of the Soul of Kosmos, thus forming a bastard intelligible (33a6-b5,* 36d8-e5, 52d2-4, 53a7-*b7, 53d6-7, 54a1-b1).***

(b) ***[Necessity] The dyad PE, PW, trapped in the sphere, and thus not able to generate anthyphairetic remainders and infinite kosmoi, is forced to use the participation in the intelligible for the generation of sensibles in Receptacle form leading to the One Kosmos (58a4-7).***

The Third Kind, consisting of the four primary bodies, has the power to generate all sensible bodies, as shown in Sect. 8, on the basis of passage 57d-58a. But two fundamental issues are still unresolved, leaving the whole endeavor in doubt.

One is that so far we have no argument in favor of the participation of the Third Kind in the intelligible, even a most confusing participation, as claimed in 51a7-b1, turning it into a "bastard" intelligible. This is *Plato's fundamental*, sine qua non *tenet:* Without participation of the sensibles in the intelligible, the intelligible loses its main "reason d' etre."

The second open issue is whether the type of sensibles that the Third Kind generates leads to the continued ad infinitum generation of anthyphairetic remainders and to the undesired infinite kosmoi, or to a Receptacle type sensibles, in terms of tight

double remainder-free inequalities, leading to the desired One Kosmos. The fact that we have switched from the intelligible cause to a geometric cause of sensibles does open the possibility for the desired second alternative but does not impose it, and as we saw in Sect. 8, the passage 57d-58a is neutral on this question.

It turns out that the answer to both problems, given in the short but fundamental passage 58a4-7, is based on the very special and unique property of the canonical solids, the *comprehension* of the canonical solids, and hence of the primary bodies, *in a sphere*, as shown by highly nontrivial proofs in the second half of Propositions 13–16 of the Theaetetean Book X of the *Elements*. It turns out that the setting of order, the *"kosmesis,"* of the World from its previous state of chaos and disorder coincides with the start of *participation* of the primary bodies in the intelligible by means of the Soul of the World.

10.1. *The participation of the Third Kind in the intelligible (51a7-b1, 52b1-2)*

Participation of the Sensibles in the Intelligible is absolutely necessary if we are to keep within Plato's philosophical system, in which the intelligible Beings dominate and govern the sensibles. Since the sensibles are generated by the Third Kind, it becomes absolutely necessary that the Third Kind *participates* in the intelligible, and that the participation of the sensibles to the intelligible will be assured exactly because of this participation of the Third Kind to the intelligible. On the other hand, such participation, turning the Third Kind into a "bastard" intelligible (52b1-2), will be difficult to explain, as Plato warns us in no uncertain terms in 51a7-b1, calling it "most difficult to conquer" (δυσαλωτότατον), since it will be a participation that no other geometric dyad shares, making the primary bodies unique among geometrical entities possessing such participation.

> we describe her as a Kind (εἶδός) invisible (ἀνόρατον) and unshaped (ἄμορφον), all-receptive (πανδεχές), and in some way most perplexing (ἀπορώτατά) and most difficult to conquer (δυσαλωτότατον) *partaking (μεταλαμβάνον) of the intelligible (νοητοῦ)* 51a7-b1

The statements in 53d6-7, asking whether the two triangles A and B and the sensibles originate from a higher principle (τὰς δ' ἔτι… ἀρχὰς ἄνωθεν), and in 54a2-b1 declaring that Triangle B forms, together with Triangle A, the most beautiful (τὸ κάλλιστον) geometric dyad, thus making them closest to the intelligible,[12] are preliminary toward the flat statement of participation.

10.2. *The setting of order ("kosmesis") of the World consists exactly in the institution of the* ***participation*** *of the Third Kind in the intelligible (51a7-b1, 52d2-4, 53a2-b7).*

[12] We know from *Sumposion* 211c8-d1, e1, that *every* intelligible true Being, and not just the Idea of the Beautiful, is a most beautiful entity; it is beauty itself. This is the method that Plato describes by means of which the idea of the beauty is most beautiful, in short "ephexes" and "exaiphnes," and is exactly the method of (anthyphairetic) Division and Collection (Logos Criterion), respectively, that holds for every intelligible Being.

There was a time that the World was not yet set in order. The intelligible Beings, the sensible bodies, and the Receptacle, and even the *separation* into four different *places* for the four primary bodies, existed *before* order "kosmesis" was set in the World:

> Let this, then, be, according to my verdict, a reasoned account of the matter summarily stated,—that Being (**ὄν**) and Place (χώραν) and Generation (**γένεσιν**) were existing, three distinct things, *even before the Heaven (οὐρανὸν) came into existence* 52d2-4

> wherefore also these [four Kinds] [τὰ τέτταρα γένη]
> occupied different places (διὸ δὴ καὶ χώραν ταῦτα ἄλλα ἄλλην ἴσχειν),
> even before that the Universe (*πρὶν* καὶ τὸ πᾶν) was *set in order (διακοσμηθὲν)*
> and *generated out of them* (ἐξ αὐτῶν γενσθαι).
> *Before that time* (τὸ μὲν δὴ *πρὸ τούτου*), in truth, all these things were in a state
> without "logos" or measure (ἀλόγως καὶ ἀμέτρως) 53a2-8

It is clear that *if* the sensibles *participate* in the intelligible, then the sensibles *cannot* be in a state without logos and measure, without the presence of God. It is clear from this description that before order was set there could be *no participation* of the World and of the Receptacle in the intelligible.

> but when the work of setting in order this World (κοσμεῖσθαι τὸ πᾶν) was being undertaken, fire and water and earth and air, although possessing some traces of their own nature, were yet so disposed as everything is imaged (εἰκὸς) in the absence of God; and inasmuch as this was then their natural condition, God began by first *marking them out into shapes (διεσχηματίσατο) by means of forms and numbers (ε δεσί τε καὶ ἀριθμοῖς)*. And that God constructed them, so far as He could, to be as *fair (κάλλιστα) and good (ἄριστά)* as possible, whereas *they* had been otherwise (*ἐξ οὐχ οὕτως ἐχόντων*) —this above all else must always be postulated in our account. 53b1-7

Again it is clear that when order was instituted in the World, then the sensibles were shaped by kinds and numbers, namely by intelligible materials, something that would be impossible without participation of the sensibles in the intelligibles. So the time when order of the kosmos was instituted must be *exactly* the time when the sensible bodies started to participate in the intelligible. What did not exist then, before "kosmesis," was *participation* of the sensible bodies in the intelligible.

We have shown already (a) that the sensible bodies are generated from the primary bodies, and also (b) that the Third Kind has been identified with the four primary bodies. Plato expressly states (10.1) that the Third Kind participates in the intelligible; on the other hand, a priori there is no reason to believe that the geometrical primary bodies *qua* geometrical bodies participate in the intelligible, and indeed Plato prepares us for a mode of participation most unusual and far from obvious. It follows that we are urgently in need of an indication that the Third Kind, namely the primary bodies, participates in the intelligible.

10.3. *The participation of the Soul of the World in the intelligible dyad <IE, IF> (33a6-b5, 36d8-e5)*

The World is spherical (σφαιροειδές) and circle-like (κυκλοτερὲς, 33b5, same as in 58a5), *because* it is constructed in similarity to, in imitation of the paradigm, the *intelligible Being* with dyad <IE,IF> (*Timaeus* 33a6-b5), which has *periodic* anthyphairesis;

the periodic motion, the revolution of the World, is due to its Soul and is controlled and powered by the intelligible periodic anthyphairesis (*Timaeus* 36d8-e5). It is clear that periodicity is the property that makes the World *ageless* (ἀγήρων, as in *Politicus* 273e4, *Philebus*, 15d8).

10.4. *The comprehension of the primary bodies in the spherical Soul of the Kosmos results in the "δυσαλωτότατον" participation of the Third Kind, the secondary, bastard cause,* via *the spherical Soul of the World, in the Intelligible, the real, and ultimate cause and in sensibles is described by double tight remainder-free inequalities, ensuring the One Kosmos (58a4-7).*

We now come to the brief but fundamental passage 58a4-7.

> The revolution of the World (ἡ τοῦ παντὸς περίοδος),
> [1] since it comprehended (συμπεριέλαβεν) the [primary] Kinds (τὰ γένη),
> [2] seeing that it is circle-like (κυκλοτερὴς) and
> wishing (βούλεσθαι) naturally (πεφυκυῖα) to come together (συνιέναι) to itself (πρὸς αὑτὴν),
> [3] tightens (σφίγγει) everything (πάντα) and thus it allows not even one part (οὐδεμίαν) of empty place (κενὴν χώραν) to be left (ἐᾷ λείπεσθαι). 58a4-7

[1]. This is the only passage that connects the four primary bodies (τὰ γένη), and thus the Third Kind, with the Revolution of the World, and thus establishes the participation of the Third Kind in the intelligible. The key sentence is "since [the revolution of the World] *comprehended* (συμπεριέλαβεν) the primary bodies."

What does this mean exactly?

The first thing to realize is that the word "*comprehended/συμπεριέλαβεν*" that Plato is using in 58a4-7 essentially coincides with the word "*comprehend/περιλαβεῖν*" used in the Theaetetean Book XIII of Euclid's *Elements,* where in Propositions XIII.13–16 it is shown, with great effort, that each of these regular solids can be comprehended in the sphere (σφαίρᾳ περιλαβεῖν). It is clear that Plato is using here Theaetetus' mathematical Propositions and terminology.

We distinguish two consequences of this comprehension.

The first is that *the real and ultimate cause* of the sensibles, namely the anthyphairetically periodic *intelligible Being*, is able to transmit its intelligible anthyphairetic power of motion, by means of the intermediary, namely the sphericity of the World Soul (κυκλοτερὴς, 33b5, 58a5),

to the *Third Kind*,

namely to the incommensurable dyad PE, PW, aided by the auxiliary commensurable dyads PW/PA = 5/2 and PW/PF = 5/1,

exactly because the constituents of the Third Kind, the primary bodies, are *comprehended* in the intermediary sphere and revolve with it;

as a result, the Third Kind is provided with power of motion and generation of the sensibles and becomes a *secondary cause* for the sensibles, as described on the basis of 57d-58a, in Sect. 8.

[2]. But we are next told that the motion of the Soul of the Kosmos is cyclical, periodic, tending to return to itself. Yes indeed, this is characteristic of every circular, periodic motion, and so it applies to the motion of the Soul of the Kosmos. But what is new or interesting?

[3]. Well, as a consequence the revolution of the Soul of the World

> tightens (σφίγγει) everything (πάντα) [the primary bodies]
> and thus it allows not even one part (οὐδεμίαν) of empty place (κενὴν χώραν)
> to be left (ἐᾷ λείπεσθαι).

We believe this consequence, essential for Plato, has not been understood properly by scholars thus far. We attempt to enlighten it. An explanation that tries to explain this situation of "tightening," "compressing," and "not leaving even one empty space" mechanically, solely by means of the nature of the circular motion in general, has no chance of success.

Here we are dealing with the Third Kind, consisting of the incommensurable dyad PE, PW (plus the two auxiliary ones), already having assumed, by passage 57d-58a, the role of the cause of the sensibles, substituting in that role the intelligible. Thus, the dyad PE, PW generates initial segments of its infinite anthyphairesis.

Now it is crucial to see what form will these products assume. A priori the dyad could generate either anthyphairetic remainders or double tight remainder-free inequalities. As we have already noted (Sect. 8), passage 57d-58a does not take sides on this issue. The evidence presented in Sect. 9 in favor of the second alternative (remainder-free inequalities, leading to the elimination of infinite kosmoi) does not offer a reason for this choice.

This reason is offered precisely now with 58a4-7. Indeed, the primary bodies are caged, trapped *within the confines of the One spherical World/Kosmos,* and hence cannot employ the power of motion granted them by the intelligible to generate new, potentially infinitely many anthyphairetic remainders and hence potentially infinitely many kosmoi. Thus the primary bodies have no other choice and *are forced by necessity* to turn the transmitted intelligible power of motion internally, according to the mathematics of generalized side and diameter numbers, tight, double remainder-free inequalities, toward one kosmos. Thus we have finally the answer to the question why all generations of sensibles examined (in Sect. 9) were always toward preserving the one kosmos.

This reasoning is lost among scholars because they do not realize that what the Third Kind is set to accomplish is the elimination of infinite kosmoi.

This is a very important passage, because it seems to be the only one that connects the four primary bodies, and their *geometric* infinite, in fact periodic, anthyphairesis of the triangles A and B, with the *intelligible, by means* of the period of the soul of the *world*. At the same time, the primary bodies are the only geometric entities that are endowed with participation in the intelligible by means of the World Soul.

This turns the Third Kind, on the one hand, *purely geometric downward* as it generates the sensible bodies as syllables of the form Content & Receptacle, and

on the other hand, it keeps contact with the intelligible through the soul of the World and substitutes for the intelligible as the cause of the sensibles, thus in fact a *"bastard intelligible" upward.*

10.5. *The kosmos is a mixture of intelligence and necessity*

Now we are ready to make sense of the passage 47e-48a and of the exact meaning of necessity in relation to kosmos and the Sensibles:

> The foregoing part of our discourse, save for a small portion, has been an exposition of the operations of *Intelligence* (διὰ νοῦ, rendered by Lamb Reason); but we must also furnish an account of what comes into existence through *Necessity* (δι' ἀνάγκης). For, in truth, this Cosmos in its origin was generated as a compound (μεμειγμένη), from the combination of Necessity and Intelligence.
> And inasmuch as Intelligence was *controlling* Necessity by persuading (τῷ πείθειν) her to conduct to the best end the most part of the things coming into existence, thus and thereby it came about, through Necessity yielding (ἡττωμένης) to intelligent persuasion (πειθοῦς ἔμφρονος), that this Universe of ours was being in this wise constructed at the beginning.
> Wherefore if one is to declare how it actually came into being on this wise, he must include also the form of *the Errant (or Wandering) Cause* (τὸ τῆς πλανωμένης εἶδος αἰτίας), and how it is in its nature to cause movement and change (φέρειν πέφυκεν). 47e3-48a7
> [translation by WRM Lamb, modified by the authors]

"Nous" is rendered by most translators (Lamb, Cornford, and Waterfield) as Reason, but what is meant is precisely intelligence. Thus, kosmos is a mixture of intelligence and necessity.

The role of intelligence in the kosmos is well-defined: It is precisely the participation of the sensibles in the Intelligible (10.1-3).

Since the Receptacle/Chora is considered *necessary* (*εἰσαναγκάζειν*, 49a3; *ἀναγκαῖον ε ναί*, 52b3-5) for the adequate description of kosmos, it is clear that necessity is related to the Receptacle. But the Receptacle, the Third Kind, as we have seen, was necessary to be introduced solely for ensuring that there is only one kosmos with four kinds while, on the other hand, as we have seen in Sect. 3, the oneness of kosmos is NOT a consequence of its participation in the intelligible; the intelligible is neutral and makes it equally possible for one kosmos or for infinitely many kosmoi.

The One Kosmos has been imposed essentially by the nondialectical choice of introducing the Third Kind in terms of the primary bodies. The fundamental fact that

imposed One Kosmos was *the comprehension of the primary bodies, the constituents of the Third Kind, in a sphere*.

Thus, the primary bodies, and specifically the dyad <PE, PW>, on the one hand, because of its participation to the intelligible, are endowed with the valuable transmitted knowledge of how to generate sensibles and, on the other hand, are trapped, caged, and confined in the cosmical sphere, and thus unable to generate infinite remainders and infinite kosmoi, since these remainders would have to go, as lighter above and beyond the sphere (as explained in Sect. 3); they are forced then by *sheer necessity* to turn to the only other possible manner of generating sensibles, that of Receptacle and tight Inequalities, thus staying within the confines of one kosmos.

Thus, the kosmos is indeed a mixture of intelligence and necessity, with intelligence in control of necessity, by means of True Opinion.

11. *The nature and the structure of the sensible bodies in the Timaeus: The sensibles participate in the intelligible* via *the Third Kind; every sensible is a syllable of the form Receptacle & Content; and there are four kinds of sensibles in one kosmos*

We are now, at long last, able to describe fully the nature and the structure of the *Timaeus* sensibles.

Every sensible body contains the dyad
a mass N.PE as Receptacle, and a mass M.PW as Content,
thus forming the sensible

$$\text{M.PW} < \text{N.PE}$$

either in Dispersion or in Consolidation.
To this dyad M.PW < N.PE as Receptacle,
a mass K.PA or a mass K.PF may be added as auxiliary Content,
thus forming the sensible

$$\text{K.PA} < (\text{M.PW} < \text{N.PE}) \text{ or } \text{K.PF} < (\text{M.PW} < \text{N.PE}),$$

either in Dispersion or in Consolidation. These are essentially the only possible sensible bodies. The complete list of sensibles is given in Sect. 11.2 below.

We conclude that the sensibles *participate in the intelligible* via *the Third Kind, and* are syllables of the form Content & Receptacle, four kinds of them in one kosmos.

11.1. *The sensible bodies as the class of entities whose* ***cause*** *is the primary dyad PE, PW*

It will turn out that every sensible body is a syllable with basic dyad PW < PE.

(a) *The dyad PE, PW is* ***the cause*** *of the generation and motion of the earthlike and waterlike sensibles.*

This is precisely the content of Sects. 9.1 and 9.2.

(b) *The dyad PE, PW is* ***the cause*** *of the generation and motion of the airlike and firelike sensibles, as well.*

But the class of earthlike and waterlike sensibles does not exhaust all sensibles.

The fact that Plato has rejected the possibility of direct interaction of PE with either PA or PF does not mean that there is no interaction between these primary bodies.

How can sensible air be generated?

We will need a *syllable* that contains primary air PA.

Can the dyad $\boxed{\text{PA}} \leq \text{PW}$, presumably in Dispersion, meaning

$\text{K.PA} \leq \text{L.PW} < (\text{K} + 1).\text{PA}$ for some numbers K, L, be such a syllable? Such a dyad *by itself* is certainly rejected as a possible sensible air, exactly because this dyad has *no cause* for generation or motion (or equivalently, it *does not participate* in a periodic anthyphairesis of the primary bodies, since the dyad PW, PA is commensurable with finite anthyphairesis).

Since a direct interaction between PE and PA has been excluded (Sects. 8.4 and Sect. 10), it is clear that the only possibility is to *form*

the triad $\text{PA} \leq (\text{PW} < \text{PE})$,

symbolizing that

the particles of the primary water PW enter and fill fully, not leaving even one empty space, into the "diakena" of the primary earth PE, and

the particles of the primary air PA enter and fill quite fully into the already existing "diakena" of the water PW;

furthermore, in order that the triad in question is *sensible air,* the two dyads $\text{PW} < \text{PE}$ and $\text{PA} \leq \text{PW}$ must be in Dispersion, symbolically

$\boxed{\text{PA}} \leq \left(\boxed{\text{PW}} < \text{PE}\right)$.

Thus, the interaction of PA or PF with PE does materialize but in an *indirect* way, namely as a triad $\text{PA} \leq \text{PW} < \text{PE}$, *defined* as the composition of

the principal incommensurable interaction dyad $\boxed{\text{PW}} < \text{PE}$, meaning, as we have said, that there are natural numbers M, N, such that $\text{M.PW} < \text{N.PE} < (\text{M} + 1).\text{PW}$,

followed by the auxiliary commensurable perturbation

dyad $\boxed{\text{PA}} \leq \text{PW}$,

meaning that there is a natural number K, such that $\text{K.PA} \leq \text{M.PW} < (\text{K} + 1).\text{PA}$,

or dyad $\boxed{\text{PF}} \leq \text{PW}$,

meaning that there is a natural number K, such that $\text{K.PF} \leq \text{M.PW} < (\text{K} + 1).\text{PF}$.

Let us make sure that the primary dyad PE, PW deserves to be considered *the cause* not only for every sensible dyad $\text{PW} < \text{PE}$,

but also for all triads $\text{PA} \leq \text{PW} < \text{PE}$, or $\text{PF} \leq \text{PW} < \text{PE}$.

Assume, e.g., $\boxed{\text{PA}} \leq \left(\boxed{\text{PW}} < \text{PE}\right)$.

Since $\boxed{\text{PW}} \leq \text{PE}$ is in Dispersion, there are natural numbers M, N, such that $\text{M.PW} < \text{N.PE} < (\text{M} + 1).\text{PW}$.

Since $\boxed{\text{PA}} \leq \text{PW}$ is in Dispersion, there is a natural number K, such that
$\text{K.PA} \leq \text{M.PW} < (\text{K} + 1).\text{PA}$.
But since *PW/PA = 5/2*, it is immediate that
K is just the integer part of the rational (5/2).M.
Thus, K is determined by the number M, itself determined by the cause PE, PW!
Thus, we can say that the triad $\boxed{\text{PA}} \leq (\boxed{\text{PW}} < \text{PE})$ is caused by the dyad PE, PW.
Thus, sensible air is by necessity a triad, a syllable with three primary elements/letters,
and similarly a sensible fire is a triad $\text{PF} \leq \text{PW} < \text{PE}$, as described in 60e-61a
(or possibly even a tetrad $\text{PF} \leq \text{PA} \leq \text{PW} < \text{PE}$, although Plato does not appear to mention any such example).

Examples (58d8-e3, 61a2-4)
Passage 58d8-e3 describes the most violent change from earthlike sensible to firelike.

> But the other kind, which is composed of great and *unopposed* (ὁμαλῶν) particles,
> is more stable than the first and is heavy,
> being solidified by its state of *non-opposition* (ὑπὸ *ὁμαλότητός*) 58d8-e2

The initial state is clearly the fundamental sensible dyad in consolidation, generating an earthlike sensible dyad: $(\text{N}_{2n} - 1).\text{PE} < \text{M}_{2n}.\text{PW} < \text{N}_{2n}.\text{PE}$; thus, $\text{PW} < \boxed{\text{PE}}$.

> but when fire enters (ὑπὸ δὲ *πυρὸς* εἰσιόντος, 58e2) and dissolves it,
> this causes it to abandon its state of *non-opposition (ὁμαλότητα*, 58e3)

Fire enters into the diakena of water, and finite Dispersion takes place between PW and PF, symbolically $\boxed{\text{PF}} \leq \text{PW}$. This Dispersion unbalances the internal situation in the initial dyad PE and PW, and, by going to the next step in the infinite anthyphairesis, a change occurs *from Consolidation* $\text{PW} < \boxed{\text{PE}}$ *to Dispersion* $\boxed{\text{PW}} < \text{PE}$ by going to the next stage of the anthyphairesis of PE to PW:
$\text{M}_{2n+1}.\text{PW} < \text{N}_{2n+1}.\text{PE} < \text{M}_{2n+1}.\text{PW}$.
There results the following firelike sensible triad: $\boxed{\text{PF}} \leq (\boxed{\text{PW}} < \text{PE})$, a *firelike* sensible body: $\text{K}_{2n+1}\text{PF} \leq \text{M}_{2n+1}.\text{PW} < (\text{K}_{2n+1} + 1)\text{PF}$. Since $\text{PW/PF} = 1/5$, K_{2n+1} is immediately seen to be equal to $\text{M}_{2n+1}.\text{PW/PF} = 5$. M_{2n+1}, determined by M_{2n+1}.
A similar situation is described in passage 61a2-4:

> If mixed [primary Earth] (*συνεστηκυῖαν* δὲ [[γῆν]]) [with primary water] is generated
> only [primary] fire (πλὴν πυρὸς οὐδέν) can disperse it,
> for no entrance (εἴσοδος) is left (λέλειπται) for anything but fire *(οὐδενὶ πλὴν πυρὶ)*. 61a2-3

Mixed *(συνεστηκυῖαν)* primary earth necessarily means that primary earth is mixed with primary water, the only possible mixture for primary earth, in the sense that masses of primary water enter into the "diakena" of primary earth, and consolidation takes place generating an earthlike sensible body, namely the dyad PW < $\boxed{\text{PE}}$. Only primary fire *(πλὴν πυρὸς οὐδέν)* can disperse this earthlike sensible body, as follows: Primary fire PF enters and fills the diakena of primary water PW, in Dispersion $\boxed{\text{PF}}$ < PW; this Dispersion forces the infinite anthyphairesis of PE to PW to go to the next stage, *from Consolidation* PW < $\boxed{\text{PE}}$ *to Dispersion* $\boxed{\text{PW}}$ < PE, and generating a sensible firelike triad ($\boxed{\text{PF}}$ < ($\boxed{\text{PW}}$ < PE).

Primary air PA is presumably too weak for such a drastic action, which is the prerogative of PF.

> *[primary] water* when most forcibly mixed (βιαιοτάτην ὕδατος σύνοδον) *[with primary earth]* is dispersed *by [primary] fire only* (*πῦρ μόνον* [διαχεῖτον]) 61a3-4

Primary water *mixed* with primary earth is PW < PE; primary water *most forcibly* mixed with primary earth can only mean that PE is victorious, namely PW < $\boxed{\text{PE}}$, thus forming an earthlike sensible body, a "chuton." Only primary fire (πῦρ μόνον) can disperse this sensible body, changing as above *from internal Consolidation to Dispersion* by proceeding one step in the infinite anthyphairetic division, and thus forming the sensible *firelike* triad $\boxed{\text{PF}}$ < ($\boxed{\text{PW}}$ < PE) (61a3-4).

Thus the case "συνεστηκυῖαν [γῆν]" in 61a2-3 coincides with the case "βιαιοτάτην. . . ὕδατος σύνοδον" in 61a3-4.

11.2. *The sensible bodies are **not elements** and principles, but at least syllables (48b3-c2)*

This passage points out that the traditional four elements theory of sensibles will be modified by Plato, so that there are indeed four kinds of bodies but they are not elements *but at least syllables*, with elements other entities more basic and elemental.

> We must gain a view of the real nature of fire and water, air and earth,
> as it was before the generation of Heaven (πρὸ τῆς οὐρανοῦ γενέσεως),
> and the properties they had *before that time* (καὶ *τὰ πρὸ τούτου πάθη*);
> for *at present* (*νῦν* γὰρ) no one has as yet declared their generation (**γένεσιν**),
> but we assume that men know what fire is, and each of these entities,
> and we call them *principles (ἀρχὰς)* and
> presume that they are *elements (στοιχεῖα)* of the Universe,
> although in truth they do not so much as deserve to be likened (ἀπεικασθῆναι)
> with any likelihood, by the man who has a grain of sense,
> to the class of *syllables only* (ἐν συλλαβῆς εἴδεσιν *μόνον*) 48b3-c2

Indeed, according to Sect. 11.1, every sensible has one of the following forms:

Sensible bodies			
Earthlike	Waterlike	Airlike	Firelike
PW < [PE]			
	[PW] < PE		
PA < (PW < [PE])			
	PA < ([PW] < PE)		
		[PA] < ([PW] < PE)	
PF < (PW < [PE])			
			[PF] < ([PW] < PE)

It is thus understood in what sense every sensible body must be "at least a *syllable.*"

It follows that a primary body by itself cannot be a sensible body, as believed by most scholars. Let us make sure what dyads or even long "syllables"[13] consisting of the same primary body *cannot* constitute a sensible body.

Every sensible entity
either consists of the dyad PW < PE, in Consolidation or in Dispersion,
or of the dyad PW < PE extended by PA or PF.
For every sensible body, the ultimate Receptacle is primary Earth.

11.3. *The participation of the Third Kind in the intelligible and the incommensurability of the primary earth to primary water cause incessant motion and change of the sensibles into each other.*

We are finally in a position to explain why in Plato's model the motion of the world is incessant.

> but we have not declared
> how it is that it is *not* the case (*πῶς δέ ποτε οὐ*) that
> these [primary] bodies are separated according to their several Kinds (κατὰ γένη διαχωρισθέντα), and cease from their motion and passage one through another
> (*πέπαυται* τῆς δι' ἀλλήλων κινήσεως καὶ φορᾶς)
> Wherefore, we shall once more expound the matter as follows. 58a2-4

Plato has managed to deal with the "infinite kosmoi" infinity, and the result is a One Kosmos, with four Kinds theory, participating in the intelligible. But it should not be thought that infinity has disappeared altogether from Plato's dialectics on Sensibles. The potential infinity of the collection of sensibles is still present, but in a

[13] Plato speaks of syllables in various instances. Typical syllables he mentions are ΣΩ (*Theaetetus* 203a8), ΘΕ, ΤΕ (207e8-208a1); certainly, he would never regard something like ΘΘΘΘΘ, and so on, as a syllable.

different manner. In fact, it manifests itself in a "positive" manner, by guaranteeing incessant, *infinite motion* of "kosmos."

[1]. Let us imagine for the moment that all primary bodies were placed in their natural places/regions, with no interaction between them.
[2]. Before the "kosmesis" and the participation to the intelligible, there would be no reason for the primary bodies to move so as to come close to each other and to interact, and in fact this is the basic difference of the universe before "kosmesis" and after. With "kosmesis" and participation of the Third Kind in the intelligible, the primary bodies do not stay for long by themselves; they try to fill their empty "diakena"/"hedrai"/faces, and generate sensibles.

This may be thought of as the will (βούλεσθαι) of "kosmos," whose Soul is like a living creature, whose purpose is to become as similar as possible to the intelligible paradigm. This means that the soul of the kosmos will "compress" and "tighten" to proceed as far as possible in the stages of anthyphairesis, and obtain a better approximation of the paradigm. But the number of available particles of, say, primary water and of primary earth is in any particular case finite, hence the process of approximation and convergence will necessarily stop at some finite stage, exactly because the number of such parts is finite. Thus, the result will be an imperfect sensible approximation of the intelligible (Cf. 10.1, 10.2).

[3]. In both cases, *motion* to the place/region of the victorious results upward in Dispersion, downward in consolidation (Cf. 10.3, 10.4, 10.5).
[4]. Whatever is generated, namely a sensible, might be transformed into another sensible but will eventually be corrupted, because it is not perfect, but a highly imperfect approximation of something perfect but infinite. The world, pressed by the intelligible, strives for something better. Thus, every sensible body is eventually corrupted, dismantled, and the constituting materials, the primary bodies, go to their own places/regions. Thus, we return to stage [1].

> And since in this way and for these reasons
> the generation (γένεσις) of irregularity (τῆς ἀνωμαλότητος)
> is perpetually *(ἀεὶ)* maintained *(διασῳζομένη),*
> it brings about unceasingly, both now and for the future,
> the perpetual *(ἀεὶ) motion (κίνησιν)* of these bodies. 58c2-4

Infinite motion of the "kosmos" is an eventual consequence both of the built-in anthyphairetic infinity, the same built-in infinity that caused the problem of "infinite kosmoi," and of the participation of the Third Kind in the intelligible.

Cornford's 1937, p. 245, interpretation, finding only mechanical causes, and not connecting the infinity of motion with the infinity of incommensurability, and eventually with the participation to the intelligible, is far from adequate.

11.4. *Sensibles differentiated from the intelligible*

11.4.1. *The difference between*
a sensible dyad
(*by assimilation,* ***simultaneously both one and two*** *(52c7-d1), a* ***confounded dyad*** *(Politeia 524c3-9)) and*
an intelligible dyad
(by equalization, separate with ***equalized units*** *(Politeia 524b10-c1))*

The equalization of the two parts of the dyad, in an intelligible Being, has been described in the second hypothesis of the *Parmenides* and analyzed in Negrepontis TA. Thus, the unequal parts One, Being, since part One is greater than part Being, are nevertheless *equalized* by the condition:

the *number* of parts of the One is finite and equal to the *number* of parts of the Being
Parmenides 144e1-3,

a consequence of the philosophical analogue of the Logos Criterion and the anthyphairetic periodicity of the intelligible Being. The same criterion obtains for every intelligible Being, for example, the Being and not-Being in the *Sophistes*, and also for every geometric periodic anthyphairesis. Intelligible equalization is an equivalence, thus symmetric, relation. This equalization of the two parts allows for the platonic definition of the intelligible number Two.

> If, then, each is one (ἐν ἑκάτερον) and both two (ἀμφότερα δὲ δύο),
> the very meaning of 'two' is that
> the soul (νοήσει) will conceive them as separate (κεχωρισμένα) *Politeia* 524b10-c1

By contrast, the sensible two does not consist of parts each of which separately is a unit equal to the other. The description of the sensible dyad as confounded, but not separated as the intelligible, in the *Politeia* 524c is not entirely understandable by what is said in the *Politeia*.

> Sight (ὄψις) too saw (ἑώρα) the great and the small *(Μέγα. . .καὶ σμικρὸν)*, we say,
> not separated (οὐ κεχωρισμένον) but confounded (ἀλλὰ *συγκεχυμένον*). *Politeia* 524c3-5

Plato clarifies this difference as follows:

> *the intelligence* is compelled to contemplate *the great and small*,
> *not thus confounded (οὐ συγκεχυμένα) but as distinct entities (ἀλλὰ διωρισμένα)*,
> in the opposite way from *sensation*. *Politeia* 524c6-9

But it becomes quite clear when completed with the *Timaeus* 52c7-d1 description as "simultaneously both one and two."

One of the two parts of the sensible dyad PW < PE, the Content, is a mass of primary water, and the Receptacle is a mass of primary earth; one of them is the active/victorious, the other the passive/defeated, the passive becomes approximately similar to the active, and the whole dyad becomes active-like (*Timaeus* 51e6-52a4, 52c5-d1). There is thus no equalization in the *sensible,* of the Receptacle & Content parts; the initial opposition results in a fight, a battle, and there is a victorious and a defeated part, the defeated assuming, in an approximate way, the form of the victorious. Here the assimilation is NOT symmetrical, only approximate (Sect. 10.4).

whereas to the aid of the intelligible Being (τῷ δὲ ὄντως ὄντι)
there comes the accurately true logos (ἀληθὴς λόγος), that so long as
one thing will be *generated in the other thing* (οὐδέτερον *ἐν οὐδετέρῳ γενόμενον*)
so that they *become* (γενήσεσθον) *the same thing (ταὐτὸν)*
simultaneously *(ἅμα) both one and two (ἓν καὶ δύο). Timaeus* 52c5-d1

Finally, according to 52c5-d1, the dyad of the intelligible Being does not admit a description of the form Content & Receptacle, with a mass of Content particles inside a mass of Receptacle particles; this passage is more informative than 51e6-52a4, in that it is the intelligible Logos of periodicity and equalization (hinted in the 51c-52a passage by the reference to the self-identical kind) that obstructs the generation of one part in another. The *intelligible* equalization is a consequence of the Logos Criterion of anthyphairetic periodicity, while the *sensible* assimilation is a consequence, in the absence of the Logos and periodicity, of a far weaker condition of only an initial finite approximation of the infinite anthyphairesis, in the form of Receptacle & Content.

11.4.2. *A sensible body participating in intelligible F is sometimes F, sometimes not F (Sumposion 210e-211a, Politeia 479a-b)*

This is a persistent and prominent pre-*Timaeus* feature of the sensibles (*Sumposion* 210e-211, *Politeia* 475e-480a); the latter passage was described in Sect. 2.2. It is clear that Plato regards it as fundamental, but students of Plato have never explained it in a satisfactory manner. With our present analysis of the structure of the sensibles bodies, this property becomes transparent.

For example, the same sensible pair PW < PE is

sometimes heavy, at every even stage of the anthyphairesis, namely when the dyad Receptacle & Content is in *consolidation***,** and then is a *sensible earthlike*, PW < $\boxed{\text{PE}}$, and

sometimes light, at every odd stage of the anthyphairesis, namely when the dyad Receptacle & Content is in *Dispersion*, and then is a *sensible waterlike*, $\boxed{\text{PW}}$ < PE. It is thus clear that the origin and nature of this property is anthyphairetic.

An excellent example of PW < PE is the generation of flesh (74c5-d2), in Dispersion, not E, and the generation of bone (73e1-5), in consolidation, E.

11.5 *Sensibles differentiated from the Third Kind:*

Only the ***nonsensible, geometrical*** *triangles A and B and the primary bodies that are the elements of the Receptacle-Content inequalities can be called* ***"this,"***

while a ***sensible body****, represented by the Receptacle-Content inequalities, must be called* ***only "such" and not "this"*** *(Timaeus 49d4-50a2).*

> Whatsoever object we perceive to be constantly changing from one state to another (ἄλλοτε ἄλλῃ γιγνόμενον), like [sensible] fire, that object, be it [sensible] fire,
> we must never describe as "this" but as "suchlike," (μὴ τοῦτο ἀλλὰ τὸ τοιοῦτον ἑκάστοτε προσαγορεύειν πῦρ) nor should we ever call [sensible] water "this" but "suchlike" (μηδὲ ὕδωρ τοῦτο ἀλλὰ τὸ τοιοῦτον ἀεί),
> nor should we describe any other element, as though it possessed stability (βεβαιότητα), of all those which we indicate by using the terms "this" and "that" (τῷ τόδε καὶ τοῦτο) and suppose ourselves to refer to a definite object.
> For such an object shuns (φεύγει) and eludes (οὐχ ὑπομένον) the names "this" and "that" (τὴν τοῦ τόδε καὶ τοῦτο καὶ τὴν τῷδε) and every name which indicates that they are stable (μόνιμα). Thus we must not call the several elements "these,"
> but in regard to each of them and all together
> we must apply the term "suchlike" (τοιοῦτον) to represent what is always circling round: thus we shall call that which is constantly "suchlike" (τοιοῦτον) by the name of fire,
> and so with everything else that is generated (ἅπαν ὅσονπερ ἂν ἔχῃ γένεσιν). 49d4-e7
> But that "wherein" (ἐνᾧ) they are always, in appearance, coming severally into existence,
> and "wherefrom" (ἐκεῖθεν) in turn they perish,
> in describing that and that alone should we employ the terms "this" and "that"
> (μόνον ἐκεῖνο αὖ προσαγορεύειν τῷ τε τοῦτο καὶ τῷ τόδε προσχρωμένους ὀνόματι)
> 49e7-50a2

According to the "much mis-read" passage

- the sensible entities, namely the entities generated by Dispersion and consolidation, the syllables of primary bodies, seen as fire, air, water, earth, should be always called
  "such" and not "this,"
- while the elements of the receptacle, the primary bodies, and their surfaces should be called "this" and not "such."

H. Cherniss attempted to interpret this passage thus:

> '*ἀεὶ* περιφερόμενον ὅμοιον' here must have the same meaning:
> "always recurring alike," i. e. "always self-identical in its recurrences."
> Cherniss 1954, p. 121

But in fact Plato has explained elsewhere when an entity is called "such":

> 'being *such* (ὁ τοιοῦτοςὢν) he will be *like* **to** *such* (καὶ ἐοικέναι τοῖς τοιούτοις)'
> 'Then each is *such* (τοιοῦτος ἄρα ἐστὶν) as that to which he is *like* (οἷσπερ ἔοικεν.)'
> *Politeia* 349d8-10
> 'as that to which he is *similar* (ᾧγε ὅμοιος ἑκάτερος εἴη), *such* is each (τοιοῦτον καὶ ἑκάτερον εἶναι.)' 350c7-9

As we have seen, the generation of a sensible by dispersion (diakrisis) or consolidation (sugkrisis) makes the sensible to be dissimilar to itself and *similar to others*. Cf. Sections 9.1 and 9.2. So it is *by being similar to others* that a sensible becomes "*such*," contrary to Cherniss' interpretation. If "such" were going to be a fitting name to something that always stays *similar to itself*, then the receptacle, even the intelligible, would be the perfect entity to be called "such." But the receptacle is called "this" and not "such," precisely, because it is not assimilated to something different.

Thus, Cherniss is right in that "such" must refer to some likeness, but is mistaken to believe that it is *self-similarity*, and not *becoming similar to the others*; his explanation is thus totally off the mark.

Theaetetus 201c-202c passage bears some verbal resemblance to the *Timaeus* 49d-50a passage. But there, the differentiation is between

"name only," namely anthyphairetic division only, true opinion/sensible, and

"name and logos," division and Logos criterion of periodicity, intelligible.

Section 12 ***Additional comments on earlier interpretations of the Receptacle***

[1]. Scholars have described the Receptacle as difficult to understand and perhaps self-contradictory, e.g.,

> "The account that Plato gives of the Receptacle itself is at best obscure (as he admits, 49a3-4) and at worst incoherent." Zeyl 2000, p. lxi
> "The receptacle is probably the hardest and most philosophically challenging concept in *Timaeus*." A. Gregory, R. Waterfield, 2008, p. xlix

But in fact, as we have seen, the Receptacle makes perfect sense as a vivid and imaginative description of the double tight remainder-free anthyphairetic inequalities.

[2]. Scholars either ignore or undermine the fundamental "infinite kosmoi" question and problem as simply a puzzling peripheral problem (Cornford 1935; Gregory 2001) or suggest rather exotic interpretations (Rashed 2013).

> This passage [55c] is extremely puzzling. There is nothing in the previous context to suggest a plurality of worlds; p. 221
> the ancients, who seem to have found the passage as obscure as it is to us
> Cornford 1937, p. 220

But, as we saw in Sect. 3, Plutarch had a quite good notion of the problem of infinite kosmoi, besetting Plato's pre-*Timaeus* theory of sensibles.

> The passage at Timaeus 55c has long been considered a rather puzzling one.
> Gregory 2001, pp. 42–43

Both Cornford and Gregory express puzzlement that Plato returns to the question at 55c, right before identifying the primary bodies with the corresponding canonical solids. But, as we have shown, the problem of infinite kosmoi is the sole problem that

necessitated the introduction of the Receptacle. Treating the problem of infinite kosmoi as peripheral makes it impossible to explain the necessity in introducing the Third Kind.

[3]. Most scholars (including Cornford 1937; Algra 1995; Zeyl 2000; Gregory 2001; Miller 2003; Gregory and Waterfield 2008; Broadie 2011) do not suspect, or even mention, the fundamental nature of the incommensurability between the two fundamental triangles, and therefore between the primary earth and each of the other three primary bodies.

Scholars believe that earth does not in any way interact with the other three kinds of bodies and are unable to understand why Plato appears to isolate the earth from the other three kinds. Thus, e.g., Cornford and Zeyl try to justify the situation, presenting it as a necessary evil following Plato's decision to introduce the correspondence of the traditional "elements" with the four canonical solids:

> The *exclusion of earth* from the cycle of transformation is simply a consequence of the decision to assign the cube to earth. Cornford 1937, p. 215–6
> The *exclusion* is driven by *his theoretical commitments*... Plato was *eager* to assign a distinct solid to each of the four kinds. Zeyl 2000, p. xix

Pohle's 1971, p. 46, even timid realization of the fundamental role of incommensurability between the two triangles and therefore between the primary earth and each of the other three primary bodies is definitely the exception:

> The fact that Plato appears at 54A to leave open the possibility that some mathematical conjecture might be disproved with the concomitant destruction of his "too long" a reason why his elements are best, certainly does not rule out considerations of areal *incommensurability*. Issues having to do with the nonexistence of transformation reactions between earth particles and the other three kinds supply further indirect evidence that Plato was aware of the problems raised by areal *incommensurability*, as does the Theaetetus.

As a result, authors in general follow Cornford 1937 (p. 162), in erroneously believing that the primary bodies are themselves sensible bodies, while in fact the primary bodies replace and substitute for the intelligible Being as the cause of the sensibles.

[4]. There is no realization or agreement among scholars (a) that the Receptacle coincides with the "diakena" of the greater primary body, and (b) that the "diakena" in turn coincide with the "hedrai"/faces of the greater primary body.

Thus, Broadie 2011, p. 238, differentiates the Receptacle from the primary bodies:

> Timaeus provides *two accounts* of the genesis of the four materials: one in which the Receptacle is presented as the 'third kind' along with the two metaphysical kinds familiar from the first beginning; and one in which god constructs the elements geometrically. ...
> the Receptacle and its content are whatever they need to be, in order to ensure that the elements are free of any metaphysically primordial self-sufficient agenda that could interfere with their subservience to the intelligence that made the cosmos.

In fact, both accounts are vivid and imaginative descriptions of the same geometric anthyphairetic inequalities, and the Receptacle account is no more suggestive of participation to the intelligible than the openly geometric one. Participation is assured via the Soul of the World, a claim independent of both accounts.

Gregory 2001, p. 36, correctly differentiates the Receptacle from geometric atomism:

> Geometrical atomism (GA) is introduced at 53c. By geometrical atomism I mean the theory that the elements (earth, water, air, fire) can be analysed into three-dimensional particles of definite shape (cubes, octahedra, eikosahedra, tetrahedra, which I shall call 'atoms', in the modern sense), and that these particles can be further subdivided into planes, and that these planes can be further subdivided into one of two types of triangle. GA does not sit entirely easily with the receptacle passage. It may develop or modify the receptacle theory, and certainly it has a considerable bearing on the nature of the receptacle. At the very least we need to think carefully about how the entities proposed by GA relate to the receptacle. What is undeniable is that the rest of the Timaeus (53c *ad fin*) discusses the phenomena in terms of GA and not the receptacle.

However, the role of the primary bodies is erroneously described as Geometric Atomism GA by Gregory, because it is not realized that incommensurability and its approximation by "convergents" are at work. As we have shown, the precise relation between Receptacle and primary bodies is the following: The Receptacle coincides with the faces/"diakena"/"hedrai" of the greater primary body, its Content being the smaller primary body, the generated "confounded" dyad the sensible body.

[5]. Brisson and Ofman 2020. The authors correctly reject interpretations of *Timaeus' Receptacle* in terms of "atomism," citing the existence of incommensurable magnitudes, but they fail to realize the fundamental importance of incommensurability and of periodic anthyphairesis for understanding (all of Plato, and in particular) the Receptacle. The authors spend quite a bit of time attempting to dissociate the *Timaeus* triangles from the "indivisible lines," not realizing that Plato in the *Parmenides*, as Aristotle correctly states, strongly supports their existence, whose paradigm is the One of the second hypothesis, rejecting at the same time the geometric point, whose paradigm is the One of the first hypothesis, without in the least compromising the infinite divisibility of geometric magnitudes (cf. Negrepontis 2019, Sect. 3).

[6]. Harte 2010, p. 140

> On this view, the reality of something being fi re comes precisely from the formal mathematical shaping the demiurge imposes, a fact that goes hand in hand with the view that the being of Fire—its formal nature—is constituted by something **essentially intelligible**, and not perceptible.

The geometrical/mathematical content of the four primary bodies does not endow them with some participation to the intelligible. This participation of the sensibles to

the intelligible is assured only by the passage 58a4-b8 (in conjunction with the participation of the Soul of the world in the intelligible), which Harte does not invoke.

Epilogue: The Debt of *Timaeus*' Receptacle to Theaetetus

The dedication of a work on the Receptacle in Plato's philosophic dialogue *Timaeus* to the mathematician Theaetetus calls for some justification. Throughout our present work, our thesis is that behind *Timaeus*' Receptacle one senses the mathematical achievements of the great mathematician Theaetetus.

The canonical comparison of Triangle A and Triangle B (Sect. 7), on the basis of which alone it is possible to show that these triangles are incommensurable, needs fine computations relating the sides of the faces of a canonical solid to the diameter of the sphere in which it is comprehended, found in the second half of Propositions 13, 15, 18 of the Theaetetean Book XIII of the *Elements*.

The mathematical Proposition in Sect. 4 on the generalized side and diameter numbers (modern "convergents" of continued fractions), originated by the Pythagoreans, must owe a great deal to Theaetetus, as the Proposition is needed for a reconstruction of the proof of his great Theorem (essentially in Sects. 7, 8, and 9) stating the following: If a,b are line segments, such that $a > b$, a,b incommensurable, and a^2, b^2 commensurable, then the anthyphairesis of a to b is palindromically periodic. In Negrepontis 2018, it is shown (a) how the study of the *Politicus* dialogue leads to the certain conclusion that Plato had perfect knowledge of this Theorem, and (b) how the Theaetetean Book X of the *Elements* contains all the tools necessary for the proof of this Theorem, in particular the notions of the *apotome* line and of the line *of two names*, and principally their conjugacy in Propositions X.112–114. A complete proof of the palindromic periodicity theorem, using only the tools of Book X of the *Elements*, is given in Negrepontis (Notes by V. Kleftaki), 2003.

For the definition of the primary bodies and the Third Kind (Sects. 6 and 7), Plato needs the laborious constructions of the first half of Propositions 13–16 of the Theaetetean Book XIII of the *Elements*.

Plato claims that the Third Kind participates in the intelligible and generates sensibles so as to eliminate the infinite kosmoi (Sects. 8, 9, and 10); Plato needs again the very essential Propositions of Book XIII.13–18 on the comprehensibility in the sphere of the canonical solids and on their uniqueness.

Abstract

In the present chapter, we provide a novel interpretation of the concept of Plato's and Xenocrates' *indivisible line*, in fact, we show that indivisibility is just another description of the Platonic intelligible true Being. Our claim and arguments are based on our earlier interpretation of Plato's intelligible Being as the philosophic analogue of a dyad of opposite kinds in periodic anthyphairesis (as revealed primarily in the *Meno*, the second hypothesis of the One in the *Parmenides*, and the *Sophist*), and take into account the ancient sources on the indivisible by Plato (*Sophist, Phaedrus, Republic, Philebus*), Aristotle (*Metaphysics*), Proclus, and Simplicius. Additional arguments, based on Zeno (Dichotomy Paradox), and Aristotle (*Physics,* and the pseudo-Aristotelian *On Indivisible Lines*), establish that Zeno's true Being is also indivisible. Earlier attempts by modern Platonists were not successful, mainly because these have not taken into account the geometric/anthyphairetic nature of a true Being.

1 Introduction

As was acknowledged by A. E. Taylor in 1960 and more recently by M. Rashed (2013), Plato's and Xenocrates' *indivisible line* remains a mystery for the scholars on Plato (Sect. 3). The chapter aims to resolve the mystery and provide a satisfying interpretation of Platonic indivisibility, based on our fundamental interpretation of an intelligible Being as the philosophic analogue of a dyad in periodic anthyphairesis.

The Division of the intelligible Being Noble Sophistry in the *Sophist* 226b1-231b8 and the description of the Division of every intelligible Being in the *Phaedrus* 277b5-c6 passage, in conjunction with our anthyphairetic interpretation of the Divisions in the *Sophist* (Negrepontis 2012), quickly lead us to the conclusion that an intelligible Being becomes "indivisible" exactly at the moment that the Logos Criterion establishing anthyphairetic periodicity is instituted (Sects. 2 and 4).

The exact sense in which an intelligible Being becomes indivisible is lucidly described by Proclus and Simplicius (Sect. 5). For our interpretation of indivisibility (given in Sect. 6), we take into account our earlier interpretation (in Negrepontis 2024) of the definition of dialectic number, namely the number with equalized units, in an intelligible Being, in the second hypothesis of the *Parmenides* and in the *Sophist,* in terms of the "plus one rule," and its finiteness, resulting from the periodicity of the set of ratios of successive anthyphairetic remainders. The identification of the kinds (eide) with the units of the dialectical number leads to the indivisibility of the intelligible Beings, and of course, does not affect the divisibility *ad infinitum qua* magnitudes.

Aristotle's mysterious *Metaphysics* 992a19-22 passage, on Plato's rejection of the point in favor of the indivisible line as the correct foundation of Geometry, is now understood in terms of the rejection of the One of the first hypothesis, partless as a geometric point, versus the acceptance of the self-similar One of the second hypothesis in the *Parmenides* by Plato, both as a true Being and as the foundation of Geometry and Arithmetic (Sect. 7).

In conclusion, the *indivisibility* of an intelligible Being is simply a form of poetic license (a "screen of concealment," as Proclus has it) that allows the transfer, using the *plus one rule* enunciated in the *Parmenides* 148d-149d, of the periodicity of the sequence of the ratios of the successive remainders of the anthyphairesis of the intelligible Being into the finiteness of the number of parts.

The fact that the true foundation of Geometry and Arithmetic is by means of the intelligible Being is expanded in the *Republic* 510b4-511c2 and 533b6-d3, 534b3-d2, where the kinds (eide) generated by the philosophical anthyphairetic Division are

identified with the hypotheses (definitions and postulates) of the geometers, from which the geometers derive, moving downwards/synthetically, the whole body of mathematical propositions. However, the geometers, keep their hypotheses unmoved and undivided, as entities known and true, although they are not, and are content to move downwards, synthetically and deductively to a large extent because of their use of sensible geometric diagrams; thus, the geometers are unable to move upwards, analytically, by a philosophical analogue of the anthyphairetic division of the hypotheses and Logos anthyphairetic periodicity, achieving the status of anhupotheton/hypothesis-free, namely, the status that no new hypotheses/kinds (eide) are generated anymore, exactly the status of indivisibility. Thus the *Republic's* criticism of the geometers fully confirms the identification of the true, intelligible Being with the indivisible line (Sect. 8). The close relation of the upward movement with anthyphairetic division, Logos, and Analysis, while Synthesis and Deduction is alloted to the downward movement, but also with the generation of Geometry and Arithmetic from the intelligible Being, analyzed by Negrepontis and Lamprinidis (2008), is outlined in Sect. 9.

Sections 10, 11 and 12 examine the connections of the indivisible line, not only with Plato's intelligible Being, but, going backward in time, with the second version of Zeno's Dichotomy Paradox (stated in Aristotle's *Physics* 263a-b), both in Aristotle's *Physics* and in the pseudo-Aristotelian work *On Indivisible Lines*.

The passage *On Indivisible Lines* 968a18-b4 on the second version of Zeno's Dichotomy Argument, traditionally considered as hopelessly obscure, is recognized as an instance of Zeno's Basic Argument (presented in *Parmenides* 127d6-128a3), where the almost contradictory Compresence of Opposites property of the true Beings is the numbering of the infinites; the general interpretation of Zeno's Basic Argument, given in Negrepontis (2023a), applied to this instance, shows that Zeno's true Being is identified with the indivisible line (Sect. 12).

In Sect. 10, we obtain the identification of the two Platonic infinites, the dialectical (already infinite, based on the Logos Criterion) versus the eristic, in the *Philebus* 16c5-17a5, with the two Aristotelian infinites, the actual and the potential, respectively, in Aristotle's *Physics*. One basic argument for the identification of the Philebean dialectical infinite with the Aristotelian active infinite is that both are closely associated with the equalization of opposites, fundamental for Plato's philosophy and rejected as impossible by Aristotle.

In Sect. 11, we employ the identification obtained in Sect. 8 to establish the identical nature of Zeno's true Being (in the form of the second version of Zeno's Dichotomy Paradox) and Plato's intelligible true Being (in the form of the definition of the Soul as an entity in self-motion in the *Phaedrus* 245c5-d7). The reason for this identification is that both are deemed impossible to exist because each is an actual infinite (Plato's Soul in *Physics* 257a34-b20, Zeno's true Being in Physics *263-264*).

It follows from Sects. 10, 11 and 12 that the indivisible line is identified not only with Plato's intelligible Being, but also with Zeno's true Being.

2 Periodic Anthyphairesis and Theaetetus' Logos Criterion

2.1 The Concept of Anthyphairesis

Let a, b be two natural numbers or magnitudes (e.g., line segments), with $a > b$.

We measure the great a with the small b and find how many small bs are needed to cover the large a. There are then a natural number k_0, the quotient, and c_1, the remainder, such that

$$a = k_0 b + c_1, \text{with } c_1 < b.$$

This is the first step of the anhyphairesis of a to b.

If c_1 is zero, this is the end of the process. Otherwise, a new pair of great and small is formed, namely the pair $b > c_1$. Notice that the role of b is reversed: in the first step b is small, and in the second step b is great.

We repeat the process. There are a natural number k_1 and c_2, such that

$$b = k_1 c_1 + c_2, \text{with } c_2 < c_1.$$

We continue in this way:

$$c_1 = k_2 c_2 + c_3, \text{with } c_3 < c_2,$$
$$\ldots$$
$$c_n = k_{n+1} c_{n+1} + c_{n+2}, \text{with } c_{n+2} < c_{n+1}$$
$$\ldots$$

2.2 Finite and Infinite Anthyphairesis

- If this process ends at some point, namely for some index n, the remainder c_n divides the immediately previous remainder c_{n-1} ($c_{n-1} = k_n c_n$), then we say that the anthyphairesis of a to b is *finite*.

  This is always the case if a and b are natural numbers, and the last remainder c_n is then the *greatest common measure/divisor* of a and b (Propositions VII.1 & 2 of the *Elements*).
- If this process does not end, then we say that the anthyphairesis of a to b is *infinite*. This can happen only if a and b are not natural numbers. It is then proved that a and b do not have any common measure, namely that a and b are *incommensurable*:

Proposition X.2 of the *Elements*
If a and b are magnitudes, $a > b$, and the anthyphairesis of a to b is infinite, then a and b are incommensurable.

Note that in this case there is an infinite, strictly decreasing sequence of remainders:

$$a > b > c_0 > c_1 > c_2 > \ldots > c_n > c_{n+1} > \ldots.$$

2.3 Periodic Anthyphairesis

The most important case of infinite anthyphairesis is the periodic one.

An anthyphairesis is periodic if the sequence of quotients

$$k_0, k_1, k_2, \ldots, k_n, k_{n+1}, \ldots$$

is a periodic sequence of natural numbers.

2.4 The Theaetetean Theory of Ratios of Magnitudes

The Pythagoreans had an excellent theory of proportion for natural numbers (Book VII of the *Elements*), and, probably, for commensurable magnitudes, but they definitely did not have a theory of proportion for magnitudes.

Aristotle's *Topics* 158b24-159a2, a passage important for the history and reconstruction of Greek mathematics, informs us that before the Eudoxian theory of ratios of magnitudes presented in Book V of the *Elements*, there was an earlier theory based on the following definition.

Definition (Def. V.3 in Euclid's Elements) Two magnitudes a and b possess ratio a/b only if a and b are *homogeneous* (homogene) (namely only if a and b are both straight lines, or both circular lines, or both surfaces, or both volumes).

Definition If a, b are homogeneous magnitudes and c, d are homogeneous magnitudes, then

$$a/b = c/d \text{ if and only if } \mathrm{Anth}(a, b) = \mathrm{Anth}(c, d)$$

(where Anth(a, b) denotes the sequence of successive *quotients* of the anthyphairesis of a to b).

Although Aristotle does not mention the creator of this theory, it is generally accepted that the theory of ratios based on anthyphairesis is due to Theaetetus. A theory of ratios based on this pre-Eudoxian definition, if it were meant to be a theory as general as the Eudoxian theory, would need *Eudoxus' condition* (Def. 4 in Book V. of the *Elements*), and so would be historically untenable. Knorr (Knorr 1975) reconstructs such a theory, but, as carefully noted by Knorr, his crucial Theorem

6, p. 338, the analogue of the fundamental Eudoxian Proposition V.8 of the *Elements*, makes essential use of Eudoxus' condition (V, Def. 4).

There is however evidence that this pre-Eudoxian theory applied only to a limited class of pairs of magnitudes, chiefly the lines that are rational with respect to an assumed line, in the sense of Definition 3 of Book X of the *Elements* – hence the term "alogos" ("ἄλογος") for those ratios whose square is not commensurable. One anonymous comment in *Scholia in Euclidem* V.22 (eds: Heiberg and Stamatis 1977) alludes to a restricted, in fact, quadratic, pre-Eudoxian theory of magnitudes, and another, *Scholia in Euclidem* X.2 (eds: Heiberg and Stamatis 1977), criticizes the general Eudoxian theory, clearly from a Platonic point of view and in favor of the earlier restricted quadratic theory of ratios of magnitudes, which was quite adequate for the purposes of dealing with quadratic incommensurabilities, and for which, as can be shown, there is no need to appeal to Eudoxus' condition.

The primitive *Pythagorean method of preservation of Gnomons/Application of Areas* for finitizing and obtaining full knowledge of the infinite anthyphairesis of diameter to side, evolved, in Plato's time, into the more sophisticated and general *Theaetetean Criterion of [the preservation of] Logos* for establishing periodic anthyphairesis. The formulation of such a Criterion presupposes a theory of ratios and proportions of magnitudes. With this definition of proportion, the Logos Criterion takes the following form:

2.5 Proposition. The [Theaetetean Preservation of] Logos Criterion for Anthyphairetic Periodicity

Let a, b be two line segments, with a > b, their anthyphairesis given as follows:

$$
\begin{aligned}
a &= k_0 b + c_1, & b &> c_1,\\
b &= k_1 c_1 + c_2, & c_1 &> c_2,\\
&\cdots\\
c_{n-1} &= k_n c_n + c_{n+1}, & c_n &> c_{n+1},\\
c_n &= k_{n+1} c_{n+1} + c_{n+2}, & c_{n+1} &> c_{n+2},\\
&\cdots\\
c_{m-1} &= k_m c_m + c_{m+1}, & c_m &> c_{m+1},\\
c_m &= k_{m+1} c_{m+1} + c_{m+2}, & c_{m+1} &> c_{m+2},\\
&\cdots
\end{aligned}
$$

and assume that there are indices n < m such that $c_n/c_{n+1} = c_m/c_{m+1}$

[namely, $\mathrm{Anth}(c_n, c_{n+1}) = \mathrm{Anth}(c_m, c_{m+1})$] ("Logos Criterion").

(in particular, assume that there are indices n<m, such that $c_n c_{m+1} = c_m c_{n+1}$).

Then the anthyphairesis of a to b is eventually periodic, in fact Anth(a, b) = [k_0, k_1, . . ., k_n, period (k_{n+1}, k_{n+2}, . . ., k_m)].

The *Proof* is an application of the Theaetetean definition of proportion. Thus,

$$\begin{aligned}
&\mathrm{Anth}(a,b) = \\
&[k_0, k_1, \ldots, k_n, \mathrm{Anth}(c_n, c_{n+1})] = \\
&[k_0, k_1, \ldots, k_n, k_{n+1}, k_{n+2}, \ldots, k_m, \mathrm{Anth}(c_m, c_{m+1})] = \text{(by Logos Criterion)} \\
&[k_0, k_1, \ldots, k_n, k_{n+1}, k_{n+2}, \ldots, k_m, \mathrm{Anth}(c_n, c_{n+1})] = \\
&[k_0, k_1, \ldots, k_n, k_{n+1}, k_{n+2}, \ldots, k_m, k_{n+1}, k_{n+2}, \ldots, k_m, \mathrm{Anth}(c_m, c_{m+1})] = \text{(by Logos Criterion)} \\
&\ldots \\
&\mathrm{Anth}(a,b) = [k_0, k_1, \ldots, k_n, \text{period } (k_{n+1}, k_{n+2}, \ldots, k_m)].
\end{aligned}$$

2.6 The Already Infinite (Hede Apeiron) in the *Philebus* 16e1-2 Coincides with the Theaetetean Logos Criterion

The Theaetetean Logos Criterion for anthyphairetic periodicity plays a pivotal role in Plato's philosophy, as seen in the *Meno*, in the second hypothesis of the *Parmenides*, and in the *Sophist's* Divisions. The Logos Criterion can be understood as follows: once the Logos Criterion has been established at some *finite* stage of the process of anthyphairesis, we then have established periodicity and thus infinity of the process, and thus at some *finite* stage we have *already arrived at infinity.* In fact, this is exactly the way, as *already infinite* (*hede apeiron*), in which Plato describes the Logos Criterion for anthyphairetic periodicity in the *Philebus* 16e1-2 (as results from the comparison of the second hypothesis in the *Parmenides* with the *Philebus* passage 16c-17a (given in Negrepontis 2024, Sect. 5).

3 Plato's and Xenocrates' *Indivisible Lines* Are Considered Mysterious by Modern Scholars

The *indivisible line*, formally introduced by Xenocrates, but mentioned informally by Plato is something of a mystery for modern scholars of Plato.

A. E. Taylor (1960, p.505–506), writes:

> Plato stated that the "point" was a "fiction of the geometers," and spoke, instead, of the "starting point of the line" (Met. A 9920 20) . . ..
>
> What Plato may have meant by the expression *[[indivisible line]]* we can only conjecture. As a conjecture, I offer the suggestion that his intention is precisely to deny the conception attributed to some Academic, apparently Xenocrates, by the Peripatetic tract. A line, however short, is *"indivisible"* in the sense that you cannot divide it into elements which are not themselves lines in other words, it is a "continuum."

This is certainly not a satisfactory explanation. It is unsupported by ancient sources, it would imply that *every* line is an indivisible line, and it is not explained how such an interpretation would be of any help to Plato in finding a better foundation for Geometry.

Taylor's failure to recognize, in his 1960 work, the anthyphairetic periodicity as the underlying cause of the indivisibility of every intelligible Being (as I will explain in the sequel) is certainly disappointing, because Taylor (1926) was, as far as we know, the first modern scholar of Plato to understand, albeit in an incomplete manner, the connection of platonic philosophy with infinite anthyphairesis.

M. Rashed (2013, p. 106–107) writes

> These remarks may account for Aristotle's *mysterious attribution* to Plato of a theory of *indivisible lines.* According to Aristotle, Plato considered the geometrical point as a doctrine (δόγμα) put forward by geometers, i.e., by geometers only. As such, the geometrical point is deprived of any real existence. Moreover, Plato held some lines to be *indivisible*. To my knowledge, *commentators have never really explained this doctrine.*

4 The *Indivisibility* of Plato's Intelligible Being in the *Sophist* 226b1-231b8 and the *Phaedrus* 277b5-c6

Although Plato does not speak explicitly about the indivisible property of an intelligible Being, there are at least two instances in which he definitely and revealingly alludes to it.

4.1 The *Indivisibility* of the Intelligible Being Noble Sophistry in the *Sophist* 226b1-231b8

We have examined elsewhere (Negrepontis 2023b) Plato's definition of intelligible Beings by the method Name and Logos in the *Sophist*, and concluded that Name stands for the philosophical analogue of the anthyphairetic division of a dyad, and Logos for the philosophical analogue of Theaetetus' Logos Criterion for periodic anthyphairesis, thus exhibiting the intelligible Being as the philosophic analogue of a dyad in periodic anthyphairesis. The examples Plato uses in the *Sophist* are the intelligible Beings of the Angler, the Noble Sophistry, and the Sophist. In the definition of the Noble Sophistry Plato, rather unexpectedly introduces a fleeting, but quite revealing, question about the Indivisibility of the intelligible Being to be defined.

We start with *the art of discrimination* A (diakritiken [technen], 226c8).

The art of discrimination A is divided into two kinds (duo eide, 226c10-11), *the discrimination of like from like* B1, and the discrimination of worse from better A1 (226d1-3), named *purification* (katharmos, 226d10).

Purification A1 is divided into purification of the body B2 and *purification of the soul* A2 (227c7-9).

Two different kinds of vices (kakias, 227d9) of the soul call for two different kinds of purification of the soul A2:

- a kind of disease (noson, 228d7, e3) of the soul, including cowardice (deilian, 228e2, 229a3), insolence (hubrin, 229a3), injustice (adikian, 228e3, 229a3), calls for *[harsh] purification by the imposition of Justice* B3 (Dike, 229a5), akin to medicine (iatrike, 229a1) required for the disease of the body, and
- a kind of deformity (aischos, 228e5) of the soul, ignorance (agnoia, 228d10), calls for *[soft] purification by Instruction* A3 (Didaskalike, 229a9), akin to Gymnastics (gumnastike, 229a1) required for the deformity of the body. 227d-229a.

The difference between the imposition of Justice B3 and the provision of Instruction A3 is certainly the striking difference between a *harsh purification* and a *soft purification*, respectively, (as we have added in brackets).

Next, Instruction A3 is divided into

- instruction in [lowly] *handicraft* B4 (demiourgikas didaskaleias, 229d1-2), and
- [exalted] *education* A4 (paideia, 229d2-3; paideutike 231b5), as provided mainly in Athens (enthade, 229d2), but also among nearly all the Hellenes (229d4).

At this point, the Eleatic Stranger is asking the *crucial question*:

> [Stranger] But we must examine further and see whether it is *already (hede*, 229d5*)* an *indivisible* (*atomon*, 229d5) whole or still admits of division important enough to have a *name.*229d5-6

did the Division scheme *already* (hede) reach the status of an *indivisible* whole (*atomon hede esti pan*, 229d5-6),

or does it still admit a division worthy of a name (tina echon diairesin axian eponumias, 229d6)?

This question suggests some concept of finiteness for division. But finiteness appears to run counter to our interpretation of the Division as the analogue of periodic, hence infinite, anthyphairesis, and in favor of the standard interpretation treating these definitions as some sort of Linneus biological strictly finite divisions. So this question on indivisibility is crucial and must be answered convincingly, if we are to obtain the correct interpretation of the nature of these divisions. We postpone our answer after we consider the way the division finally comes to an end.

The immediate answer given by the Eleatic Stranger is that there is still one more division step (eti schizesthai, 229d8), as follows:

> Education A4 is next divided into a *rougher* method (*trachutera hodos*, 229e1-2), the traditional method of *admonition* B5 (*nouthetetike*, 230a3), and another *smoother* section (*morion leioteron*, 229e2), based on cross-questioning (elegchon, 230d7), the cross-questioning (elegchon) of empty conceit of wisdom (peri ten mataion doxosophian, 231b5-6), *the art of noble sophistry* A5 (genei gennaia sophistike, 231b7-8).

At this point, it becomes clear that the *Logos Criterion* of periodicity has been reached; indeed,

Justice B3 (rougher purification of the soul)/Instruction A3 (smoother purification) = Admonition B5 (rougher Education)/Noble Sophistry A5 (softer Education).

$$\textit{Logos criterion}\ \ \mathrm{B3/A3} = \mathrm{B5/A5} = \mathrm{harsh/soft}$$

[Plato. Plato in Twelve Volumes, Vol. 12 translated by Harold N. Fowler. Cambridge, MA, Harvard University Press; London, William Heinemann Ltd. 1921, including the *Sophist*, modifications by the author]

According to our interpretation, the definition of Noble Sophistry is complete, and we have attained full knowledge of the infinite periodic anthyphairesis of the intelligible Being *Noble Sophistry*. It is also tacitly clear that, together with the full knowledge obtained by the Logos Criterion, the status of Indivisibility is meant to have been achieved. The question is: in what sense is the intelligible Being indivisible, once the Logos Criterion is achieved? Before answering this question, we will look at one more occurrence where Plato calls an intelligible Being indivisible once the Logos Criterion has been reached.

4.2 The *Indivisible Line* and Logos in the *Phaedrus* 277b5-c6

Socrates. Before someone obtains *knowledge* (eidei) of the truth about each of those he *sets logoi* (legei, 277b6) [speaks] (or writes, he must be able to define (horizesthai, 277b6) everything; and having defined (horisamenos, 277b7), he must obtain *knowledge* (epistethei, 277b8) by *dividing (temnein*, 277b7*) according to kinds (kat' eide*, 277b7*) till the indivisible (mechri tou atmetou, 277b7)*; in the same way (kata tauta) understanding about the nature of the soul, by finding out the kind adapted to each such nature, this is how he sets and adorn the *Logos (ton logon, 277c2)* [*discourse*], giving elaborate and harmonious *logoi* (*logous*, 277c3) [*discourses*] for the complex soul, and to the simple [*logoi, 277c3*] [talks] for the simple soul. Previous to that, it is not possible to use artfully (technei) the genus of *Logoi*

> *(logon, 277c5)* [*speak*], either for purposes of instruction or of persuasion, as the preceding *Logos* (logon, 277c6) [*discussion*] has made clear.

[Plato. Plato in Twelve Volumes, Vol. 9 translated by Harold N. Fowler. Cambridge, MA, Harvard University Press; London, William Heinemann Ltd. 1925, including the *Phaedrus*, with modifications by the author]

The *Phaedrus* 277b5-c6 is similar to the *Sophistes* passage, in that again the indivisible status is obtained in the Division according to kinds, as in the *Sophistes* situation. But now there is an explicit and insistent reference to the *logoi*, which, according to our interpretation, are clearly the *Logoi*, namely the Theaetetus' *Logos Criterion* instituting anthyphairetic periodicity.

We must take note that H.N. Fowler's classical translation of the passage has mistranslated, in our view, all six occurrences of *log-*, [kept in brackets in the above-translated passage] *legei*, 277b6 by *speak, ton logon*, 277c2 by *discourse, logous*, 277c3 by *discourses, [implied] logoi*, 277c3 by *talks, logon*, 277c5 by *speak, logon*, 277c6 by *discussion*, wholly losing the meaning of the passage. Cf. our remark in Sect. 8.2 for corresponding renderings of the root log- in the *Republic*.

The *Phaedrus* passage makes clear that indivisibility has been attained exactly at the point when the Logos Criterion is achieved, and thus our interpretation must provide a satisfying and convincing state of *indivisibility* of the intelligible Being, keeping at the same time its infinite divisibility, since the intelligible Being is an entity in periodic hence infinite anthyphairetic division!

5 Proclus' and Simplicius' Explanation of the Sense in Which an Intelligible Being Is *Indivisible*

The commentators Proclus and Simplicius provide essential help and guidance for the correct interpretation of the indivisible line.

5.1 Proclus, *Commentary to Timaeus* 2,245,23-246,7

> Why, therefore, should we any longer fear those skillful Peripatetics, who ask us, what kind of *line (grammen)* Plato here assumes? Is it a physical line? But this would be absurd: for this is the end of bodies. Is it then a mathematical line? But this is *not self-motive (akinetos)* and is *not a true Being (ouk ousia)*. Plato however says that the soul is a *true Being* and is separate from bodies. We say, therefore, that they in vain make these inquiries. For long before this, we have not ceased asserting that this line is of true Being *(grammen ousiode)*. And before us, Xenocrates calls *a line of this kind indivisible (atomon grammen)*. For it would be ridiculous for anyone to think that there is an *indivisible magnitude (adiaireton megethos)*. It is evident, however, that Xenocrates thought it requisite to call it *the logos of true Being (ton logon tes grammes ton ousiode)* of a line. But Plato, *for the sake of concealment (di'epikrupsin)*, employed *mathematical names (onomaton)*, as *screens (para-petasmasin)* of the truth of the things, in the same manner as theologists employed fables, and the Pythagoreans symbols (tois sumbolois). Proclus, *Commentary to Timaeus* 2,245,23-246,7

[[*The Commentaries of Proclus of the Timaeus of Plato*, translated from the Greek by Thomas Taylor, London, 1820, vol. II, p. 116–117, With modifications by the author]]

According to Proclus, *Commentary to Timaeus* 2,245,23-246,7, Xenocrates by the term *indivisible line* did not mean the literal indivisibility of a mathematical/geometrical line, something that would be ridiculous and impossible for someone who knew geometry very well and therefore knew the infinitely divisible nature of the geometric line. Proclus clearly refers to the *"self-motive" line*, by means of which Plato defines the soul in the *Phaedrus* 245c5-9, a definition that is practically identical to the definition of the intelligible Being in the *Sophist* 247d-e, and is possible only under the Logos Criterion ("ton logon tes grammes ton ousiode") and anthyphairetic periodicity, resulting in the equalization of the moving/active and the being-moved/passive part, and thus "self-motive." Thus, Proclus' description of the indivisible line leads to the intelligible Being, in which the infinite divisibility is not an issue, and that periodic anthyphairesis does not preclude describing in some philosophical sense the intelligible being as indivisible.

5.2 Simplicius, *Commentary to Aristotle's Physics* 140,6-13, and 142,16-18

Simplicius does provide the exact sense according to which an intelligible Being is indivisible; and what is more, this is in complete agreement with the structure of intelligible Beings as given by the One of the second hypothesis of the Parmenides, and by the Being in the Sophist.

According to Simplicius, *in Physics* 140, 6-13, 142, 16-18, Xenocrates, being a geometric and wise man, could not contradict the geometric principle and did not ignore the nature of magnitude [namely the infinite divisibility of magnitudes, ["ten ep' apeiron tomen"]; by "invisible line" he meant a line that, even though it was divisible *ad infinitum*, nevertheless was not divisible in kind ["eidei diairetton"], namely *the number of kinds was finite*.

5.2.1 Simplicius, *Commentary in Aristotle's Physics* 140,6-13

> Those in the circle of Xenocrates agreed (sunechoroun)
> *only* with the first *part of the statement (akolouthian)* that
> the intelligible Being is One and undivided (adiaireton)
> [namely, that the true Being is One],
> *but* did not agree with the second, that Being is undivided (undivided).
> [translation of the Simplicius passages is by Huby PM & Taylor CCW, 2011]

This sentence, with a rather complex structure, has nevertheless quite a clear meaning. Xenocrates, like Plato, accepted that the true intelligible Being is One, but he rejected that the true, intelligible Being is partless; in other words, Xenocrates, like Plato rejected that the intelligible Being is the partless One of the first hypothesis in the *Parmenides*. That Plato rejected the partless One of the first hypothesis is stated most explicitly in the *Parmenides* 141e. A similar rejection is mentioned by

Simplicius, on the authority of Eudemus, already by Zeno, the precursor of Plato, in his *Commentary to Aristotle's Physics* 97, 9-16 and 138,3-139,3.

> Hence again Being is *not only one* (mede hen monon) *but many* (alla pleio).

Thus Plato's true Intelligible Being is not only One, but One and Many. That an intelligible Being is Many, in fact infinitely many, is a consequence of the fact that the intelligible Being is a dyad (the dyad <One, Being> in the *Parmenides* second hypothesis, the dyad <Being, not-Being> in the *Sophist*) in infinite anthyphairesis. That an intelligible Being is One is a consequence of the periodicity of the anthyphairesis of the dyad, effected by the Logos Criterion, by means of which the two parts of the dyad, and in fact each of the infinite multitude of the remainders/parts is equalized to the whole.

> However, while divided (diaireton), the intelligible Being
> *does not go on to infinity* (me ep' apeiron ienai),
> *but stops* at some *indivisibles* (all' eis atoma katalegein).
> These however are
> ***not*** indivisibles (atoma) in the sense of being *without parts (amere)* and smallest,
> ***but*** divisible (tmeta) and having parts (mere echonta) with regard to the multitude (to poison) and magnitude (ten hulen), while *indivisible (atoma) and primary (prota) with regard to kinds (kinds)*, assuming that there are certain primary indivisible lines (grammas atomous) Simplicius, *in Physics* 140,9-13

5.2.2 Simplicius, *Commentary to Aristotle's Physics* 142, 16–18

> But since *Xenocrates* was also a wise man (sophos aner),
> how did he come to suggest *the indivisible lines (tas atomous grammas)*?
> For he was not ignorant of the [[infinitely divisible]] nature (τὴν [[ep' apeiron diaireten]] phusin) of the *magnitude (the megethous), but he did say that it was not divisible (diairetin) in kinds (τῷ εἴδει).* Simplicius, *in Physics* 142, 16–18

This second Simplicius passage is similar to the first.
We will provide our interpretation of indivisibility in the next section.

6 Our Interpretation of the Meaning of *Indivisibility* of an Intelligible Being

We now explain the precise sense in which Plato's intelligible being is *indivisible*.

6.1 Every Intelligible Being Is a Dyad in the Philosophical Analogue of Infinite Anthyphairesis, Satisfying the Logos Criterion for Periodicity

According to our interpretation of Plato's intelligible Being, as it results from the *Meno*, the second hypothesis of the *Parmenides*, and the *Sophist*, an intelligible Being is the philosophical analogue of a dyad of opposites in periodic

anthyphairesis. We start with our interpretation of In the *Meno* the dyad is, in fact, geometric, it is the dyad of the diameter to the side of a square; in the paradigmatical intelligible Being of the second hypothesis in the *Parmenides* the dyad is <One, Being>; in the *Sophist*, it assumes the general form <Being, not-Being>258a-b (including as special cases the intelligible dyads <Great, not Great>, 257 d-e, <Beautiful, not-Beautiful> 257e, <Just, not-Just> 258a).

Adapting the *Sophist* terminology, an intelligible Being is a dyad <B, N>, where B stands for Being, N for not-Being, such that the dyad <B, N> satisfies the philosophical analogue of periodic anthyphairesis. Thus

(a) The dyad <B,N> satisfies the condition of *infinite anthyphairesis*

$$\begin{aligned}
&B = N + N_1, \text{with } N_1 \text{ equal to a part of B, for short } N_1 < B,\\
&N = N_1 + N_2, \text{with } N_2 \text{ equal to a part of N1, for short } N_2 < N_1,\\
&N_1 = N_2 + N_3, \text{with } N_3 \text{ equal to a part of } N_2, \text{for short } N_3 < N_2,\\
&\ldots\\
&\textit{ad infinitum},
\end{aligned}$$

and thus an *infinite multitude* of parts/anthyphairetic remainders

$$B, N, N_1, N_2, N_3, \ldots$$

is generated.

(b) The *Logos Criterion* for anthyphairetic periodicity

$$B/N = N_{k\text{-}1}/N_k$$

is satisfied for some index k.

6.2 The Dialectical Number defined by Means of the Plus One Rule (*Parmenides* 148d-149d) in an Intelligible Being

Plato wishes to generate Numbers in every intelligible Being. The classical and practically universal way in which numbers are defined in Greek Mathematics is that a number is a finite collection of units. This is the way in which numbers are introduced in Euclid's *Elements*, definition VII.2. The first impulse would be to generate numbers by taking as units the infinite sequence of anthyphairetic remainders

$$B > N > N_1 > N_2 > N_3, > \ldots,$$

and this is in fact the abortive attempt at the beginning of the second hypothesis in the *Parmenides*, leading to failure, because as explained in *Philebus* 56d-e, the units for the numbers as used by the many (we might say the *eristic* numbers) are unequal, while the numbers used by the philosophers (we might say the dialectical numbers) must be equal. Thus Plato realized that the dialectic numbers cannot be introduced by taking into account only the anthyphairetic division but there is a need for the anthyphairetic periodicity, as well, if *equalization* of the anthyphairetic remainders is to be achieved.

The manner in which the *dialectic numbers* are defined is crucial for understanding the sense in which an intelligible Being is indivisible.

Definition of the dialectical number by means of the "plus one rule," Parmenides 148d-149d.

The *dialectical number* of a sequence of terms in succession

$$x_1, x_2, x_3, \ldots, x_n$$

is equal to

$$(\text{the } \textit{number} \text{ of the set of (different) successive ratios } x_1/x_2, x_2/x_3, \ldots, x_{n-1}/x_n) \text{ plus one.}$$

Examples If the sequence consists of one term only, x_1, then no ratio can be formed, and thus the number of the terms is 1.

If the sequence consists of two terms, x_1, x_2, then only one ratio x_1/x_2 can be formed, so that the number of the sequence is $1 + 1 = 2$.

If the sequence consists of the terms x_1, x_2, x_3, then we can form the two ratios x_1/x_2, x_2/x_3. There are two cases to consider:

If the ratios x_1/x_2, x_2/x_3 are unequal, then the dialectical number of the sequence x_1, x_2, x_3 is $2 + 1 = 3$; but if the ratios are equal, $x_1/x_2 = x_2/x_3$, then the dialectical number of the sequence will be $1 + 1 = 2$.

As an example, the sequence $x_1 = 2$, $x_2 = 4$, $x_3 = 5$ has dialectical number 3, but the sequence $x_1 = 2$, $x_2 = 4$, $x_3 = 8$ has dialectical number 2.

We apply now the definition of the dialectical number to the sequence of the successive remainders of the intelligible Being with initial dyad <B, N>, which is infinite, but with a periodic sequence of successive ratios of remainders.

Proposition (*Parmenides* 144d4-e3, Negrepontis 2024)
The *dialectical number* of the sequence of parts of *every* part of the infinite sequence

$$B, N, N_1, N_2, , , , , N_n, N_{n+1}, \ldots$$

is $k + 1$.

Proof

(i) It follows from the Logos Criterion 6.1. (b) that the sequence of k successive ratios

$$B/N, N/N_1, N_1/N_2, \ldots, N_{k-2}/N_{k-1}$$

forms a complete period, repeating itself cyclically *ad infinitum*:

$$\begin{aligned} N_{k-1}/N_k &= B/N, \\ N_k/N_{k+1} &= N/N_1, \\ N_{k+1}/N_{k+2} &= N_1/N_2, \\ &\ldots, \\ N_{2k-1}/N_{2k} &= N_{k-2}/N_{k-1}. \end{aligned}$$

Thus the number of the terms in the sequence

$$B/N, N/N_1, N_1/N_2, \ldots, N_{k-2}/N_{k-1}, \ldots, N_n/N_{n+1}, \ldots$$

is equal to the number of the terms in the sequence

$$B/N, N/N_1, N_1/N_2, \ldots, N_{k-2}/N_{k-1},$$

namely is equal to the number k. By the "plus one rule,"

the *dialectical number* of the infinite sequence $B, N, N_1, N_2, , , , , N_n, N_{n+1}, \ldots = k + 1$.

(ii) By periodicity, the number of the different ratios in the sequence

$$N/N_1, N_1/N_2, \ldots, N_{k-2}/N_{k-1}, \mathbf{N_{k-1}/N_k}$$

is clearly equal to the number of different ratios in the sequence

$$\mathbf{B/N}, N/N_1, N_1/N_2, \ldots, N_{k-2}/N_{k-1}$$

namely the number k, hence

the *dialectical number* of the infinite sequence $N, N_1, N_2, \ldots, N_n, N_{n+1}, \ldots = k + 1$

A similar argument shows that for every n

the *dialectical number* of the infinite sequence $N_n, N_{n+1}, \ldots = k + 1$.

Corollary

(i) The parts B, N, N_1, N_2, . . ., N_n, . . .of the intelligible, Being with initial dyad <B, N> are mutually *equalized* in the sense that

the dialectical number of the parts of B =
the dialectical number of the parts of N =
the dialectical number of the parts of N_n for every n.

(ii) The greatest number (o arithmos pas, *Philebus* 16d8) that can be generated in the intelligent Being is equal to the number k+1 of the length of the anthyphairetic period of the intelligible Being +1.
(iii) The intelligible Being satisfies the fundamental property *One and Many*, since the intelligible Being is Many, in fact infinitely many, but it is also One, in the self-similar sense that all parts are equalized to the whole.

6.3 The Paradox of an Infinite *Multitude* of Parts Versus a Finite *Number* of Parts: The Multitude of the Parts in the Intelligible Being Is Infinite, but the Dialectical Number of These Parts Is Finite

Proof Infinite multitude follows from the infinite anthyphairesis of B to N (as follows from Sect. 6.1).

Finiteness in number follows from the periodical nature of the anthyphairesis of a true Being, and the definition of the dialectic number by the plus one rule (as explained in Sect. 6.2).

Note The statement in Sect. 6.3 is certainly *paradoxical*. The fact that Plato expects that we will indeed find the statement paradoxical is made clear in the *Sophist* 257a8-12 (*kai tauta ou duscheranteon*, 257a8). The fundamental tenet of Plato's philosophy that "not-Being is (a true intelligible Being," can be understood only by having first an understanding of the anthyphairetic nature of a true intelligible Being, namely as a mixture of infinite anthyphairesis and the Logos Criterion, establishing periodicity. The reader is referred to Negrepontis (2024) for details. For traditional attempts by Platonic scholars to explain why not-Being is a Being, the reader may consult Heidegger (1924–25), Frede (1992), and Crivelli (2012).

6.4 The Whole Part B Is *Indivisible* in the Sense that It Is Infinitely Divisible but nevertheless *Unable to Generate New Units* for Dialectical Numbers After the Completion of a Period

We can describe the situation reached in Sects. 6.2 and 6.3 by stating that the part B is infinitely divisible by anthyphairesis, but at some finite stage, no new units for the dialectic numbers are generated, so that the part B is *indivisible* in generating new units for numbers after a certain point.

6.5 *The Units of the Dialectical Numbers* Are the intelligible *Kinds/Eide*

The identification of the units for the dialectical numbers, namely numbers with equalized units, generated in an intelligible Being, with the Kinds/eide of the intelligible Being, is most clearly explained by Aristotle. In fact, Aristotle in *Metaphysics*

(a) states repeatedly, that the Platonic numbers are numbers with *equalized* units (isasthenton 1081a25, 1083b24, 31, 1091a25, isasthenai 1091a26), in agreement with Plato's requirement for the dialectical numbers, and
(b) refers to these Platonic dialectical numbers as *eidetic* (1081a21, 1086a5,8, 1088b34, 1090b35), as consisting of eide/Kinds (987b21-22).

6.6 The Whole Part B Is *Indivisible* in the Sense that It Is Infinitely Divisible in Parts but nevertheless *Unable to Generate New Kinds* After the Completion of a Period

Since in the intelligible Being with dyad <B, N> there are, according to Sects. 6.2 and 6.3, and since, according to Sect. 6.5, the Kinds in the intelligible Being are identified with the Kinds (eide), it follows that

$$\text{there are exactly } k+1 \text{ Kinds (eide)},$$

the immediately next anthyphairetic division step

$$N_{k-2} = N_{k-1} + N_k$$

generates a new remainder N_k, since the anthyphairesis is infinite, BUT this remainder N_k *cannot* be *a new kind (eidos)*, because of the stringent "plus one rule" for the generation of monads/kinds. It is precisely in this sense that from this point on

the intelligible Being is indivisible.

In conclusion, the *indivisibility* of an intelligible Being is simply a form of poetic license (a "screen of concealment," as Proclus has it) that allows the transfer, using the *plus one rule* enunciated in the *Parmenides* 148d-149d, of the periodicity of the sequence of the ratios of the successive remainders of the anthyphairesis of the intelligible Being into the finiteness of the number of parts.

Thus in an intelligible Being, there are as many Kinds as units for the whole dialectical number of the intelligible Being.

The line B is infinitely divisible by anthyphairesis, but at some finite stage, no new eide/kinds are generated, so that the line B is *indivisible* in generating new eide/kinds after a certain point.

6.7 Examples

We compute the number of the Kinds in the intelligible Being *Noble Sophistly*, examined in Sect. 4.1. We compute the kinds from the Division, but starting from the point where there is pure periodicity, namely from the Kind B3 (Justice). The Being Noble Sophistry has *five* Kinds/units for dialectic numbers, namely

B3 (Justice), A3 (Instruction), B4 (Handicraft), A4 (Education), B5 (Admonition),

and becomes indivisible, in the sense that, even though the division, being periodic, proceeds *ad infinitum*, it nevertheless does not have the power to generate new Kinds exactly at the point where the Logos Criterion is established.

The *mean and extreme ratio* (Elements, Propositions II.11 and VI.13) is a purely periodic, and the diameter to the side of a square is an eventually periodic, anthyphairesis, each with a whole dialectical number equal to 2.

6.8 Confirming Evidence for Our Interpretation

Our interpretation explains why the indivisibility occurs exactly at the point of establishment of the Logos Criterion, as in Plato's passages in Sect. 4. Furthermore, our interpretation of the indivisible line in Sect. 6.7 is essentially identical to the description given by Proclus and Simplicius in Sect. 5, recall example.

6.8.1 Simplicius, *Commentary to Aristotle's Physics* 142, 16-18

> But since *Xenocrates* was also a wise man (sophos aner),
> how did he come to suggest *the indivisible lines (tas atomous grammas)*?
> For he was not ignorant of the [[infinitely divisible]] nature (ten [[ep' apeiron diaireten]] phusin) of the *magnitude (the megethous), but he did say that it was not divisible (diairetin) in kinds (τῷ εἴδει).* Simplicius, *in Physics* 142, 16-18"

In addition, our interpretation makes sense of the mysterious Aristotle's *Metaphysics* 992a19-22, as we shall see in Sect. 7 below.

On the contrary, the standard interpretation by Platonic scholars has the Divisions in the *Sophist* to be divisions of strictly finite length, not infinite divisions (as becomes manifestly clear in the Division of the Statesman in the *Statesman*), involving the Logos Criterion and anthyphairetic periodicity, and the reference to indivisibility in the *Sophist* and the *Phaedrus* to simply indicate that we have reached the last step of the finite division. Cf, Crivelli (2012 p.18):

> The division goes on until indivisible kinds are reached (cf. Phdr. 277b7–8; Sph. 229d5–6). If it aims at definition, then only one kind counts as indivisible: the one to be defined. If division aims instead at classification, then only kinds count as indivisible that encompass no subordinate kinds.

7 We Are Now in a Position to Obtain Our Interpretation of the Heretofore Mysterious Aristotle's *Metaphysics* 992a19-22 Passage, Since the One of the First Hypothesis in the *Parmenides* Is Identified with the Geometric Point and the One of the Second Hypothesis in the *Parmenides* Is Identified with the Intelligible, Hence Indivisible, Being

7.1 Aristotle, *Metaphysics* 992a19-22 on Plato's Indivisible Lines

> Further, from what principle will the presence of *the points* (*hai stigmai*) in the line be derived? *Plato* even used to object (diemacheto) to this class of objects (toutoi toi genei) as being *a geometrical fiction (geometrikoi dogmati)*. He gave the name of principle of the line- and this he often posited (touto de pollakis etithei) to *the indivisible lines (tas atomous grammas)*. Aristotle, *Metaphysics* 992a19-22

[[Aristotle, *Metaphysics*, *a revised text with introduction and commentary* by William David Ross, Clarendon Press, Oxford, 1924. With modifications by the author]]

The passage states that Plato rejected the concept of the partless geometric point ("stigme") as a foundational concept of geometry, and opted instead for the concept of the "indivisible line" ("atomous grammas").

According to Aristotle's *Metaphysics* 992a19-22 Plato	
rejects the geometric point	
	accepts the indivisible line
as the true foundation of geometry	

The attentive reader of Plato will doubtlessly have noted that there is no mention of geometric point in his dialogues (although he talks about numbers, straight lines, circles, and angles). It is difficult to conceive of geometry without the concept of geometric point, but Plato suggests just that and replaces it with something mysterious, and seemingly contradictory, *the indivisible line*.

However, we will try to make sense of both, quite unexpected and difficult-to-comprehend, statements in Aristotle's passage.

In fact, we shall see that Aristotle wrote his Metaphysics *passage having open in front of him Plato's* Parmenides, *on which Aristotle's passage is essentially a most natural comment.*

7.2 Aristotle's Passage Is Understood as a Comment on the Comparison Between the First and the Second Hypothesis in Plato's *Parmenides*, Fully Confirming that the Indivisible Line Coincides with the Paradigmatical One of the Second Hypothesis in the *Parmenides*

7.2.1 The One of the First Hypothesis Cannot be the Foundation of Geometry, but the One of the Second Hypothesis Can

7.2.1.a *We first note that the One of the first hypothesis in the* Parmenides *137c5-6 is partless, and thus resembles the geometric point*

- Then there can be no parts of it, nor can it be a whole. 137c5-6

Thus the One of the first hypothesis in the *Parmenides* is partless, like a geometric point.

7.2.1.b *The One of the first hypothesis in the* Parmenides *cannot generate the basic figures of Geometry, the straight line, and the circle, but the One of the second hypothesis does*

7.2.1.c *According to the* Parmenides *137d8-138a1, the One of the first hypothesis, a completely partless entity (according to 137c4-d3), having as a model the geometric point does not have the power to generate the basic geometrical figures, straight line and circle*

> -And it [the One of the first hypothesis in the *Parmenides*] is without figure (aneu schematos), for it participates (metechei) neither of the round (stroggulou)) nor of the straight (eutheosς).
>
> -How so?
>
> -The round (stroggulos), of course, is that of which the extremes are everywhere equally distant from the center.
>
> -Yes.
>
> -And the straight (euthu), again, is that of which the middle obstructs the communication (epiprosthen) between the two extremes.
>
> -It is.
>
> -Then the one would have parts and would be many, whether it participated (metechoi) either of straight (eite eutheos) or of round (either peripherous) figure.
>
> -Certainly.
>
> -Then it is neither straight (euthu) nor round (peripheres) since it has no parts.
>
> -Right. *Parmenides* 137d8-138a1

7.2.1.d *According to the* Parmenides 145b3-5, *the One of the second hypothesis does have the power to generate the basic geometrical figures, straight line, and circle*

While on the other hand, *the One of the second hypothesis*, whose model, as we have seen, is a dyad in periodic anthyphairesis, does have the power to generate the two basic geometrical figures, straight line, and circle.

> -And the one (to hen), apparently, being of such a nature (toiouton on),
> will participate (metechoi an) of some figure (schematos),
> whether straight (etoi eutheos) or round (e stroggulou) or a mixture of the two.
> -Yes, it will. *Parmenides* 145b3-5

7.2.1. According to His Dialogue *Parmenides* Plato	
rejects the One of the first hypothesis 137d8-138a1, which is a partless One, like a geometric point 137c5-6	
	accepts the One of the second hypothesis 145b3-5
as the true foundation of geometry	

7.2.2 The One of the First Hypothesis in the *Parmenides* Is Not a True Intelligible Being, the One of the Second Hypothesis Is a True, Intelligible Being

7.2.2.a *The One of the first hypothesis in the* Parmenides *is* ***not*** *a true intelligible Being*

> -Then if the one has no participation in time whatsoever, it neither has become nor became nor was in the past, it has neither become nor is it becoming nor is it in the present, and it will neither become nor be made to become nor will it be in the future.
> -Very true.
> -Can it then participate in being in any other way than in the past, present, or future?
> -It cannot.
> -Then the one has no share in being at all.
> -Apparently not.
> -Then the one is not at all.
> -Evidently not. 141e3-10

The One of the first hypothesis in the *Parmenides* is definitely not a true, intelligible Being.

7.2.2.b *The One of the second hypothesis is a true, intelligible Being*

> -But since the one participates in time and can become older and younger, must it not also participate in the past, the future, and the present?

-It must.

-Then the one was and is and will be and was becoming and is becoming and will become.

-Certainly.

-And there would be and was and is and will be something which is in relation to it and belongs to it?

-Certainly. 155c8-d6

The One of the second hypothesis in the *Parmenides* is definitely a true, intelligible Being.

7.2.2 *According to his dialogue* Parmenides *Plato*	
rejects *the partless One of the first hypothesis 141e3-10*	
	accepts *the One of the second hypothesis 155c8-d6*
as the true intelligible Being	

7.2.3 The Comparison of Aristotle's *Metaphysics* 992a19-22 with Plato's Two Hypotheses in Plato's *Parmenides* Leads to the Identification of the Indivisible with the Paradigmatical Intelligible Being, the One of the Second Hypothesis

Indeed, **the *One of the first hypothesis*** is a completely partless entity and thus is closely related to the **geometric point**, defined (in Euclid's *Elements*) as a geometric entity without parts.

In addition, the *One of the first hypothesis* is not a true Being and **does not have the power** to generate the two basic geometrical entities, the straight line and the circle, according to Plato's *Parmenides*, in agreement with Plato's view, as reported by Aristotle in the *Metaphysics* passage, that the *geometric point* **cannot** serve as the foundation of geometry according to Plato.

On the other hand, **the *One of the second hypothesis*** is a **true intelligible Being**, and **does possess the power** to generate the two fundamental geometrical figures, the straight line and the circle, according to Plato's *Parmenides*, in agreement with Plato's view, as reported by Aristotle in the *Metaphysics* passage, that the so-called *indivisible line* can serve as the foundation of geometry.

Thus, the comparison of Plato's *Parmenides* with Aristotle's *Metaphysics* passage rather strongly suggests that *the indivisible line* is identified with *the One of the second hypothesis, the paradigmatical intelligible Being.*

Comparing the *Metaphysics* passage with the *Parmenides* passages (in Sects. 7.2.1 and 7.2.2), we conclude that

	The indivisible line must be closely connected or even coincide *with the One of the second hypothesis* in the *Parmenides*

7.2.4 The Identification of Plato's Indivisible Line with the One of the Second Hypothesis in the *Parmenides*

According to the passages examined in Sects. 6 and 7, we may regard the One of the second hypothesis, namely the dyad $a > b$ in periodic anthyphairesis, as an indivisible line in the following exact sense:

The dyad $a > b$ is divisible *ad infinitum*, but after the stage n where the Logos Criterion holds, there are no new logoi/ratios of successive parts/remainders, no new units for numbers, and no new kinds (eide). Thus the paradox that occurs in the "indivisible line," namely that the parts of the "indivisible line" are infinite in multitude, while the kinds ("eide") are only finite, practically coincides with the paradox we have observed in the One of the second hypothesis in the *Parmenides*, namely that the parts of the One are *infinite in multitude*, while the parts of the One are *finite in number*.

We have no difficulty in identifying the "indivisible line" with the One of the second hypothesis in the *Parmenides*. The heretofore mysterious *Metaphysics* 992a passage becomes now fully understandable: according to Plato, Geometry must be founded, not on the geometric point (as was done eventually in Euclid's *Elements),* which is clearly the model for the One of the first hypothesis, but on the One of the second hypothesis in the *Parmenides*, Plato's paradigmatical intelligible Being, and which essentially coincides with the indivisible line.

8 The Hypothesis-Free/Anhupotheton in the *Republic*

(a) *Is a True Intelligible Being*
(b) *Is Indivisible*
(c) *Serves as the Foundation for Geometry*

The hint given in the second hypothesis in the *Parmenides* that the intelligible Being is the true foundation of Geometry (Sect. 7) is greatly expanded in the *Republic.* We outline the relation of the intelligible Being, called *anhupotheton/hypothesis-free principle*, as the foundation of Geometry by considering the *Republic* passages listed below.

Dialectical geometry	Geometry as practiced by geometers
	G1 510b4-6
D1 510b6-9	
	G2 510c2-d3
D2 511b3-7	
D2+ 511b7-c2	
	G3 533b6-c6
D3 533c7-d3	
D4 534b3-d2	

8.1 The Passages *Republic* [D1] 510b6-9, [D2] 511b3-7, [D3] 533c7-d3, [D4] 534b3-d2 Identify the Anhupotheton/ Hypotheses-Free with the Intelligible Being

[D1] *In an intelligible Being, there is an intelligible ascent from the hypotheses to the hypothesis-free principle*

> while there is another section in which it proceeds *from a hypothesis ("ex hupotheseos")* to *a hypothesis-free principle ("ep' archen anhupotheton")*, and in which it makes no use of the images employed by the other section, relying on ideas ("autois eidesi") only and progressing systematically through ideas ("di' auton"). 510b6-9

This passage introduces the unfamiliar term *"anhupotheton"/hypothesis-free*. According to passage D1, the intelligible Being proceeds from hypotheses to the hypothesis-free, without any recourse to sensible images, but using kinds.

From the *Meno*, the *Republic*, the Divisions in the *Sophist,* and the second hypothesis in the *Parmenides*, we have reached an interpretation of the structure of an intelligible Being, in terms of anthyphairetic division (described as *True Opinion*, or *Name*) and the Theaetetus' Logos Criterion for anthyphairetic periodicity (described as *Logos*) (cf. Negrepontis 2019, 2023b, 2019).

The parts/kinds/names in the Divisions of the *Sophist*, but also of the *Statesman*, are systematically referred to as *hypotheses*, as seen by the list that can be found in Negrepontis (2019, Sect. 1.5.4).

[D3] *The most crucial and revealing passage concerning the dialectics in the* Republic *is passage 533c7-d3; according to it, the ascent to the anhupotheton is achieved by "anairousa" the hupotheses*

> ". . .Then," said I, "is not dialectics the only process of inquiry that proceeds (poreuetai) in this manner, *"anairousa" the hypotheses (tas hupotheseis anairousa, 533c8)* toward *the principle itself* {auten ten archen) [the anhupotheton] to find confirmation there? And it is literally true that when the eye of the soul is sunk in the barbaric slough, dialectic gently draws it forth and *leads it up* ("anagei ano") 533c7-d3

Furthermore, we have established in Negrepontis (2019, Sect. 1.6.3), that the crucial statement "tas hupotheseis anairousa," in passage D3, refers to the division of the hypotheses, namely the Division according to kinds.

> *Thus, we interpret the term "hypotheses" in passages D1 and D3 to mean the parts/kinds/ names generated by the anthyphairetic/"antanairetic" division of an intelligible Being.*

[D2] The passage introduces the vital role of *Logos* in an intelligible Being; it is the presence of Logos that forces the hypotheses to be not devoid of motion but to act as springboards and footings toward the hypothesis-free.

> ". . .Understand then," said I, "that by the other section of the intelligible I mean that which *Logos itself ("autos o logos," 511b4)* [Shorey's rendering: reason itself] is in contact with

("haptetai") the power of dialectics ("dialegesthai"), treating its *hypotheses* not as principles ("archas") but truly as hypotheses, footings ("epibaseis"), and springboards ("hormas") so to speak, to enable it *to ascend to the hypothesis-free (anhupothetou*) which is the principle ("archen") of the all 511b3-7

[D4] *The fundamental importance of logos for obtaining the Knowledge of an intelligible Being* 534b3-d2

-And do you not also give the name dialectician to the man who is able to exact *the logos (logon*, 534b3) [Shorey's rendering: account] of the essence of each thing? And will you not say that the one who is unable to do this, in so far as he is incapable of rendering *the logos (logon*, 534b4) [Shorey's rendering: account] to himself and others, does not possess intelligence (noun, 534b5) about the matter?

-How could I say that he does? he replied.

-And is not this true of the good likewise – that the man who is unable to define *using logos (toi logoi*, 534b9) [Shorey's rendering: discourse] and *subtract (aphelion*, 534b9) from all other things the idea of the good, and who cannot, as it were in battle, running the gauntlet of all tests, and striving to examine everything by true Being (ousian) and not by opinion (doxan), hold on his way through all this without tripping (aptoti) *using logos (toi logoi*, 534c3) [Shorey's rendering: reasoning] – the man who lacks this power, you will say, does not really have *knowledge (eidenai*) of the good itself or any particular good; but if he apprehends any adumbration of it, his contact with it is by opinion, not *by knowledge (epistemei*); and dreaming and dozing through his present life, before he awakens here 534b3-d2.

[Plato. Plato in Twelve Volumes, Vols. 5 & 6 translated by Paul Shorey. Cambridge, MA, Harvard University Press; London, William Heinemann Ltd. 1969, including *Republic*, with modifications by the author]

We *note* that the classical P. Shorey translation renders *logos* in 510c7 as *account*, in 511b4 as *reason*, in 533c2 as *account*, in 534b3 as *account*, in 534b4 as *account*, in 534b9 as *discourse*, and in 534c3 as *reasoning*. Cf. Sect. 4.2 for corresponding renderings of log- in the *Phaedrus*.

In passages D2 and D4, the Logos plays a prominent, fundamental role. But, as we have seen in the references to our work cited above,

we interpret the term Logos in passages D2 and D4 to mean the Logos Criterion for anthyphairetic periodicity, by which full knowledge of the intelligible Being is obtained.

Our analysis of the *Republic* passages D1, D2, D3, and D4 shows that

- the hypotheses are the *kinds (eide) of the intelligible Being*,
- the Ascent from hypotheses to higher hypotheses is identical with *the anthyphairetic division and motion* of the kinds, while
- by the "Logos provided to the hypotheses" is meant exactly *the Logos Criterion for anthyphairetic periodicity.*

Thus the structure of the anhupotheton in the *Republic* is identical to the structure of the paradigmatical intelligible Being, the One of the second hypothesis in the *Parmenides*.

8.2 The Term "Anhupotheton" in the *Republic* Suggests the Indivisibility of the Intelligible Being

But why does Plato call the intelligible Being "anhupotheton," namely hypotheses-free?

We first note that by passage D3 of the *Republic,* especially the statement *"anairousa" the hypotheses (tas hupotheseis anairousa, 533c8)*, considered in Sect. 8.2, the principal feature of the hypotheses is their division, in fact their dichotomy, into two higher hypotheses, and then into still higher ones. But the only division there is in an intelligible Being, which according to our interpretation is the philosophical analogue of a periodic anthyphairetic dyad, applies to the parts of the anthyphairetic division. So, the hypotheses must be parts/remainders of the intelligible anthyphairetic division.

On the other hand, the Kinds (eide), called also species or genera, which appear in the Divisions in the *Sophist* and the *Statesman*, as the division proceeds toward the Logos Criterion, are systematically referred to as hypotheses, as shown in the extensive list in Sect. 4.4 in Negrepontis (2019).

Thus the hypotheses appearing in the *Republic* description of the structure of the anhupotheton can be safely identified with the Kinds (eide) appearing in the definition of the intelligible Being. The terminology "anhupotheton" is naturally understood as follows: the hypotheses are the Kinds (eide); with the establishment of the Logos Criterion, there are no more new Kinds (eide), and thus no new hypotheses, and so we have reached the state of hypotheses-free. Thus the term anhupotheton has the force of indivisible, according to our interpretation in Sect. 6.

8.3 According to the Passages *Republic* [G1] 510b4-6, [G2] 511b3-7, [G3] 510c2-d3, the True Foundation of Geometry Is Not the Hypotheses of the Geometers but the Hypothesis-Free/ Anhupotheton

8.3.a In the *Republic* passages G1 510b4-6, G2 510c2-d3, and G3 533b6-c6, Plato criticizes the way the geometers regard the hypotheses, definitions, and postulates, as foundational starting points for Geometry and Arithmetic, and proposes instead that these hypotheses should themselves be founded on the intelligible Being/anhupotheton

[G1] By the distinction that there is one section of it [the intelligible] which the soul is compelled to investigate by treating as images the things imitated in the former division and *starting from hypotheses (ex hupotheseon)*, it proceeds not up to *a first principle (ep' archen)* but *down to a conclusion (teleuten)* 510b4-6

[G2] For I think you are aware that students of geometry and reckoning and such subjects set as *hypotheses (hupothemenoi)*, the odd and the even and the various figures and the three kinds of angles and other things akin to these in each branch of science, and these regard

them *as known (hos eidotes),* and, treating them as absolute *hypotheses (hupotheseis)*, do not deign to render any further *logos (logon, 510c7)* [Shorey's rendering: account] of them to themselves or others, taking it for granted that they are obvious to everybody. They take their start (archomenoi) from *these [hypotheseis]*, and pursuing the inquiry from this point on consistently, *conclude (teleutosin)* with that for the investigation of which they set out. 510c2-d3

[G3] while the remnant which we said did in some sort lay hold on reality – *geometry* and the studies that accompany it – are, as we see, dreaming about being, but the clear waking vision of it is impossible for them as long as they leave the *hypotheses (hupothesesi)* which they employ *without allowing them to move (akinetous eosi)* and cannot give a *logos (logon, 533c2)* [Shorey's rendering: account] of them. For where the starting-point (arche) is something that the person does not know, and the end (teleute) and all that is between (between) is an *intertwining (sumpeplektai)* of things not known, what possibility is there that assent in such cases can ever become *knowledge (episteme)*?
None, said he. 533b6-c6

We can summarize the *Republic* passages G1, G2, and G3 as follows:

The geometers have some *hypotheses*, such as the *numbers* (the even and the odd), the *two figures* (the straight line and the circle), and the *three kinds of angles* (right, obtuse, and acute), which they use as starting points, as principles, and, with no justification, as something they pretend to know. We must note at this point that Plato identifies the *mathematical hypotheses*, namely the definitions and postulates of Arithmetic and Geometry, with the philosophical hypotheses, which are the parts/kinds/names/predicates in the philosophical analogue of the anthyphairetic Division that describes an intelligible Being.

From these hypotheses, the geometers proceed, *not* upwards toward the hypothesis-free, as the dialectician, *but* in the converse direction, downwards to their logical consequences. Since the geometers never employ their hypotheses in order to move upwards to the Logos of periodicity and the resulting hypothesis-free, they do not possess knowledge of the hypotheses, but are in some sort of dream condition, In particular, they do not attain the intertwining of Logoi that forms the circle of periodicity, and thus they have no knowledge of the *beginning, middle, and end* of that period of the whole, as explained in the second hypothesis in the *Parmenides* (145a4-b1).

8.3.b *An informal reconstruction of the generation within the intelligible Being/ anhupotheton of the mathematical hypotheses mentioned in the* Republic *passage G2 510c2-d3*

Plato does not provide details for the generation of the mathematical hypotheses from the structure of the intelligible Being, but we can reasonably reconstruct such a generation. Since we have already attempted this reconstruction, we will refer the reader to Negrepontis (2019, Sects. 1.10 and 1.11).

The dialectical numbers, namely the numbers with equalized units, are generated in the intelligible Being of the second hypothesis in the *Parmenides* and are based on the anthyphairetic periodicity. The whole number generated in an intelligible Being is finite and equal to the number of ratios of successive remainders of the anthyphairesis of the intelligible being plus one. Dialectic numbers are also discussed in the *Republic* 522b8-526e8, *Philebus* 16e-17a, and *Philebus* 56c-d. For details, consult Sect. 6 of the present chapter and Negrepontis (2024, Sects. 3 and 4); (2023a, b, Sect. 1.10.1).

The *straight line* is generated, employing the abbreviated Zeno-like representation of the Platonic Divisions, based on the infinite anthyphairetic division and the "already infinite" (cf. Sect. 1.10.2), *the circle* is generated from the anthyphairetic periodicity (cf. Sect. 1.10.4), and the first three Postulates are derived in a way similar to that outlined by Proclus in his *Commentary to Euclid* 185, 8-21, where Proclus endows the geometric point with the motion of the intelligible Being (cf. Sects. 1.7.3 and 1.10.3).

The *three kinds of angle* and *Postulate 4* of the *Elements* are generated from the Pell property of the side and diameter numbers, the anthyphairetic approximations of the intelligible diameter to the side of a square (*Republic* 510d7-8) (cf. Sect. 1.11).

The main failure of Plato's dialectics lies in its inability to derive within the intelligible Being the *Fifth Postulate*. Platonists believed that such derivation would be possible, perhaps because both each of the intelligible Being and the Fifth Postulate is a finitization of the Infinite, but in quite different ways.

9 The Geometric Analysis Is Connected with the Ascent from Hypotheses to the Anhupotheton in Plato's Intelligible Being, and the Geometric Synthesis and Deduction with Plato's Descent from the Anhupotheton

9.1 Geometric Analysis Is Connected with Plato's Division (and Logos) by Proclus *In Euclidem* 211,18-212,4

> Nevertheless, there are certain methods that have been handed down, the best being the method of *analysis (analuseos)*, which traces the desired result back to an acknowledged principle (archen). Plato, it is said, taught (paradedoken) this method to Leodamas, who also is reported to have made many discoveries in geometry using it.
> A second is the method of *diairesis ("diairetike")*, *dividing ("diairousa")* the genus ("genos") proposed into its natural parts ("kat' arthra"), and which [diairetike] provides a starting point ("aphormen") for the demonstration ("tei apodeixei") of the construction ("tes kataskeues") of the proposed [genus] by means of the division ("anaireseos") of the other [genera]. This method also Plato praised (exumnesen) as an aid (epikouron) in all the sciences (epistemais). Proclus, *In Eucliden* 211, 23-27

Here Proclus appears to correlate the method of Division of a genus into species, the basic tool in Plato's philosophy, with the method of Analysis, a geometric method of which Plato was quite fond. The method of Division of genera into species is certainly the method that Plato exemplifies with his Divisions in the *Sophist* and the *Statesman*, and according to our interpretation, it is an imitation of the geometric method of periodic anthyphairesis.

9.2 The Ascent and Descent in Plato's *Republic* Are Connected with the Analysis and Synthesis, Respectively, in Pappus' *Collection 634,11–636,14* (Negrepontis and Lamprinidis 2008)

One may wonder what would be the relation of the Platonic Division method with Analysis and Synthesis. The close connection of the Ascent from hypotheses to the anhupotheton and the converse Descent with Pappus' Analysis and Synthesis, respectively, as suggested by Proclus' connection (Sect. 9.1), presented in Negrepontis & Lamprinidis (2008) and in Lamprinidis (2015), are outlined here.

Indeed, the abbreviated Zeno-like form of Plato's Division and Logos method in the *Sophist*, by which Plato defines the Angler, the noble Sophistry, and the Sophist, makes it quite reasonable to think of Division as Analysis, and of the successive genera of the Division as higher hypotheses: starting from the initial genus G, in analysis fashion we look for a higher hypothesis: we divide the initial genus G into a and b, and then decide that of the two a,b, the suitable higher hypothesis from which G follows is b, and so on, in quite the same way that geometrical analysis, such as the one by Pappus in the *Collection* 634,11–636,14, is described as a process proceeding from hypotheses to higher hypotheses.

Thus the abbreviated representation of anthyphairetic *Division* in the *Sophist* is precisely the *Analysis*: starting with G, G follows from b, b follows from b_1, b_1 follows from b_2, . . ., b_{n-1} follows from b_n, ending into something *known* b_n, exactly when the Logos criterion, say $a_n/b_n = a_1/b_1$, and Analysis are achieved; while the direction opposite to anthyphairetic Division corresponds to the Synthesis and the Deduction →, namely

$$(\text{Logos Criterion } a_1/b_1 = a_n/b_n) \rightarrow b_n \rightarrow b_{n-1} \rightarrow \ldots \rightarrow b_2 \rightarrow b_1 \rightarrow G.$$

[D2+] *The dialectic descent from the anhupotheton* Republic *511b7-c2*

> again ("palin") having as parts the parts of it [the beginning], so to *move downward* ("katabainei") to the consequences ("epi teleuten"), making use exclusively of intelligible entities, moving on through kinds ("eidesi autois") to kinds ("eis auta") and ending with kinds ("teleuta eis eide"). 511b7-c2

10 The Two Infinites, the Dialectical and the Eristic Infinite, in the Platonic Dialogue *Philebus* 16c5-17a5, Essentially Coincide with the Two Infinites, the Actual and the Potential Infinite, Respectively, in Aristotle's *Physics* 204a-207b

10.1 Plato Accepts the *Dialectical, "Already" (Hede Apeiron) Infinite,* Namely the Anthyphairetically Periodic Infinite Induced by the Logos Criterion, and Rejects the *Eristic Infinite,* Namely the Infinite Established Without the Logos Criterion *Philebus* 16c5-17a5

The claim that the dialectical, already infinite in the *Philebus* 16c5-17a5 is the anthyphairetic periodic infinite induced by Platonic Logos, the philosophic analogue of the Theaetetus Logos Criterion, has been established in Sect. 5 of Negrepontis (2024). We outline the content of the *Philebus* passage.

[1]. The fundamental two properties of an intelligible Being are:
(a) The Being is a mixture of infinite and finite
(b) The Being is (infinitely) many and a self-similar One

> *Socrates* A gift (dosis) of gods to men, as I believe, was tossed down from some divine source through the agency of a *Prometheus*, together with a gleaming fire; and the ancients, who were better than we and lived nearer the gods, handed down the tradition that all the things which are said to be eternal *Beings* (ton aei legomenon einai) consist of *One and Many* (*ex henos kai pollon*) and have inherent in them *the Finite (peras)* and *the Infinite (apeirian)* 16c5-10

[2]. The "already infinite" (*hede apeiron*) is essentially the Logos Criterion for anthyphairetic periodicity, since the Logos Criterion implies periodicity of the ratios of successive remainders, allowing for the definition of the *"whole number" (arithmon panta)* by the plus one rule:

> This being the way in which these [true Beings] are arranged (diakekosmemenon), we must always assume that there is in every case *one idea* (mian idean) of everything and must look for it – for we shall find that it is there (euresein gar enousan) – and if we get a grasp (metalabomen) of *this*, we must look (skopein) next for two, if there be two, and if not, for three or some other *number (arithmon)*; and again we must treat each One (hen hekaston) [of the true Beings] in the same way, until we obtain the knowledge (idei) *not only* (me monon) that the original One is one and many and infinite, *but exactly how many* (alla kai hoposa) it is.
>
> And we must *not* offer (prospherein) the idea of the infinite to the multitude (plethos) *until* (prin) we obtain knowledge (katidei) of its *whole number* (*arithmon panta*) between (metaxu) *Infinite and One*; then *already (hede)* each One (hen hekaston) of the true Beings may be let go (methenta chairein ean) *into the infinite (eis to apeiron)* 16c10-e2.

[3]. The dialectic method, employing the already infinite, is an evolution due to Theaetetus of the traditional Pythagorean way of proving incommensurabilities, while the more recent methods, of proving quadratic incommensurabilities, without the Logos Criterion, presumably the arithmetical nonanthyphairetic proofs employing the Principle of the Least, by Archytas, are called *eristic*.

> The gods, then, as I said, handed down to us this mode of investigating, learning, and teaching one another; but the wise men of the present day make the one and the many too quickly or too slowly, in haphazard fashion (hopos an tychosi), and they put the infinites (apeira) right after (euthus) One and (ekpheugei) the intermediate ones (ta mesa), and it is this which distinguishes between the *dialectic* and the *eristic* methods of discussion.16e3-17a5

Thus, the crucial features of the dialectic infinite that differentiates it from the eristic infinite are (a) the Logos Criterion of periodicity, (b) the resulting equalization of the parts/Kinds, and finally (c) the generation of dialectical numbers. Because infinity is established by the Logos Criterion, something that occurs at a finite stage of the anthyphairesis, Plato calls the dialectical infinite the "already" infinite (hede infinite).

10.2 Aristotle in *Physics 204a-207b* Accepts the Potential Infinite but Rejects the Actual, Completed Infinite

10.2.1 The Definition of the Potential Infinite by Aristotle in *Physics*

For there will *always (aei)* be something to take *outside (exo). 206b17-18*

> The infinite turns out to be the contrary of what it is said to be.
> It is not what has nothing outside (meden exo) it that is infinite,
> but what always has something outside (aei ti exo) it. 206b33-207a1
> The translation of these and following passages from Aristotle's Physics is from Hardie RP & Gaye PK, 1984

We note that Aristotle considers that his definition is new and goes against the usual notion of infinite at the time; we conclude that the older notion of the infinite was the completed infinite.

10.2.2 Aristotle's Rejection of the Actual Infinite in *Physics*

It is plain, too, that the infinite *cannot be* an actual (energeiai) infinite and a Being (ousia) and principle (archen). 204a20-21

Now, as we have seen, magnitude is **not** actually infinite (kat' energeian apeiron). 206a16 but by division (diairesei) it is infinite. 206a17

The alternative then remains that the infinite is a potential (dunamei) infinite 206a18.

10.2.3 Aristotle Reassures Mathematicians that His Definition of Infinite Exclusively as Potential Infinite Poses No Poblem for Mathematics Proofs. *Physics* 207b27-34

> Our account does not rob (ouk aphaireitai) the mathematicians of their science, by disproving (anairon) the actual infinite (energeiai apeiron) in the direction of increase, in the sense of the untraversable (adiexiteton).
>
> In point of fact they do not need (oude deontai) the infinite and do not use it (ou chrontai). They postulate only that the finite straight line (peperasmenen) may be produced as far as they wish. 207b27-34

10.3 The Aristotelian Potential Infinite Essentially Coincides with the Platonic Eristic Infinite, and the Platonic Dialectical Already Infinite Essentially Coincides with the Aristotelian Actual Infinite

We will now argue that the two infinities, actual and potential, introduced by Aristotle in *Physics*, are not really new but they are a variation of the two infinities, dialectical, and eristic, respectively, introduced by Plato in the *Philebus* for the identification of the Platonic dialectical infinite, with the Aristotelian *actual infinite*.

10.3.1 The Dialectical Infinite/Already Infinite and the Actual Infinite Are Both Described as Infinites Completed at Some Finite Stage

The Platonic *dialectical infinite* is also described as *already infinite (hede apeiron*, *Philebus* 16e1-2), an expression similar to the expression *actual infinite*, which describes the Aristotelian *completed infinite*.

10.3.2 Dialectical Infinite as Actual Infinite is realized in the Incommensurability Proofs by the Pythagoreans, Theodorus, and Theaetetus, and Eristic Infinite as Potential Infinite in the Incommensurability Proofs by Archytas

A central occurrence of the infinite in Greek Mathematics and philosophy occurs in relation to incommensurability. The infinite described by Plato as *dialectical infinite* and as *already infinite* is clearly the infinite produced in the incommensurability proofs given by the older people that Plato regards as wiser, namely the Pythagoreans, Theodorus, and Theaetetus. The Pythagoreans proved the incommensurability of the diameter to the side of a square, and Theodorus proved the quadratic incommensurabilities of line a to line b, in the cases $a^2 = Nb^2$, with N nonsquare number, $2 < N \leq 17$ (*Theaetetus* 147c-d), both employing the *preservation of Gnomons/application of areas*, the precursor of the Logos Criterion for anthyphairetic periodicity; and, of course, Theaetetus was the first to introduce a theory of ratios for magnitudes, and proved the deep quadratic incommensurabilities with the use of his *Logos Criterion*, another name for the *already infinite*.

Plato criticizes and is ironic toward the later geometers and philosophers who do not employ the Logos Criterion, and go directly to the infinite, but in fact, proceed with less speed.

We can have a good guess whom Plato ironically calls the "now wise," who do not use the dialectic infinite, but the eristic infinite: Archytas, Eudoxus, and their students like Menaichmus, who indeed had no use for the Logos Criterion and the dialectical/aleady infinite. Instead, their basic mathematical results depended heavily on the Principle of the Least (every nonempty subset of the natural numbers has a least element), Archytas for the proof of quadratic and solid incommensurabilities, using the basic Propositions VIII.7 & 8, based on Proposition VII.27 of the *Elements*, itself based on Proposition VII.2 employing the Principle of the Least, and Eudoxus for the proof of the fundamental Proposition V.8, employing directly the Principle of the Least, Archytas and his students had at about that time employed the arithmetic nonanthyphairetic methods, appearing the Books VII and VIII of the Elements of quadratic and solid incommensurabilities by Archytas.

At the same time, Aristotle in *Physics*, a work written not long after the *Philebus*, in the interesting passage 207b27-34, reassures the mathematicians that they do not need *actual infinity* to deal with infinity. Which mathematicians does Aristotle attempt to reassure that rejection of the actual infinite poses no problem for Mathematics? Certainly, not Theaetetus (already dead anyway at that point), who based all his great incommensurability proofs on the Logos Criterion. Aristotle here reassures Archytas, Eudoxus, and their students such as Menaichmus, who were instrumental in turning Mathematics away from anthyphairesis.

An arithmetical proof, based on the Principle of the Least, of incommensurability of, say, the diameter to the side of a square, implies, according to the converse of Proposition X.2 of the Elements, that the anthyphairesis of the diameter to the side is infinite. But, lacking the Logos Criterion, the infinite does not become actual, it is potential. So Plato's eristic is in agreement with Aristotle's potential.

10.3.3 On the One Hand, the Dialectical Infinite Has the Power to Equalize the Opposite Parts and thus Produce an Intelligible Being that Is One and an Intelligible Being with the Power to Generate Numbers with Equalized Units; and, on the Other Hand, the Actual Infinite Is Rejected by Aristotle Exactly Because It Claims to Equalize Opposites that Are Deemed Impossible to Be Equalized, Like the Teacher with the Student and the Medical Doctor with the Patient

The main reason that Plato's dialectic infinite must essentially be identical to Aristotle's actual infinite is the fact that both infinites achieve the crucial *equalization* of opposite parts.

On the one hand, the most prominent property of the *Platonic already infinite*, instituted by the *Logos Criterion* and anthyphairetic periodicity, is the equalization of the two initial opposing elements of the anthyphairetic dyad, in fact, the equalization of all the parts/remainders, generated by the periodic anthyphairesis. This property of *equalization* precisely allows Plato's intelligible Being to be a

(self-similar) One, even though it has been divided into an infinite multitude of parts. It is precisely this equalization that allows Plato to introduce in an intelligible Being the dialectical numbers, the numbers with equalized units.

On the other hand, Aristotle's main argument against *actual infinity* is the fact that equalization is impossible. Does not mention explicitly that the crucial property of the actual infinite is the power to *equalize* the parts, and to generate *dialectical numbers*, but these properties are prominent in Aristotle's argument rejecting the Platonic "self-motion" and Zeno's Dichotomy in the *Physics*, and also in the pseudo-Aristotelian treatise *On Indivisible Lines* rejecting again Zeno's Dichotomy.

For Aristotle, this claimed *equalization* makes no sense, and, as he scathingly notes, it is like equalizing the active teacher with the passive student, who is being taught, or the passive sick person who is being healed with the active medical doctor, who is healing. Thus for Aristotle, the rejection of the actual infinite is equivalent to the rejection of the *equalizing* power of the Logos Criterion, which is the *sine qua non* of Plato's nature of intelligible true Beings, namely, that it has the power to produce equalization of parts, since only equalization effected by periodicity justifies the Oneness of the intelligible Being.

As we will see in more detail in Sect. 11, Aristotle rejects

- in *Physics* 258a Plato's self-moving Soul in the *Phaedrus* 245c–246a, and implicitly Plato's practically identical definition of the intelligible Being in the *Sophist* 247d
- in Physics 263a–b, the second version of Zeno's Dichotomy paradox, in which the infinite multitude of parts produced by the (symbolically dichotomic) division and motion is at the end numbered in a dialectical, equalized manner. Thus equalization is the main feature of both the dialectical infinite and the actual infinite.

11 The Self-Motion of the Soul in Plato's *Phaedrus* 245c5-9 and the Second Version of Zeno's Dichotomy Paradox in Aristotle's *Phaedrus*, Are Each a Dialectical/Actual Infinite (*Physics 257a34-b20* and *263a4-264b9*), a Platonic Intelligible Being, but Nonexistent According to Aristotle

11.1 The Self-Motion of the Soul in Plato's *Phaedrus* 245c5-9 Is a Platonic Intelligible Being, a Dialectical/Actual Infinite, but Nonexistent According to Aristotle's *Physics* 257a34-b20

11.1.1 *For Plato*, Every Motion Is Generated by a Dyad Consisting of the Passive Part that Is Being Moved and the Active Part that Is Causing the Motion. *Timaeus* 57a3-6

Plato in the short but clear *Timaeus* 57a3-6 passage defines Motion as the interaction of an active and a passive part

it is difficult (chalepon), or rather impossible (dunaton),
for *that which is to be moved* (to kinesomenon) to exist without *that which is to move* (tou kinesontos),
or *that which is to move* without *that which is to be moved;*
but in the absence of these, there is no motion (kinesis) *Timaeus* 57e3-6

This description of motion makes motion appear to be close to anthyphairesis. Eudemus' comments given just below go much further in this direction.

11.1.2 The Definition of Soul Using Self-Motion in the *Phaedrus* 245c5-9

Every soul is immortal (athanatos), for that which is ever moving (aeikineton) is immortal but that which moves something (kinoun) else or is moved (kinoumenon) by something else, when it ceases to move, ceases to live.
Only that which moves itself (to auto kinoun), since it does not leave itself, never ceases to move (oupote legei kinoumenon), and this is also the source and beginning of motion for all other things which have motion. *Phaedrus* 245c5-9

11.1.3 *Eudemus's Comments, Reproduced Verbatim by* Simplicius, *Commentary to Aristotle's Physics* 1237,10-21, Reveal that the Nature of Plato's Definition of the Soul in the *Phaedrus* as a Self-Moving Entity Is *Anthyphairetic ("Antanairountes")*

Eudemus divides this too in this way.
"because the moving part [b] is either unmoved or is being moved.
But if the moving part [b] is unmoved, then we have proved what we wanted to prove, namely that the self-moving entity consists of a part being moved [a] and a part that moves and is itself unmoved [b].
But if the moving part [b] moves being itself moved, since everything being moved is moved by something. This part [b] too will be moved by something [a_1].
But this something [a_1] cannot be an external entity, since then it would not be a self-moving entity, but it would be said to be moved by some other part. Hence the moving part [b] will be moved by a part of the self-moving entity, either by one of its parts or by a part of the part that is being moved.
And again, the moving part [a1], moves another part either being itself unmoved, and then it will be the unmoved prime mover, or being itself moved by some part [b_1]; and this moving part will again be a part either by one of its parts or by a part of the part that is being moved.
And thus, *anthyphairating (antanairountes, 1237,21)* in this way, as Eudemus says,
Simplicius, Commentary to Aristotle's Physics 1237, 10-21.
[translation by the author]

Of course, *antanairesis* is another term for *anthyphairesis*; cf. Alexander Aphrodisieus, *Commentary to Aristotle's Topics* 545,16-17.

11.1.4 The Identification of the Self-Moving Soul in the *Phaedrus* with the Intelligible Being in the *Parmenides* and the*Sophist* and with the Dialectical Already Infinite of the *Philebus* 16c5-17a5.

According to Eudemus (Sect. 11.1.3)

(a) "Self-motion" in the *Phaedrus* is interpreted as
  (i) *Motion* in the form of anthyphairetic division of a dyad of opposites, in which
  (ii) The two opposing parts of the dyad are *equalized*; hence we can talk about *self-motion*, presumably by anthyphairetic periodicity and the Logos Criterion.

We realize that the anthyphairetic description of the Soul as self-motion in the *Phaedrus* makes Plato's definition of the Soul identical with

(b) The One of the second hypothesis in the *Parmenides*, the paradigmatical intelligible Being, forming the anthyphairetic dyad One Being, as analyzed in Negrepontis (2024), and

(c) The intelligible true Being, as defined in the *Sophist* 247d8-e4, 257b6-8, forming the anthyphairetic dyad Being, not-Being.

Furthermore, the equalizing power of the intelligible Being in (b) or in (c), in consequence of anthyphairetic periodicity and the "plus one rule" of the *Parmenides* 148d-149d, allows for the generation of dialectical numbers within the intelligible Being, so that, each of the entities (a), (b), (c) is equivalent to

(d) The *dialectical, already infinite* in the *Philebus 16c5-17a5*.

11.1.5 Aristotle's Rejection in *Physics* 257a34-b20 of Plato's Self-Moving Soul, on the Ground that Equalization of Parts Is Impossible (*Physics* 202a21-b22, above) Can Be Extended, by Sect. 11.1.4, to the Rejection of Plato's Intelligible Being, on the Ground that It Is an Actual/Dialectic Infinite, Satisfying the Logos Criterion

In *Physics* 202a21-b22, Aristotle rejects the possibility of equalizing the opposite parts of a dyad, of the active element with the passive element, referring repeatedly to the dyad <active teaching, and passive learning>, and concluding that it is absurd (atopon), impossible (adunaton), without Logos (alogon), these two actions to be equalized. Since equalization of parts is crucial for the One and Many properties of an intelligible Being, it is clear that Aristotle aims his criticism against the nature of Plato's intelligible Being.

This correlation becomes explicit later, in the *Physics* 257a34-b20, where Aristotle employs the earlier passage 202a21-b22 to show that self-motion is impossible, namely the equalization of the active moving part with the passive being moved part of the dyad of motion is impossible, namely exactly because the *actual infinite is rejected as impossible*. But, in Platonic philosophy, these active and passive parts *are* equalized, achieving self-motion, by the Logos Criterion, forming an *already infinite*. So Aristotle's rejection of the actual infinite is in fact rejection of the Platonic already infinite (as noted in Sect. 10.3.3).

The completion of the Eudemus passage, reported by Simplicius, in his *Commentary to Aristotle's Physics* 1237, 21-26 (appearing in Sect. 11.1.3), with the rejection of Plato's definition, in 1237, 10-21, makes clear that what is being rejected is *the periodic*, and thus necessarily *infinite, anthyphairesis*, namely the dialectic infinite.

"And thus, *anthyphairating (antanairountes, 1237,21*) in this way," as Eudemus says,
"we eventually arrive at the prime mover (to protos kinounta),
Those were such that were not being moved by some, but all by all.
Because *it is not possible that the anthyphairesis (antanairesin, 1237,23) is infinite;*
for they would not be in motion, if there were no first moving
for it is shown that it is impossible that the whole is being moved by the whole.
Hence it is necessary that the first part that is active in motion is causing motion but itself is not in motion."
Simplicius, *Commentary to Aristotle's Physics* 1237, 21-26
[[translation by the author]]

11.2 The Second Version of Zeno's Dichotomy Paradox Is a Dialectical/Actual Infinite (*Physics 263a4-264b9*), Identical with a Platonic Intelligible Being, but Nonexistent According to Aristotle

The *first version* of Zeno's Dichotomy paradox initially given in Aristotle's *Physics* 233a21-33, 239b11-14, and repeated here in 263a11-22, states that the runner traversing a finite line interval must contact, pass through an infinite multitude of points in finite time, an impossible task. Aristotle's solution is that there is *no paradox or impossibility at all* because the runner will have to contact and pass through an, indeed, infinite multitude of (half-)points, but this space infinity is comparable *not* with the finite total time needed to complete the action, which action after all is the transversal of a finite length of distance, but will be done *not* in an infinite time, namely in a time that is divided infinitely many times, exactly as the length is divided infinitely many times. Thus additively, finite length is transversed in finite time, and division-wise, infinite length is transversed in infinite time.

But things are radically different in the *second version* of Zeno's Dichotomy Paradox, in which the runner not only contacts an infinite multitude of intervals but also *numbers the infinite* (apeiron arithmekenai arithmon, 263a9-10), as well.

What is the difference between the first version (involving only an infinite multitude of subintervals) and the second version (involving the *numbering* of the infinite multitude of subintervals) of Zeno's Dichotomy? Aristotle states that this turns out to be a substantially different paradox, that requires a radically new solution,

(a) *The second version of Zeno's Dichotomy Paradox is solved by Aristotle in a way analogous to his solution of the Plato's Definition of the Soul in the Phaedrus.*

Aristotle states that his solution of the second version of Zeno's Dichotomy paradox will be similar to his solution of Plato's definition of the soul, (ton auton tropon apanteteon, 263a4), and thus the second version will be rejected as impossible (adunaton, 263a11) because it has the form of.an actual infinity.

According to the general remarks in Sect. 10.3 and our analysis in Sect. 11.1 of Plato's definition of the Soul, including Eudemus's passage, reported by

Simplicius, that motion is *anthyphairetic*. We expect that the structure of the second version of Zeno's Dichotomy Paradox is that of periodic anthyphairesis.

But how can we be convinced that the second version of Zeno's Dichotomy Paradox describes with its numbered divisions an infinite periodic anthyphairesis?

(b) *The condition that when the runner reaches the end will have numbered the infinites suggests equalization of the parts generated by the Division, hence actual infinite.*

The *numbering* of the subintervals is possible ONLY if the subintervals are acceptable units for *dialectic number*, but a dialectic number is possible ONLY if these units/subintervals are *equalized*; but as we have seen in the second hypothesis of the *Parmenides* and the *Sophist*, the subintervals will be equalized ONLY if the *Logos Criterion* holds, namely, as we have seen if we have an *already infinite* (in the sense of *Philebus* 16c5-17a5), and thus an *Aristotelian actual infinite*.

If we want to have a numbering of the infinite, with dialectical numbers, namely with equalization of the units, then, as just explained, the infinite must be aristotelianly actual (entelecheiai)/ /platonically dialectic. Indeed, the numbering of the infinite is associated with the actual, not the potential, infinite; cf. Simplicius, *Commentary to Aristotle's Physics* 1290, 23-24, 28-32, 35-37, 1291,5-7.

(c) *The existence of contrary motions in pairs strongly suggests a motion based on anthyphairesis*.

The usual *continuous* way of dividing an interval into repeated halves does produce an infinite multitude of subintervals, and in fact constitutes *the first form of Zeno's Dichotomy Paradox*, but this infinite is Aristotelianly potential (dunamei)/platonically eristic, and thus with no equalization and no numbering.

On the contrary, the motion in a straight line that results in a completed, actual infinite is NOT a continuous motion, as traditionally thought for the motion of Zeno's Dichotomy paradox, BUT a discontinuous one, in successive steps, so that immediately after a step in straight motion there is a *contrary* (enantia) one in the opposite direction, during which contrary motion there is rest in the straight direction (antikeimene heremia, ?) (264a7-b9).

(d) *The structure of the second version of Zeno's Dichotomy Paradox is identical to the structure of the Divisions of the Sophist, which have been shown to be based on periodic anthyphairesis.*

The divisions in the *Sophist* (of the Angler, the Noble Sophistry in Sect. 2.1, the Sophist) have been shown to have the structure of *anthyphairetic division plus the Logos Criterion* (Negrepontis 2012). Each of these divisions has exactly the same structure as the second version of Zeno's Dichotomy argument, namely

(i) An anthyphairetic division, but in abbreviated, continuous form, mentioning only the first, the third,. . ., in general, the odd stage of the anthyphairesis

(ii) Moreover a periodic one, satisfying the Logos Criterion, hence having the power to equalize the parts generated by the division, a fact indicated by its description as a *Dichotomy*

We conclude that Zeno's true Being is essentially identical to Plato's intelligible being and with the indivisible line.

12 The Application of Zeno's Basic Argument, as Interpreted in Negrepontis (2023a), Is Employed, in the Pseudo-Aristotelian Work *On Indivisible Lines* 968a18-b4, with the Almost Contradictory Property of the Second Version of Zeno's Dichotomy Paradox, of Not Only Touching but Numbering the Infinites as Well, Shows that Zeno's True Being Coincides with the Indivisible Line (Atomos Gramme, 968b4), Hence, According to Sects. 2, 3, 4, 5, 6, 7, 8 and 9 Above, with Plato's Intelligible Being

12.1 The Pseudo-Aristotelian Passage *On Indivisible Lines* 968a18-b4

> Again, according to the argument of Zeno [5] there must be some *partless magnitude (megethos ameres*, 968a19*)*,
> since
> [4] it is impossible to contact an *infinite multitude* (apeiron hapsasthai, 968a20)
> [Hett's rendering: number] in a finite time,
> [3] when contacting each of them, and that which moves must first reach half-way, and half clearly belongs to that which is not without parts (tou de me amerous).
> But if *anything moving along a line* (to epi tes grammes pheromenon) contacts an *infinite multitude* (haptetai ton apeiron, 968a23) [Hett's rendering: series] in a finite time,
> secondly if the faster it travels the greater the space it covers in the same time, and
> [2*] lastly, if the intelligible motion (dianoias kinesis, 968a25-26) is the quickest motion,
> [2] then even intelligible thought (dianoia) must contact an *infinite multitude* (ton apeiron ephaptoito, 968a28) [Hett's rendering: series] one by one in a finite time.
> If, then, intelligible thought (dianoian) contacting the parts one by one is *numbering (arithmein, 968b2)* [Hett's rendering: counting], then
> [1, 3] it must be possible *to number (arithmein, 968b2)* [Hett's rendering: count] *the infinites* (ta apeira, 968b3) [Hett's rendering: series] in finite time.
> [4] If this is *impossible (adunaton, 968,b3)*,
> [5] then there must exist an *indivisible line (atomos gramme, 968b4*).

[[Aristotle, *Minor Works (On Colors, On Things Heard, Physiognomics, On Plants, On Marvellous Things Heard, Mechanical Problems, On Indivisible Lines, Situations and Names of Winds, On Melissus, Xenophanes, and Gorgias)*, translation by W. S. Hett, The Loeb Classical Library, Cambridge Massachusetts, Harvard University Press, London, William Heinemann, 1936. With modifications by the author]]

The passage is about the second (and more essential than the first) version of Zeno's Dichotomy Paradox, as described in Aristotle's *Physics* 263a-b (The first version of Zeno's Dichotomy Paradox, described in Aristotle's *Physics* 233a, 239b, is, as Aristotle correctly points out, nonparadoxical).

12.2 An Outline of Our Anthyphairetic Interpretation of the Pseudo-Aristotelian Passage *On Indivisible Lines* 968a18-b4 as a Special Case of Zeno's Basic Argument

We will analyze this passage, based on our anthyphairetic interpretation of Zeno's Basic Argument in Negrepontis (2023a) in five steps, according to the numbering in brackets that we have added.

The first step in Zeno's Basic Argument is

[1]. The real Being coincides with a sensible Being.

This step is not explicit in the pseudo-Aristotelian passage on indivisible lines, but it is clearly implied at the point marked as [1,3] in the passage in Sect. 12.1, where the sensible property of contacting/passing through an infinite multitude of successive midpoints in finite time is turned into the "intelligible" property of numbering the infinites in finite time.

The second step in Zeno's Basic Argument is the introduction of an almost contradictory property satisfied by the true Beings; in this case

[2]. The Real Being possesses the almost contradictory property [P] of numbering the infinites while passing through them.

The third step consists in transferring property [P] from the true Being to the sensible, on account of [1]. Thus

[3]. A sensible entity must satisfy property [P], namely to have the power to number the infinites when it completes the motion from a point A to a point B.

The fourth step consists in noting, as a consequence of our common sensible experience, and definitely NOT as a logical contradiction, that

[4]. It is impossible that property [P] holds for the sensibles.

The fifth step in Zeno's Basic Argument consists in deducing that

[5]. There is a true Being separate from the sensible entities; and thus, given our two arguments (a) identifying Zeno's true Being with Plato's true Being in Negrepontis (2023a), and (b) identifying Plato's true Being with the Indivisible line in Sects. 2, 3, 4, 5, 6, 7 and 8 in the present chapter, [5] there is an *indivisible line* (*atomos gramme*, 968b3), as claimed in the pseudo-Aristotelian passage.

12.3 Of Interest Are Two Sentences Appearing in the Passage

partless magnitude (megethos ameres, 968a19*)*

is the property of Zeno's true Being, stated in Zeno's Fragment B1, according to which a true Being has an infinite multitude of parts, each with magnitude, and at the same time is measureless. The property is a precursor of the fundamental property One and Many of Plato's intelligible Being. In the above pseudo-Aristotelian passage, it serves as a property essentially equivalent to the property of Being an indivisible line; and indeed both are transfers of the anthyphairetic periodicity to the parts generated by the division, using the plus one rule.

[2*] lastly, if the intelligible motion (dianoias kinesis, 968a25-26) is the quickest motion

This seems an ironic reference to the fact that intelligible, dialectic motion becomes already infinite at some finite stage, achieving, with an incredibly "quickest motion," actual infinity, an impossibility for Aristotle.

13 Conclusion for Sections 10, 11, and 12

We conclude that the second version of Zeno's Dichotomy Paradox, Zeno's true Being, is described, by Aristotle in *Physics*, as an intelligible Plato's true Being (Sects. 10 and 11), and by the pseudo-Aristotelian work *On Indivisible Lines*, as an indivisible line (Sect. 12), confirming the conclusions of both Sects. 2, 3, 4, 5, 6, 7, 8 and 9 of this work that Plato's intelligible Being is an indivisible line, and our interpretation of Zeno's Paradoxes and Arguments in Negrepontis (2023a) that Zeno's true Being coincides with Plato's intelligible true Being.

Acknowledgments I express my warm thanks to Athanase Papadopoulos for encouragement and extensive and essential discussions that have led to an essential improvement of this work.

Abstract

It is argued that Brouwer's philosophy of mathematics makes perfect sense if viewed from an *Eastern* philosophical perspective, as a mathematics in what Erich Fromm called "the being mode of existence." The difficulty Western philosophers have accepting its validity under Brouwer's own justifications is that mathematics is one of the highest prized treasures of Western philosophy (those footnotes to Plato's dialogues).

1 Introduction

L. E. J. Brouwer and *his* intuitionism is perhaps unique in the annals of the history of mathematics and its philosophy by the quality of the hostility encountered from mathematicians and philosophers alike, from his own time all the way to the present day. Brouwer appears to be unique by the unusual fact of the absence of restraint in the verbal abuse, ridicule, and belittling of his philosophy even from mathematicians who have been attracted to intuitionistic mathematics *sans* underlying philosophy.

Craig Smoryński, a mathematical logician, relates in Smoryński (1994) that "some years ago my topology teacher told the class that Brouwer had been a competent topologist who went off the deep end and invented intuitionism" and that "Brouwer is still widely believed to have been a Nazi, and indeed the pre-publication version of one major obituary of him reported that Brouwer had joined the SA and marched in its parades, his hair flowing majestically in the wind."

The latter part of this slanderous piece of disinformation came from a draft of Kreisel and Newman (1969). There is no drop of truth in it. Brouwer never had any kind of sympathies for any nationalist movement, to say nothing of a biologically driven one, as anyone reading (Van Dalen 2013) will learn. It just fits well into the simplistic picture of the world painted by ideologists to claim that counter-modernists (see below) are right-wingers. After sending that draft to Arend Heyting, and receiving the following reply on March 15, 1969 (copy in Heyting Papers, Haarlem; unpublished, courtesy of Mark van Atten), Kreisel removed, thanking Heyting, that passage:

> It is not true that Brouwer supported National-Socialism. I have very good reasons to say this emphatically. Brouwer was a friend of my wife's father, who was a fervent anti-national-socialist. (He was the conductor of the Residentie-orkest, the philharmonic orchestra of The Hague, and he got into trouble by refusing to let the orchestra play the Horst Wessellied in honour of Prince Bernhard, who then, bethroted to Princess Juliana, was still a German subject.) If Brouwer had in the least supported National-Socialism, my wife's father would have broken all links with him, and my wife would have known that.

By 1994, Smoryński had considerably softened his view on Brouwer and pointed out that the above were misrepresentations and that the author of the book he was reviewing had "done a hatchet job on Brouwer" that "van Stigt's psychological analysis of Brouwer is excessive and excessively negative."

In 1977, his take on Brouwer had been more negative, for he had written that (Smoryński 1977, p. 822):

> L.E.J. Brouwer was making the rounds in a bizarre attempt to turn mathematics into a religion. When, in 1920, Hermann Weyl fell prey to Brouwer's lunacy, David Hilbert decided to intervene.

Charles McCarty, an expert on intuitionistic logic, found Brouwer's philosophy to be an "idiosyncratic idealism" (McCarty 2008, p. 39) and argued as follows that one

ought to found intuitionism on philosophical assumptions that bear no resemblance to Brouwer's own (McCarty 1987, p. 542).

> Now, we seem to be left with only one alternative: that constructions are themselves phenomenal objects akin to pains and afterimages. Their intrinsic properties are only those which they seem to have and these are solipsistic: unshared, unsharable and, on some outlooks, incommunicable. As is well known, Brouwer encouraged just this sort of mathematical solipsism. He declared intuitionistic mathematics to be the record of the fruits of the creative activity of a single individual. Constructions are phenomenal objects which, in the mind of the mathematician, make up a kind of Lego set, pieces of which can be assembled and displayed on the inner visual field. Ultimately, the facts of mathematics are just those which he can put together from his fundamental elements.
>
> It is clear that we ought not to follow Brouwer.

We will see later that "single individual," "solipsistic," and "mathematical solipsism" are misunderstandings of a superficial reading of Brouwer's writings.

And Giovanni Sambin, a constructivist mathematician, tells us (Sambin 2008, p. 301):

> We are here to celebrate a master, namely L.E.J. Brouwer, and one hundred years from the birth of his intuitionism. I believe that the best way to keep Brouwer alive is to try and go beyond Brouwer himself. [. . .] To go beyond Brouwer means to learn his lesson, but also try to fix his mistakes and to soften (in ourselves) some hardness in his personality. And in this way to keep him alive. To confine Brouwer into the prison of what he has materially written, would mean to kill him (again).

The philosopher Carl Posy, who devotes a book to mathematical intuitionism (Posy 2020), asks in Posy (1998, p. 308), ironically:

> First, suppose, as I have argued, that Brouwer's position is primarily mathematical. Why does he encumber it with this bugaboo about language in general and about Hilbert's concentration on formal language in particular?

And Georg Kreisel, a mathematical logician who contributed to intuitionistic logic, has mostly derogatory things to say about Brouwer, for example:

> Gödel was utterly bored by Brouwer unlike several logicians and mathematicians who, being dry themselves, were buoyed by Brouwer's probably genuine exuberance. (Kreisel 1987, p. 146)
>
> Apparently, he [Brouwer] did not like to be interrupted anyway; fittingly, for a good solipsist. (Kreisel 1987, p. 147)

With little knowledge of the actual biographical facts that led to the pause in Brouwer's publications, which were not available at that time, Kreisel proposes an entirely implausible explanation, if one takes Brouwer's own philosophical writings seriously (which Kreisel obviously does not, and makes his disdain explicit in Kreisel (1977)):

> Be that as it may, it is a fact that Brouwer himself devoted the ten years after publication of the papers by Heyting and Gödel to non-scientific activities, although, objectively, these papers concerned essential points of his life's work – and although he was only fifty and in good health. It does not seem unreasonable to suppose that he had received an intellectual shock. (Kreisel and Newman 1969, p. 45)
>
> Gödel's immensely natural proofs did not need anything like the heavy distinctions which Brouwer thought essential to his development of constructive mathematics (nor, incidentally, the ingenious constructions that Hilbert had introduced into proof theory). What they did involve was a clear perception of aims and principles, a philosophical, non-doctrinaire analysis, alien to the logical activists of the time. Seeing the incomparable superiority of this kind of analysis Brouwer had to face the question, consciously or unconsciously, to what extent he had even begun to master his own logical ideas. (Kreisel and Newman 1969, p. 44)

The absurdity of Brouwer mastering "his own logical ideas" and the supposed Gödel-envy in Brouwer will become apparent when we get to know Brouwer's views on logic. That Heyting's formalization of intuitionistic logic caused an "intellectual shock" is ludicrous but very much in line with the tone one felt free to use whenever the subject of discussion was Brouwer.

A historian of mathematics found the need to chip in as well while reviewing Van Dalen (1999b): "Part of the mystique around Brouwer is caused by the notorious obscurity (one could say incoherence) of this philosophy. (Grattan-Guinness 1999, p. 529) "Arend Heyting [. . .] became a major protagonist of intuitionism without the supernatural." (Grattan-Guinness 1999, p. 531)

In addition to these squarely hostile remarks about Brouwer's philosophy of mathematics, there is a subtler way of rejecting his philosophy while trying to find firm foundations for a highly valued intuitionistic mathematics by ignoring Brouwer altogether, the way Michael Dummett, a philosopher, did in Dummett (1975) and Dummett (2000).

This is all the more remarkable, given the achievement of the man whose philosophical thought has inspired so little respect in the mathematical and philosophical world. As Gerrit Mannoury summarized one of Brouwer's achievements, in the retelling of Dirk van Dalen (Van Dalen 2013, p. 747):

> In 1947 it was forty years ago that Brouwer got his doctorate. Friends, students and colleagues who had not deserted the old master, organised a jubilee symposium on 19 February. The ceremony took place in the lecture hall of the Geological Institute of Brouwer's brother Aldert. Mannoury addressed his famous student and colleague; he sketched how Bolyai, Riemann and Peirce had broken the hegemony of the Euclidean and Archimedean axioms, how Einstein had 'widened the visual field of physical science', but how Aristotelian logic had survived all disturbances until Brouwer 'emancipated human thought from the authority of the logical principles and so ran down that stronghold itself'.

Sure, the discovery of non-Euclidean geometry had not been greeted with enthusiasm either. But 100 years after its discovery, all doubts regarding its validity and significance had vanished. Why, with many more professional mathematicians and philosophers interested in mathematics active in the twentieth and twenty-first centuries, did the passing of time not similarly validate Brouwer's revolutionary

achievement? It had never attracted more than a handful of devotees and survived into the twenty-first century only in the form of a formal logical theory, far removed from Brouwer's own conception of what intuitionist mathematics ought to be. In the words of Meister Eckhart, who was dear to Brouwer, his intuitionistic mathematics was a work connected with him, which vanished with him.

> For as soon as the work is accomplished, it has instantly vanished, as has the time in which it happened and there is nothing left to do with the work. Should it somehow continue to act, then it must do so with other works and also in another time. (Trans. V. P.)
>
> [Denn sobald das Werk war, ist es sogleich zunichte geworden, ebenso die Zeit, in der es geschah, und ist nun mit dem Werke nichts mehr zu tun. Soll es irgendwie weiter wirken, so muss es mit anderen Werken geschehen und auch in einer anderen Zeit.]. (Eckhart 1934, p. 204)

The task that we set for ourselves is to find out the deep reasons for the rejection of Brouwer's intuitionistic mathematics and of his philosophy of mathematics. We refer to the *deep* reasons to distinguish them from reasons connected with his biography, with Hilbert's animosity and inability to withstand professional criticism, which we take to be *superficial* in the sense that, even in their absence, rejection would have occurred.

We could not find any such explanation in the literature on Brouwer's philosophy, which contains works in which Brouwer's intuitionism is taken seriously and is treated with utmost respect. The literature that takes Brouwer seriously tries to establish links between his philosophy and that of other figures in the history of philosophy. The first such attempt is due to Oskar Becker who found in Becker (1927) that Brouwer's intellectual predecessors were Aristotle, Descartes, and Kant and who understands Brouwer's intuitionism through the prism of a thoroughly *verheideggert* phenomenology. Similarities between Brouwer's philosophy and the *Lebensphilosophie* of the 1920s, as well as with Bergson (which is also emphasized in Largeault (1993)), were put forward in Hesseling (2003). Parallels with Husserl (*sans* Heidegger) are the subject of Van Atten (2007), van Atten (2015, pp. 237–281) (where "a close intellectual kinship between [Husserl and Brouwer]" is detected), and Tieszen (2008). We find these analyses very interesting, yet their aim is to bring Brouwer closer to some sort of Western philosophical mainstream and thus do not aim to explain the historical phenomenon of exclusion and derision of Brouwer's philosophy. Aristotle, Descartes, Kant, and Husserl are pillars of Western philosophy, and hardly anyone dares to write about them in the style sampled above for Brouwer's philosophy. Bergson and the *Lebensphilosophie* had their decades of glory. Moreover, Husserl was a close friend of Hilbert, and their philosophies of mathematics, despite differences, "share a 'mathematics first,' non-revisionist approach toward mathematics" (Hartimo 2017, p. 245). Was the *Grundlagenstreit* between Hilbert and Brouwer, as Heyting would have it (as reported in Van Dalen (2013, p. 829)), only "a historical accident, a blatant failure of common sense and of communication"? Would a mediation by Husserl – who wrote in a letter of May 9, 1928, to Heidegger that "the most interesting in Amsterdam were the long conversations with Brouwer, who made a very important impression on me, one of

a thoroughly original, radically sincere, genuine, very modern man" ["das Interessanteste waren in Amsterdam die langen Gespräche mit Brouwer, der einen ganz bedeutenden Eindruck auf mich machte, den eines völlig originellen, radikal aufrichtigen, echten, ganz modernen Menschen" (Husserl 1994, p. 156)] – have avoided its outcome? Such a mediation could have certainly helped with raising the level of civility that Hilbert was lacking, but we will argue that the *deeper* reasons for rejecting Brouwer's philosophy were not of a nature that could be mediated away. Schopenhauer as a possible influence is dealt with in Eggenberger (1976), Largeault (1993), Detlefsen (1998), Koetsier (2005), and, in-depth, Van Belle (2021). Largeault also finds that

> Another feature that relates Schopenhauer to Brouwer: the discredit that struck their work. Should we believe that each type of culture has its own incompatibilities? [Trans. V. P.]
>
> [Autre trait qui apparente Schopenhauer et Brouwer: le discrédit qui a frappé leur œuvre. Faut-il croire que chaque type de culture comporte ses incompatibilités propres?]. (Largeault 1993, p. 166)

Could a similarity with Schopenhauer – which is entirely hypothetical, as Brouwer mentions very few Western philosophers, and, from those of times past, only Kant and Spinoza – explain the outsider status of his philosophy and the animosity it elicits? Schopenhauer's influence in his lifetime and long past his death has been considerable. His philosophy influenced in the nineteenth century some late Romantics (such as Eminescu), Tolstoy, and philosophers (such as Nietzsche) and in the twentieth century Wittgenstein and Cioran, psychologists (such as Freud and Jung), writers and poets (such as Thomas Mann, Hermann Hesse, Samuel Beckett, Jorge Louis Borges, and Rainer Maria Rilke), and even physicists (such as Einstein or Wolfgang Pauli). Nothing remotely similar can be said about Brouwer's philosophy. One should also consider that Brouwer himself refers to a proximity to "perennial philosophy" (Brouwer 1948, p. 487), not to some *dernier cri* in philosophy.

However, we hold onto the observation that "each type of culture has its own incompatibilities" as a particularly insightful remark.

One may think, with Herbert Mehrtens, that Brouwer's philosophy of mathematics and his intuitionism were doomed by being *counter-modernist.* What this means is spelled out succinctly in Mehrtens (1996, pp. 521, 522) (the long version can be found in Mehrtens (1990)):

> The two common traits of the various modernisms that I identify as central are, first, the autonomy of cultural production and, second, the departure from the vision of an immediate representation of the world of experience. The artist, the composer or the scientist define what is good and true in their respective fields, and they define it autonomously, independently of political, religious, or philosophical authority, and largely not only independently from but against the beliefs dictated by common sense.
>
> [. . .]
>
> The counter-modernist attitude arises with modernism. It is part of modernity, of the modern world. That is why I chose the term counter-modernism instead of anti-modernism. It is the counterpart to modernism, insisting on the question whether there is not some natural

> substance to the truth and meaning of mathematics. The counter-modernist attitude claims that there is such substance, mostly called 'intuition'.

However, counter-modernism, on its own, does not doom a philosopher's posterity, as Gottlob Frege's posthumous destiny clearly shows. Frege was not only counter-modern, he failed to even understand what Hilbert was doing, as his correspondence with Hilbert on the latter's *Grundlagen der Geometrie* of 1899 and his outlandish polemic in the pages of the *Jahresbericht der Deutschen Mathematiker-Vereinigung* clearly shows. Frege was not only counter-modern by insisting that axioms ought to be *true* (in an absolute way), and not arbitrarily chosen, and by his rejection of non-Euclidean geometry at a time when the issue had been long resolved among mathematicians (see Tóth 2009), but he was also a nationalist (Mehrtens suggests (Mehrtens 1996, p. 520) that there is a correlation between anti-modernism and nationalism, although he acknowledges the existence of exceptions, such as Hermann Weyl; Brouwer is falsely depicted as an anti-internationalist, which anyone reading (Van Dalen 2013) will conclude is flatly wrong) and held anti-Semitic views. Although ignored during his lifetime, causing him to adopt a strident polemic and satiric writing style in several publications (see Wille 2020a, b), Frege has enjoyed a posterity as the founding figure of the dominant style of philosophy in the Anglo-Saxon world, analytic philosophy. His writings have generated a veritable exegetical Frege industry, in which even attempts to find how he could have been right in the dispute with Hilbert abound (to the disbelief of mathematicians, such as Hans Freudenthal, who wrote already in 1960 that "Frege, rebuking Hilbert like a schoolboy, also joins the Bœotians. (I have never understood why he is so highly esteemed today.)" (Freudenthal 1962, p. 618)).

A major aspect of modernism is a marked relativism regarding truth claims. Truth is generated either individually or by groups as deemed convenient and almost anything goes. There are no universal truths that can be discerned from the human condition, whose very characteristics are considered debatable, to say nothing of an ability to "discern." Contrary claims are considered oppressive. In the field of logic, for instance, this is expressed by Carnap's principle of tolerance (*Toleranzprinzip*):

> *In logic, there are no morals.* Everyone is at liberty to build his own logic, i.e. his own form of language, as he wishes. All that is required of him is that, if he wishes to discuss it, he must state his methods clearly, and give syntactical rules instead of philosophical arguments. (Carnap 1959, § 17)
>
> [In *der Logik gibt es keine Moral.* Jeder mag seine Logik, d. h. seine Sprachform, aufbauen wie er will. Nur muß er, wenn er mit uns diskutieren will, deutlich angeben, wie er es machen will, syntaktische Bestimmungen geben anstatt philosophlscher Erörterungen. (Carnap 1934, § 17)]

In summarizing the results of his study of Brouwer's philosophy, Michael Detlefsen observes how far from the modernist credo Brouwer's understanding of mathematics is (Detlefsen 1998, p. 331):

> He [Brouwer] was a kind of mathematical 'existentialist' in that he sought a conception of mathematical knowledge that makes it basic to our human existence. For this to be so, he believed, mathematical knowledge must be intimately related to our most basic knowledge of ourselves – that is, to that 'existential' awareness that we have of ourselves as willing, acting beings. Such views are, to be sure, extraordinary when viewed in the light cast by the bland and vapid views that have dominated the philosophy of mathematics of the past few decades. They are not, however, for all that, either silly or out of place.

We find that Largeault's remark on incompatibilities related to "culture" and Detlefsen's remark on the closeness of mathematical knowledge to our human existence, to our *being*, come very close to the two reasons we will put forward for the rejection of Brouwer's philosophy.

The first reason, somewhat similar to that mentioned by Largeault, is connected with the geography of the mind, along the lines of Holenstein (2004), with a mistake made by Central Casting, which placed L. E. J. Brouwer in Europe rather than in "the East" and in mathematics rather than in the humanities. The basics of the characteristic features of thought East and West are taken from Haas (1956) and will be summarized below. We are fully aware that speaking of East and West is not well taken these days, but given that we know only of ideological concerns related to that geography, we will ignore the prohibition to refer to those cardinal points.

The second reason is connected with what Erich Fromm called "the being mode of existence" in Fromm (1976), for we claim that both the philosophy and the mathematics Brouwer envisioned are reflections of a mind in the being mode of existence, and his reason for rejecting classical mathematics and formalism is that he sees them tainted with the having mode of existence.

Given the dominance of Greek philosophy in Western philosophy and mathematics (for, as Whitehead noted "The safest general characterization of the European philosophical tradition is that it consists of a series of footnotes to Plato" (Whitehead 1979, p. 39)) and of the having mode of existence in society, a philosophy and a proposal for a reform in mathematics that go against these two pillars were doomed to fail. Making sense of the connection of the two reasons mentioned above with Brouwer's philosophy and pointing out why that Trojan horse cannot be accepted in the proudest citadel of Western thought, which is mathematics, are, in essence, the aims of this essay.

2 A Very Short Introduction to L. E. J. Brouwer's Life

Luitzen Egbertus Jan Brouwer was born on February 27, 1881, at Overschie, the Netherlands, the first child of a schoolmaster and his wife. He enrolled at the University of Amsterdam as a 16-year-old, passing his final examination in 1904, the year he also got married to Lize de Holl (after being engaged to her since 1902), 11 years his senior, who had a daughter from a previous marriage. His close friends during that time were poets, not mathematicians: Carel Adema van Scheltema, Jan Lockhorst, and Albert Plasschaert. He went three times, on foot, to Italy and back.

The experience as a mathematics student left him wondering whether mathematics would be the field to pursue, whether it would have a life significance.

> As happens so often, I began my academic studies as it were, with a leap in the dark. After two or three years, however full of admiration for my teachers, I still could see the figure of the mathematician only as a servant of natural science or as a collector of truths: – truths fascinating by their immovability, but horrifying by their lifelessness, like stones from barren mountains of disconsolate infinity. And as far as I could see there was room in the mathematical field for talent and devotion, but not for vocation and inspiration. (Brouwer 1946a, p. 474)

The lectures of Gerrit Mannoury, a self-taught mathematician, solidified his interest for mathematics, as he no longer felt in front of a lifeless discipline but rather one intimately connected to life:

> [. . .] The undertone of Mannoury's argument had not whispered: 'Behold, some new acquisitions for our museum of immovable truths', but something like this: Look what I have built for you out of the structured elements of our thinking. – These are the harmonies I desired to realize.[. . .] Behold the harmonies, neither desired nor surmised, which after the completion [of the construction] surprised and delighted me'. (Brouwer 1946b, p. 475)

In a letter written on September 7, 1906, to Adama van Scheltema, Brouwer gives voice to his feelings of estrangement:

> Life is a magic garden. With wondrous, softly shining flowers, but among the flowers the gnomes are walking, and I am so afraid of them. They stand on their head and the worst is that they call out to me that I must also stand on my head; once in a while I try to do so and die with shame; but then sometimes the gnomes cry that I do it very well, and that I am indeed a real gnome too. But on no account will I fall for that. (Van Dalen 2013, p. 196)

He got his doctorate in 1907 with a thesis on both foundational topics and Hilbert's fifth problem. He was appointed a *privaatdocent* at the University of Amsterdam in 1909. In 1912 he was appointed extraordinary professor at that same university and, a year later, ordinary professor on the chair that had been vacated for him by his doctoral advisor Korteweg. He turned down full professorships from Göttingen and Berlin ("I feel far too much a Dutchman and in particular a Friesian Dutchman. And I would rather live here between Dutch friends to enjoy, and Dutch enemies to see through, than far away among strangers!" (Van Dalen 2013, p. 191), from an interview from Wiessing (1960)). Between 1909 and 1913, he published a series of papers that revolutionized topology. One of the results is Brouwer's fixed-point theorem: A continuous map f: $D \to D$, where D is the n-dimensional closed disk, has a fixed point, i.e., there exists an $x_0 \in D$, such that $f(x_0) = x_0$. After 1913, the only major contribution to topology is in 1939, an intuitionistic proof of the triangulation of any differentiable manifold. Starting with 1913, he returned to the subject of his doctoral dissertation: the rebuilding of mathematics on a sound foundation, *intuitionistic mathematics*. Appointed to the editorial board of the leading mathematical journal of the time, the *Mathematische*

Annalen in 1914, at the invitation of Felix Klein, he was removed from that board in 1928 by David Hilbert on fabricated grounds. The editorial board was completely revamped, with Albert Einstein and Constantin Carathéodory, who had resisted Brouwer's removal, removed as well.

Einstein had tried to convince Hilbert that one does not choose one's personality or one's health, regardless of the afflicted organs or systems, and that it is in bad taste to make any fuss about such matters. On October 18, 1928, he wrote to Hilbert

> Mr. Brouwer is an unwilling defender of Lombroso's theory of the close connection between genius and madness. I cannot understand how you can take this man, who in his country not only enjoys the reputation of a great mathematician but also that of a hopeless troublemaker, so bitterly seriously (Trans. V P.)
>
> [. . .]
>
> I consider him [Brouwer], with all due respect for his mind, a psychopath and it is my opinion that it is neither objectively justified nor appropriate to undertake anything against him. I would say: 'Sire, give him the liberty of a jester!' If you cannot bring yourself to this, because his behaviour gets too much on your nerves, for God's sake do what you have to do. I, myself, cannot sign, for the above reasons such a letter. (Van Dalen 2013, p. 556)
>
> [Herr Brouwer ist ein unfreiwilliger Verfechter von Lombrosos Theorie der nahen Verbindung von Genie und Wahnsinn. Ich kann es nicht begreifen, dass Sie diesem Mann, der in seinem Lande neben dem Rufe eines grossen Mathematikers auch den eines hoffnungslosen Querulanten geniesst, so bitter ernst nehmen koennen.
>
> [. . .]
>
> Ich betrachte ihn bei aller Hochachtung vor seinem Geiste als einen Psychopathen und halte es weder fuer objektiv gerechtfertigt noch fuer zweckmaessig etwas gegen ihn zu unternehmen. Ihnen moechte ich sagen:‚Sire, geben Sie ihm Narrenfreiheit'! Wenn Sie dies aber nicht vermoegen, weil sein Verhalten Ihnen zu sehr auf die Nerven gegangen ist, so tun Sie in Gottes Namen, was sie muessen. Ich selbst kann aus besagten Gruenden einen solchen Brief nicht unterzeichnen.]. (Rowe and Felsch 2019, p. 278f)]

A few days later, on October 23, 1928, Einstein complemented the above with a somewhat different evaluation of Brouwer in a letter to Carathéodory:

> Furthermore, I admire him not only as a particularly clairvoyant spirit, but also as a forthright and characterful man. (Trans. V. P.)
>
> [Im uebrigen aber verehre ich ihn nicht nur als ueberaus hellsehenden Geist, sondern auch als geraden und charaktervollen Menschen.]. (Rowe and Felsch 2019, p. 120)

After his removal from the editorial board of the *Mathematische Annalen*, Brouwer worked tirelessly to launch a competing journal with an international editorial board. He became, in 1934, a founding editor of *Compositio Mathematica*, a truly international journal (unlike the *Annalen*, which, even before Brouwer's removal, had only two non-German members on its editorial board) – with all German editors resigning in protest in 1936 due to Brouwer's refusal to purge its Jewish editors – which ceased publication in 1940 due to the German invasion of the Netherlands. When it resumed publication, in 1951, he was removed from the editorial board of his own journal by his colleagues. The effect that episode had on him is expressed in a letter of May 8, 1953, to Mannoury as follows:

> I too have been in bed for months during this winter at a relapse of a heart attack, which I suffered in 1950 being suddenly informed of the theft of my journal and the unbelievable means of deceit and fraud used. It is, I believe, through this event which I on the one hand out of self-preservation must try to forget and to which I can, on the other hand, not resign myself, that I have definitely become misanthropic within our national borders. Remarkable, how little philosophy sometimes protects against psycho-somatic reflexes and reactions. (Van Dalen 2013, p. 789) (Dutch original in Van Dalen (2011b, p. 2789))

In 1918 a group consisting of Brouwer; Frederik Van Eeden, a writer and psychiatrist; Jacob de Haan, a Dutch-Jewish writer; and Gerrit Mannoury, a mathematician, invited many renowned figures, such as Rabindranath Tagore, Martin Buber, Giuseppe Peano, and Henri Borel, a sinologist and journalist, to join it, with the aim of "the creation of new words, which form a code of elementary means of communication for the systematic activity of a new and holier society" (Van Dalen 2013, p. 264). The choice of a sinologist was connected with Brouwer's belief that, unlike Western languages, Eastern languages allow for the expression of a different philosophy (Van Stigt 1990, p. 200).

The International Institute for Philosophy saw its founding that year and was dissolved in 1922 to be replaced by the *Signific Circle*. Buber had declined the invitation, questioning the possibility of a collective creation of words, given that "The creation of a word is for me one of the most mysterious processes of spiritual life" (Van Dalen 2013, p. 262) [Wortschöpfung, Erschaffung des Wortes ist für mich einer der geheimnisvollsten Vorgänge des geistigen Lebens (Van Dalen 2011b, p. 793)].

Brouwer's reply to Buber is of great interest for our thesis of the *Eastern* nature of Brouwer's mindset, as it is one of several places in which he deplores shortcomings in the *Western* cultural setup.

> The word of the Occident does indeed in various cases have in addition to its material, a spiritual value, but the latter is always subjugated to the first, and where the first one has acquired a more certain and permanent orienting influence on the activity of society, in the sense that it induces isolated individuals, in their pursuit of physical security and material comfort, to hinder each other as little as possible and wherever possible to support each other; the latter lacks any influence on the legal state of affairs (except possibly when it is used itself for the devious realisation of injustice); therefore its influences are weak, fleeting and local.
>
> Words which have exclusively a spiritual value and which are suitable for the in- and exhaling of the Weltgeist and for the orientation on the observance of Tao are non-existent in Occidental languages; should they exist, then their influence would be paralysed by the mutual physical hatred, rooted in mutual distrust of the purity of their birth, of people who live too closely together, and which hampers the pursuit of material comfort by the single individual only mildly, but which considerably hampers the in- and exhalation of the Weltgeist. (Van Dalen 2011a, p. 262)
>
> [Das abendländische Wort besitzt zwar in mehreren Fällen neben seinem materiellen einen seelischen Wert, aber letzterer ist immer dem ersteren untergeordnet, und während erstere eine sichere und dauerhaft orientierende Wirkung auf die Aktivität der Gemeinschaft erworben hat, in dem Sinne dass es die einzelnen Individuen dazubringt, im Erstreben körperlicher Sicherheit und materiellen Komforts einander möglichst wenig zu hindern und womöglich zu unterstïutzen, entbehrt letzterer jeden Einflusz auf die Rechtsverhältnisse

(es sei denn insofern er daselbst zur Erschleichung von Unrecht missbraucht wird); demzufolge sind seine Wirkungen schwach, vorübergehend und lokalisiert.

Wörter, welche ausschliesslich seelische Werte besitzen und dazu geeignet sind, die Gemeinschaft auf das Ein- und Ausatmen des Weltgeistes und das Innehalten von Tao hin zu orientieren, gibt es in den abendländischen Sprachen nicht; wenn solche existierten, würde übrigens ihre Wirkung lahmgelegt werden durch den wechselseitigen leiblichen Hass der zu dicht bei einander lebenden Menschen, welcher im gegenseitigen Misstrauen gegen die Reinheit ihrer Geburt wurzelt und das Erstreben materiellen Komforts durch die einzelnen Individuen nur unerheblich, das Ein- und Ausatmen des Weltgeistes aber in hohem Masse hindert. (Van Dalen 2011b, p. 792)]

He expressed himself similarly in 1948:

Eastern devotion has perhaps better expressed this wisdom than any western man could have done. For instance in the following passages of the Bhagavad-Gita which even in translation have conserved their electrifying power. (Brouwer 1948, p. 486)

Another one who declined the invitation to join the project of word creation was Erich Gutkind, the author of a prophetic, mystical book *Siderische Geburt – Seraphische Wanderungen vom Tode der Welt zu Taufe der Tat* (*Sideric birth – Seraphic wanderings from the death of the world to the baptism of the deed*), and a friend of Walter Benjamin und Gershom Scholem. Gutkind "doubted if European languages could simply incorporate or assimilate words of a high spiritual value" (Van Dalen 2013, p. 263) for "words like the Chinese Tao or the Hebrew Torah, so strikingly analogue in meaning and sound, can never be grown on a European foundation and presuppose a radical reform of society, require a higher society" (Van Stigt 1990, p. 200), to which Brouwer replied that "The word cannot wait for the higher form of society, because the higher form of society waits for the word" (Van Dalen 2013, p. 263).

Brouwer became a lifelong friend of Erich and Lucia Gutkind. After Brouwer's first visit of the Gutkinds in Berlin, they wrote to Van Eeden "Brouwer is with us and he will bring you our greetings. We get along wonderfully and we are enormously pleased with him" (Van Dalen 2013, p. 323).

By 1946 Brouwer had come to the conclusion that "Buber was right in his denial of the creative power of collective work in this domain" (Van Stigt 1990, p. 196) of creating a language that would, on the one hand, be "purified of rhetoric, subjective, demagogic and in general of deceptively emotional admixtures" and, on the other hand, contain "words for basic immaterial notions which can serve as elements of a more indicative language, suitable to express general mental values and human emotions of fraternity and solidarity" (Brouwer 1946a, p. 452).

Besides the injustice visited upon him by his removal without any drop of a valid reason from the editorial board of the *Mathematische Annalen*, Brouwer suffered another blow in 1929, which he related in a letter to Hans Hahn of August 9, 1929:

Due to a disturbance in the execution of my travel plan, your letter from Bellagio reached me with a long delay. The disturbance was caused by a great calamity: four days ago my briefcase, which also contained my scientific diary, was stolen from me on the front platform

> of a Brussels tram, by a pickpocket, and both the police and the detectives consider the case as hopeless. Since in this diary my collective scientific thoughts and ideas of the last three years, which have largely disappeared from my memory, and of which only a few have already found a registration elsewhere, had been recorded, this event means for my scientific personality a serious personal mutilation, in a way that is like the decapitation (elimination of the central process) for a pine tree. To my amazement, I remain so far, fairly calm under this blow of fate; I believe, however, from certain phenomena, that I have nonetheless suffered a nervous collapse, the consequences of which will perhaps only later become visible, together with a disorganisation of my scientific thoughts. (Van Dalen 2013, p. 600f)
>
> [Infolge einer Störung in der Abwickelung meines Reiseplanes hat mich Ihr Brief aus Bellagio mit grosser Verzögerung erreicht. Die Störung wurde von einer grossen Kalamität verursacht: vor 4 Tagen wurde mir meine Brieftasche, welche auch mein wissenschaftliches Tagebuch enthielt, auf dem Vorderbalcon der Brüsseler Strassenbahn von Taschendieben gestohlen, und sowohl Polizei wie Detektive betrachten die Angelegenheit als hoffnungslos. Weil in diesem Tagebuch meine sämtlichen wissenschaftlichen Gedanken und Einfälle der letzten drei Jahren archiviert waren, welche grossenteils meinem Gedächtnis entschwunden sind und von denen nur wenige schon anderweitige Festlegung gefunden haben, so bedeutet das Geschehnis für meine wissenschaftliche Persönlichkeit eine schwere Verstümmelung, gewissermassen dasselbe was für eine Tanne die Enthauptung (Entfernung des Zentralsprosses) bedeutet. Zu meiner Verwunderung bleibe ich unter diesem Schicksalsschlag bisher ziemlich ruhig; ich glaube aber nach gewissen Erscheinungen, dass ich trotzdem eine Nervenerschütterung erlitten haben muss, deren Folgen vielleicht erst später, zusammen mit der Desorganisierung meiner wissenschaftlichen Gedankenwelt, ans Licht treten werden. (Van Dalen 2011b, p. 1747)]

Later on, twice, in 1941 and 1944 (Van Dalen 2013, pp. 674, 693), his house was on fire, so that Brouwer would write in a letter to De Loor on June 20, 1945 (Van Dalen 2013, p. 702), that "as a consequence my scientific archive and with it the manuscripts of my unpublished research have been lost." (Van Dalen 2013, p. 702)

If one is looking for the long mathematical silence that ensued, then it is not Gödel's theorems that brought it about, but these events.

Among the seven doctoral students Brouwer had, two developed intuitionistic mathematics further: Maurits Belinfante and Arend Heyting. The former, a Portuguese Jew, Brouwer's first intuitionistic follower, who developed intuitionistic analysis, was deported first to Theresienstadt and then in 1944 to Auschwitz, where he was killed. Heyting wrote, at Brouwer's suggestion, his dissertation on an intuitionistic axiomatic development of projective geometry. Later Heyting developed a formal logical calculus that should capture the essence of intuitionistically valid inferences. Brouwer was "highly pleased" with Heyting's work. However, as related by Heyting, "He [Brouwer] always maintained that formalization is unproductive, a sterile exercise. He never changed his mind about that" (Van Stigt 1990, p. 290). Developments of intuitionistic mathematics after World War II proceeded among formal logic lines.

In the 1930s, he served on the municipal council of Blaricum and was involved in several lawsuits and other time-consuming non-mathematical and unpleasant activities that he felt a compulsion to be involved in out of a very strong sense of justice.

After the war, he was suspended for some months as a suspected collaborationist, reprimanded, and then re-instated by the University. At the end of 1945, Brouwer

contacted his old friend Erich Gutkind, now living in the United States. Gutkind wrote a letter to Einstein, letting him know that Brouwer had expressed a strong wish to emigrate to the United States. He mentioned "that Brouwer had hidden some Jews in his institute and took care of them" as well as that "I recall that Brouwer travelled a couple of times to Germany to get German mathematicians out of German concentration camps" (Van Dalen 2013, p. 716). Gutkind asked Einstein to help Brouwer find a position in the United States. Einstein refused to help Brouwer, given that he was under investigation for collaboration with the occupier.

"There is no doubt that Brouwer suffered under the post-war accusations, – he, one of the leading Dutch scientists, who had always come to the defence of the underdog, was classified as a spineless collaborationist!" (Van Dalen 2013, p. 716).

He published a few more papers, one (Brouwer 1952a) showing that his own fixed-point theorem is intuitionistically false but can be rephrased intuitionistically by stating that, given a natural number n, one can find a point x_0 whose distance to $f(x_0)$ is less than 2^{-n}. He traveled extensively to give lectures on intuitionism. In 1959 his wife Lize died. In 1966, he was run over, crossing the street in front of his house in Blaricum, to deliver some presents for Saint Nicholas' eve to friends across the road, by three cars.

Van Dalen writes that "Somehow he managed to inspire either love and admiration, or hatred and repugnance" (Van Dalen 2013, p. 714). In the first category was the homeopathic physician Ralph Twentyman, who wrote that "the high spiritedness Brouwer brought into any room is one of my most treasured memories. Everything moved up a floor or two when he appeared" (Van Dalen 2013, p. 600f).

We should also add that Brouwer was very far from having adopted the European professorial persona. He could disappear in the middle of a discussion in the garden of his house, with women present, enter his house, and re-appear naked (as he enjoyed nude open-air baths), continuing the previous conversation, with no one commenting (Van Dalen 2013, p. 645). Or, during a visit to Canada, at 72, he would disappear at a picnic to climb a tree (Van Dalen 2013, p. 8f). "When he stayed with [Georg Henrik] von Wright, he asked his host one night, 'would you mind if I slept out on the ground tonight?' Von Wright may have had his doubts about his aged guest, but he saw no reason to refuse the request. And so Brouwer once more was one with nature under the sky, as he loved to be" (Van Dalen 2013, p. 788f).

During an interview with Wiessing, translated from Wiessing (1960, p. 143f) in Van Dalen (2013, p. 190f), Brouwer explained succinctly his intellectual journey:

> Basically my mathematical thinking is non-sensory internal architecture. You may compare these forms of thought to music or poetry. My first inklings of the possibility of such a mathematics emerged, I think, from discussions with my teachers at the time of my HBS [high school] and gymnasium study. But only in my dissertation of 1907 have I started to give these thoughts a definite formulation. Since then this mathematics, nowadays called 'intuitionistic', has developed with interruptions. The recognition in professional circles of this work of mine came only in a rather slow tempo, with many ups and downs. It has by no means found general acceptance! Many view it, even now, as charlatanism. There are also people who say that it may be correct, but that it is totally uninteresting and not even new.

> If I had not, now and then, written about 'ordinary mathematics', I don't think a place at a Dutch University could have been found for me.
>
> [. . .]
>
> [. . .] I don't like mathematics and it basically bores me.
>
> Wiessing: What would you, if it comes to that, rather have done than practice mathematics?
>
> Brouwer: That is hard to say. Let me say: to have no subject and to let my thoughts roam freely. Every attachment to a subject brings, as you will agree, that your realm of thought suffers a certain mutilation. And it is obvious that then one can only have pleasure in such a profession, if one is, as I sometimes observe with some people, supported and driven by ambition or conviction. But that has never been the case with me. Anyhow, life demands that you choose a profession. Well, then I think that science is for a man like me, who is by nature solitary, not such a bad sanctuary. One is less dependent on the public, and one can more easily preserve one's solitude, than if one takes up literature or the visual arts, not to mention music. For no matter how much pleasure and satisfaction art by itself may give to a person, society, I think, demands more violating concessions from artists than science does.

It is worth mentioning that Brouwer, who almost single-handedly developed geometric topology and could have continued on that path to certain glory, decided to return to the concerns of his youth (he had hoped, during his topological years, that his topological work could be made intuitionistically sound (see Dubucs 1988; Johnson 1981), repudiated his topological work, and never lectured on it, although the preoccupation with intuitionism made him appear, in the eyes of many mathematicians, a "charlatan," as he put it. To give a specific example, which also shows that an admiration for the Bhagavad Gita (see Weil 1991) in two European mathematicians can coexist with very different philosophies of mathematics, André Weil attended Brouwer's Berlin lectures on intuitionism and wrote to Fréchet on January 31, 1927, that

> He has declared in his first lecture that the principle of the excluded third is a superstition which is about to disappear. It is a pity that such a remarkable man devotes himself exclusively to such bizarre things. (Van Dalen 2013, p. 595)

Brouwer is one of the very rare cases who not only felt a slight hesitation at the alternative presented in the thought experiment devised by Simone Weil but actually chose to be an object of derision rather than betray the truth. Here is the thought experiment of a manifest counter-modern, one who believed in truth:

> If one were to propose to all those whose profession is to think, priests, pastors, philosophers, writers, scholars, professors of all kinds, the choice, from the present moment on, between two destinies: either to sink immediately and definitively into idiocy, literally, with all the humiliations that such a collapse entails, and keeping only enough lucidity to feel all its bitterness; or a sudden and prodigious development of intellectual faculties, which ensures them an immediate global celebrity and glory after death for millennia, but with the inconvenience that their thought would always stay a little outside of the truth; can one believe that a lot of them would experience for such a choice even a slight hesitation? [Trans. V. P.]
>
> [Si l'on proposait à tous ceux qui ont pour profession de penser, prêtres, pasteurs, philosophes, écrivains, savants, professeurs de toute espèce, le choix, à partir de l'instant

> présent, entre deux destinées: ou sombrer immédiatement et définitivement dans l'idiotie, au sens littéral, avec toutes les humiliations qu'un tel effondrement entraine, et gardant seulement assez de lucidité pour en éprouver toute l'amertume; ou un développement soudain et prodigieux des facultés intellectuelles, qui leur assure une célébrité mondiale immédiate et la gloire après la mort pendant des millénaires, mais avec cet inconvénient que leur pensée séjournerait toujours un peu en dehors de la vérité; peut-on croire que beaucoup d'entre eux éprouveraient pour un tel choix même une légère hésitation?]. (Weil 1949, p. 328)

Needless to say, this very short introduction does not relieve the reader, in particular, the reader who thinks negatively about Brouwer, to consult Van Dalen (2013) or Van Dalen (1999a) and Van Dalen (2005), Van Dalen (2011a), and Van Dalen (2011b) to get whatever picture some footprints on a sandy beach can reveal about a life. Unsurprisingly, both the reviews for *Mathematical Reviews* and for *Zentralblatt für Mathematik* (Dauben 2000; 2007; Soifer 2007) find that Van Dalen was too kind to Brouwer, for they would have seen some facts in a significantly more detrimental light. The much more substantial reviews (Smoryński 2015; Johnson 2014; Kaneko 2002b) are free from that kind of critique. While praising Van Dalen's monumental achievement, Gray (2015, p. 134) finds that "there is a slight feeling of sympathy for Brouwer that the reviewer does not share, being perhaps less enamoured of intuitionism" and that

> there was a solipsistic streak in him that strengthened his inability to get people on his side, that elevated a reasonable but by no means secure philosophical opinion to one of inflexible rectitude, that kept him illiberal and unable to see that his allies were increasingly rightwing in toxic times, and that made him capable of cruelly selfish behaviour. (Gray 2015, p. 134)

Gray is here very selective in the decision regarding who Brouwer's "allies" were, thinking of the National-Socialists Ludwig Bieberbach and Theodor Vahlen, but forgetting his friends with far-left leanings, the communists Henri Wiessing (Van Dalen 2013, p. 281) and Gerrit Mannoury (Van Dalen 2013, p. 513), and devotes significant space in his review to the post-war accusations against Brouwer, which were, to a careful reader of Van Dalen (2013), without any basis in fact, or rather a dispute about the most appropriate resistance strategy. It was by no means clear what that strategy should be, as a reader of Hermans (1949) would come to realize. Equating accusations with guilt would also be ill-advised in an atmosphere in which, even as late as 1963 – not 1945 – Miep Gies would be considered by the police "one of the suspected people" for the betrayal on August 4, 1944, of the Frank family (Gies and Gold 1987, p. 250) on the basis of her having been born in Vienna.

The "illiberal" part is even more mysterious, given that Brouwer was in 1935 and 1939 elected to the council of the town Blaricum, with a significant artist population. What was he advocating for?

> The preservation of the local heath (a nature reserve), [. . .] better access for walkers while keeping out cars [. . .] a raise for the local police [. . .], added improvements to a plan for the construction of a cycle path, [. . .] the improvement of the soccer field. [. . .] When [. . .] the committee of action 'For God' demanded the barring of the periodical of the freethinkers

> from the public library, Brouwer remarked that according to the state's instructions all groups must be represented. (Van Dalen 2013, p. 641)

And do these thoughts sound like those of an "illiberal" person?

> Power over fellow-creatures will be avoided. Firstly because one would get mixed up with limitations of other people's liberty of action. And secondly because those fellow-creatures are part of the reflex image held out to mind from its deepest home, therefore have to be respected, and must not be judged, let alone condemned, despised or rejected, even if they are enemies to be fought against. (Brouwer 1948, p. 486)

If one were to think that van Dalen's biography has cleared the air of the cobwebs of lies that have been spun around Brouwer, one must have forgotten that, as Thomas Francklin wrote:

> Falsehood will fly, as it were, on the wings of the wind, and carry its tales to every corner of the earth; whilst truth lags behind; her steps, though sure, are slow and solemn, and she has neither vigour nor activity enough to pursue and overtake her enemy. (Francklin 1787, Sermon XI (On Vigilance), p. 233)

Defamations, heard through the grapevine, are passed on, regardless of the absence of any mention of anything remotely resembling the accusation in the extensive correspondence related to the *Mathematische Annalen* affair and picked up in AD 2021 in Budianksy (2021, p. 82) (where Brouwer becomes a "committed Aryan nationalist") and Misak (2021) (where Brouwer is mentioned as "a budding Nazi collaborator") as facts, with

> The dispute took on a particular nuance in the sense that the Dutchman Brouwer set himself up as a champion of Aryan Germanness. Consequently Hilbert removed him from the editorial board of the *Mathematische Annalen* after he objected to what he felt were too many Eastern European Jewish ("*Ostjuden*") authors. (Fraenkel 2016, p. 137)

as source.

3 East and West, to Have or to Be

3.1 Haas on the Main Characteristic of the Mind East and West

To substantiate why an approach from an "Eastern" position to mathematics is unacceptable by the philosophical establishment, we need to define what we mean by the distinction between East and West in philosophy. We think that the following quotations from Haas (1956) will give an idea of what is meant by these different fundamental approaches.

> However, the decisive act which constitutes Eastern mind and civilization – the positing or the fixing of the subject – implies the idea that an existence entirely separated from and

independent of the subject cannot be conceived. So what becomes in the Western mind and civilization the autonomous object, is paralleled in the East by the other which is coherent with and held in existence by the subject. (Haas 1956, p. 114)

But there lives on in the world concept and philosophy of the East a definite aversion to those pairs of opposites which dominate the history of Western thought – the living and the inanimate, mind and matter, soul and body, the conscious and the unconscious. And the absence of these antitheses is the expression of the closeness in which the other despite its otherness is held to the subject.[. . .] Being a form of the mind the subjective attitude is not restricted to any field of existence. It is active everywhere [. . .] Its most penetrating consequence is its denial to the external world of an existence in its own right. Such an objective existence, independent of the perception of the subject, seems to the Asiatic mind absurd and paradoxical – a monstrous idea. (Haas 1956, p. 116)

On the other hand, radical idealism with its theory of the illusory character of the external world is not innate in, let alone characteristic of, Asia. It belongs as do so many other extremist theories to the West. (Haas 1956, p. 117)

The East takes opposites as they are immediately experienced from life and nature. Thus while the principle of the contraries is recognized, they are left in their original context and to their original operation. For this reason they have been interpreted by contemplative thought as polarities whose contrariety, which is more apparent than real, conceals a deeper meaning of balance and harmony. (Haas 1956, p. 145)

The structures of the Eastern mind leads it to regard reality as somehow co-ordinated and akin to the subject. The innate tendency is to bridge and diminish the distance between reality and the subject. (Haas 1956, p. 130)

Ignoring the objectifying process of thought, the East dismisses the outer world as the all important object of speculation. Instead it stresses the necessary relationship of the Real with the subject.

This of course, radically changes the position and meaning of the term subject.[. . .] the subject, for the Easterner, is relative not to the object, that is not to an objective world as the essence of reality, but to an entity close to him [. . .]. (Haas 1956, p. 131)

The history of the Western mind in general and of its philosophical thought in particular is characterized by two great conceptions. Neither assumed a prominent role in the East. The one is mathematics – the other the idea of evolution.

Important as the invention and knowledge of mathematics are in China and particularly in India, the East cannot claim anything comparable to the systematic development of mathematical theory and applied mathematics in the West. (Haas 1956, p. 150)

In the history of Western philosophy the importance of mathematical thought on the one hand, and the idea of evolution on the other, is vividly illustrated by the fact that with few exceptions the most important philosophers can be grouped as those who were inspired by mathematical thinking and those who follow the line of the idea of evolution. The first group is represented by men like Pythagoras, Plato, Descartes, Leibniz and Kant while the other can claim the names of Heraclitus, Aristotle and Hegel.

If philosophical mysticism is credited with having vaulted this chasm, it did so at the price of ignoring the structure of the Western mind as well as its premises and aspirations. In this fashion it succeeded in avoiding the issue. It is no mere coincidence that the two outstanding representatives of this are to be found at the periphery of Western civilization – Plotinus, who was born in Egypt and inspired by the currents of Eastern thought, and Spinoza, of Jewish descent. (Haas 1956, p. 151f)

Eastern cognition is interested in consciousness itself. Western cognition is interested in the objects of consciousness. (Haas 1956, p. 167)

In the mind of the East the subject holds the predominant place occupied by the object in the West (Haas 1956, p. 180).

Reduced to its essence Eastern knowledge is a form of being, a state of consciousness, that is lucid and self-sufficient (Haas 1956, p. 182).

> Western knowledge is a form of having (Haas 1956, p. 182).
> At the height of his fulfillment, the man of the East stands utterly alone (Haas 1956, p. 232).

James P. Allen, an Egyptologist, expresses a similar view on the nature of Eastern cognition in (Allen 1988, p. ix):

> We have divorced philosophy, as a discipline, from religion. In the former we appreciate reality *objectively*, as something capable of study; in the latter we understand it *subjectively*, as something that can only be experienced. This dichotomy did not govern ancient Near Eastern thought. To it all appreciation of reality was subjective – "I-Thou" rather than "I-It."

One should not conclude from the above that there is no room in the Eastern mind for forms of realism. The *Nyāya* (one of the six orthodox schools of Hinduism) believed "in the external existence and mind-independence, not just of the ordinary objects of daily experience, but also of the universals or properties which reside in those objects. They combined this 'metaphysical realism' with a correspondingly realist or externalist approach towards cognitive and semantic content" (Ganeri 1996, p. 111f). This is precisely the kind of view repudiated by Brouwer and the Buddha. While several schools of Indian philosophy embrace *ananta* (infinity) – Patañjali recommends meditating on *ananta*, for the Jain "the theory of multiplexity of reality (*anekānta-vāda*) rests on [. . .] the conviction that things relate to each other by an infinite number of relations" (Balcerowicz 2001, p. 379) – both Brouwer and José Ortega y Gasset allow no place for actual infinity in mathematics, the latter, who also rejected the use of the principle of the excluded middle in mathematics, insisting that mathematicians should "focus only on objects that are 'immediately present' for the human intuition" (Rabi 2016, p. 65) and that "the infinite cannot be immediately present for the human intuition" (Rabi 2016, p. 68).

3.2 Fromm on to Have or to Be

Erich Fromm, a radical-humanistic psychoanalyst, has described in Fromm (1976) two basic character orientations, which he calls "the having mode of existence" and "the being mode of existence." The former is the dominant mode of existence in contemporary society. Our claim is that the spirit of Brouwer's philosophy – "the spirit out of which the work takes shape" ["der Geist, aus dem das Werk geschieht" (Eckhart 1934, p. 204)] – is that of the latter. Fromm cites from the works or sayings of Jesus, the Buddha, Meister Eckhart, Spinoza, and Albert Schweitzer, to which he refers as "Masters of Living," to circumscribe the being mode of existence.

Fromm was decidedly counter-modern, for he considered, much like Spinoza – for whom "mental health is, in the last analysis, a manifestation of right living; mental illness, a symptom of the failure to live according to the requirements of human nature" (Fromm 1976, p. 78) – that there exists a "human nature" and wrote about the "pathology of normalcy"; in other words, unlike standard psychiatry, he

found that being adapted to a society that he found insane and acting in its spirit is *not* a sign of sanity. Although he grew up in Frankfurt in the twentieth century, in reality he grew up, as he put it in interviews, in a "medieval atmosphere, in which everything is dedicated to traditional learning" (Friedman 2013, p. 4). Moreover:

> Between 1916 and 1921, Fromm actively studied topics linked to the Hebrew Bible in a small group, led by Rabbi Nehemia Nobel in Frankfurt, that included Martin Buber, Leo Baeck, and Gershom Scholem. (Friedman 2013, p. xxxiii)

Here are a few quotations from Fromm (1976) that refer to themes that occur in Brouwer's philosophy as well.

> Optimum knowledge in the being mode is *to know more deeply.* In the having mode it is *to have more knowledge*. (Fromm 1976, p. 34)
>
> Having refers to *things* and things are fixed and *describable.* Being refers to *experience*, and human experience is in principle not describable. What is fully describable is our *persona* – the mask we each wear, the ego we present – for this persona is in itself a thing. In contrast, the living human being is not a dead image and cannot be described like a thing. In fact, the living human being cannot be described at all. Indeed, much can be said about me, about my character, about my total orientation to life. This insightful knowledge can go very far in understanding and describing my own or another's psychical structure. But the total me, my whole individuality, my suchness that is as unique as my fingerprints are, can never be fully understood, not even by empathy, for no two human beings are entirely alike. Only in the process of mutual alive relatedness can the other and I overcome the barrier of separateness, inasmuch as we both participate in the dance of life. Yet our full identification of each other can never be achieved. (Fromm 1976, p. 71)
>
> *Language* is an important factor in fortifying the having orientation. The name of a person – and we all have names (and maybe numbers if the present-day trend toward depersonalization continues) – creates the illusion that he or she is a final, immortal being. The person and the name become equivalent; the name demonstrates that the person is a lasting, indestructible substance – and not a process. Common nouns have the same function: i.e., love, pride, hate, joy give the appearance of fixed substances, but such nouns have no reality and only obscure the insight that we are dealing with processes going on in a human being. But even nouns that are names of *things*, such as "table" or "lamp," are misleading. The words indicate that we are speaking of fixed substances, although things are nothing but a process of energy that causes certain sensations in our bodily system. But these sensations are not *perceptions* of specific things like table or lamp; these perceptions are the result of a cultural process of learning, a process that makes certain sensations assume the form of specific percepts. We naively believe that things like tables and lamps exist as such, and we fail to see that society teaches us to transform sensations into perceptions that permit us to manipulate the world around us in order to enable us to survive in a given culture. Once we have given such percepts a name, the name seems to guarantee the final and unchangeable reality of the percept. (Fromm 1976, p. 67)
>
> If my *self* is constituted by what I *have*, then I am immortal if the things I have are indestructible. (Fromm 1976, p. 67)

It should be noted that the having mode of existence is by no means restricted to the possession of objects. As part of the Four Noble Truths, *tṛ́ṣṇa* (Sanskrit for desire or thirst), a cause of *dukkha* (unsatisfactoriness, suffering), is not primarily directed to material things.

> It is important to keep in mind that for Buddhism, the problem is not desire for material things; more fundamentally, desire is a thirst for ideas, theories (*dṛṣṭi*), since it is these that give us a sense of identity and define the values we impute to material things, such that we then find them desirable. [. . .] Those ideas, theories *(dṛṣṭi)* are part of the play of a linguistic-cognitive web of closure (*prapañca, āsava, anuśaya, saṃvṛti,* etc.). (Lusthaus 2002, p. 61)

Similarly, for *upādāna* (appropriation, grasping, clinging, attachment), the result of *tṛ́ṣṇa*, we have:

> We appropriate in order to expand, strengthen and affirm our selves. Self-definition, self-identification arises through appropriation. What is other either becomes mine, or else it serves as the boundary marker that circumscribes my limits, and thus what I am. The 'more' I possess, the 'greater' I am. (Lusthaus 2002, p. 65)

4 Language

An important element of Brouwer's philosophy is his position with respect to language, a position that has changed little throughout his life. It is also a major source of misunderstanding by the "bland and vapid views that have dominated the philosophy of mathematics," for it has been read in an absolute, un-nuanced sense. It is that misunderstanding that brands Brouwer with the "solipsist" label. We will see that, even though some might actively dislike it (Posy's "bugaboo"), it is by no means an idiosyncratic idea that sprung out of Brouwer's head and is not encountered in other reasonable minds.

That his views on language are of high relevance to his philosophy *of mathematics* and to his rejection of formalism and of logicism can be best read from his own explanation of the "first act of intuitionism":

> The *first act of intuitionism* completely separates mathematics from mathematical language, in particular from the phenomena of language which are described by theoretical logic, and recognizes that intuitionist mathematics is an essentially languageless activity of the mind having its origin in the perception of *a move of time,* i.e. of the falling apart of a life moment into two distinct things, one of which gives way to the other, but is retained by memory. If the two-ity thus born is divested of all quality, there remains the *empty form of the common substratum of all two-ities.* It is this common substratum, this empty form, which is the *basic intuition of mathematics.* (Brouwer 1952b, p. 509f)

His views can be summarized as follows: (i) language originates in will-transmission, in commands given to others, and thus of questionable morality as its original aim is to "break the will of others," making others obey; (ii) it is not, on its own, a means of communication, but in rare instances, it could become an aide in a communication that has been established by non-verbal means; (iii) language is very inadequate at expressing the inner life of a human being; (iv) language does not have the miraculous power of conjuring a life-like world, and it does not have a descriptive function in which it has shaken off the original sin of its birth as will-transmission; (v) even in the very restricted field of mathematics, language cannot

express faithfully the creations of a human subject, as these are living processes. Of these, (i), (iv), and (v) are insights that cannot be found expressed in such stark terms by other thinkers who find language inadequate. There is one mathematician who, after Brouwer, made a (v)-like statement. René Thom, another mathematician-philosopher, coming from an entirely different philosophical perspective, namely, that of mathematical Platonism, wrote in Thom (1970) (see also Papadopoulos 2018) that

> the world of ideas infinitely exceeds our "technical possibilities." It is in the intuition that the *ultima ratio* of our faith in the truth of a theorem resides. And, according to a now-forgotten etymology, a theorem is above all the object of a vision. (Thom 1970, p. 697)
>
> [Car le monde des Idées excède infiniment nos possibilités opératoires, et c'est dans l'intuition que réside *l'ultima ratio* (la raison dernière) de notre foi en la vérité d'un théorème – un théorème étant, selon une étymologie aujourd'hui bien oubliée, l'objet d'une vision.]

Already in Brouwer's earliest writing of 1905, the pamphlet *Life, Art, and Mysticism*, we read:

> The immediate companion of the intellect is language. From life in the intellect follows the impossibility of any form of direct communication with others – instinctively by gesture or looks, or even more spiritually through all separation of distance. People therefore start training themselves and their offspring in some crude sign language, painfully and with little success, for never has anyone been able to communicate with others, soul to soul. Language can only be the accompaniment of an already existing mutual understanding.
>
> [. . .]
>
> Only in the very narrowly restricted domains of the imagination such as in the exclusively intellectual sciences – which are completely separated from the world of perception and therefore touch the least upon the essentially human – only there can mutual understanding be maintained for some time. There is little scope for misunderstanding notions such as "equal" and "triangle," but even then two different people will never feel them in exactly the same way. Even in the case of the most restricted sciences, logic and mathematics – a sharp distinction between these two is hardly possible – no two different people will have the same conception of the fundamental concepts on which these two sciences are constructed; and yet their wills are parallel, and in both there is a small, unimportant part of the brain which forces their attention in the same way. (Brouwer 1996, p. 401)
>
> But ridiculous is the use of language when one tries to express subtle nuances of will which are not part of the living reality of those concerned, when for example so-called philosophers or metaphysicians discuss among themselves morality, God, consciousness, immortality, or the free will. These people do not even love each other, let alone share the same subtle movements of the soul; sometimes they even do not know each other personally. They either talk at cross-purposes or each builds his own little logical system which lacks any connection with reality. For logic is life in the human brain; it may accompany life outside the brain but it can never guide it by virtue of its own power. (Brouwer 1996, p. 401f)
>
> Words are no more than commando-signals [. . .] means of training and controlling
>
> All verbal utterances are more-or-less developed verbal imperatives, i.e. speaking can always be reduced to commands or threats, and understanding to obeying. (Van Stigt 1990, p. 197, unpublished papers)
>
> Language can accompany man's will to dominate the will of others or his will to keep the movements of wills together; for example, the war cry of Red Indians accompanies the will to break the will of others.

> Language by itself has no meaning; any philosophy which searched for a firm foundation based on that presumption has come to grief; lulled into sleep by the assurance of such firm foundation, one was rudely awakened by the appearance later of deficiencies and contradictions. A language which does not derive its certainty from the human will but which claims to live on in the 'pure concept' is an absurdity. (Brouwer 1996, p. 403)
>
> The practical reliability of the logical principles relies on the fact that a significant part of the world of intuition shows much more fidelity and satisfaction with respect to its finite organization than humanity itself. The fact that one has been, from time immemorial, blind to this sober interpretation, has been caused by the fact that the exclusive character of words as a means of will-transmission had not been recognized, and these were seen as a result of a rash superstition as suggestive means of fetish-like 'concepts'. These 'concepts' as well as the links existing between them, are supposed to have an existence independently of the causal stance of man, and the logical principles should represent the concepts and the a priori laws governing their connections. [Trans. V P.]
>
> [Die praktische Zuverlässigkeit der logischen Prinzipien beruht darauf, dass ein großer Teil der Anschauungswelt in bezug auf ihre endliche Organisation viel mehr Treue und Zufriedenheit zeigt als die Menschheit selbst. Dass man von alters her vor dieser nüchternen Interpretation blind war, wurde dadurch verursacht, dass man den ausschließlichen Charakter der Worte als Willensübertragungsmittel nicht erkannte und dieselben infolge eines unbesonnenen Aberglaubens als Andeutungsmittel fetischartiger 'Begriffe' betrachtete. Diese 'Begriffe' sowie die zwischen ihnen bestehenden Verknüpfungen sollten unabhängig von der kausalen Einstellung des Menschen eine Existenz besitzen, und die logischen Prinzipien sollten die Begriffe und ihre Verknüpfungen beherrschende aprioristische Gesetze darstellen. (Brouwer 1929, p. 423)]
>
> In default of a plurality of mind, there is no exchange of thought either. Thoughts are inseparably bound up with the subject. So-called communicating-of-thoughts to somebody, means influencing his actions. Agreeing with somebody, means being contended with his cooperative acts or having entered into an alliance. [. . .] By so-called exchange of thought with another being the subject only touches the outer wall of an automaton. This can hardly be called mutual understanding. Only through the sensation of the other's soul sometimes a deeper approach is experienced. And when wisdom revealed by the beauty of this sensation, finds expression in the antiphony of words exchanged, then there may be mutual understanding. (Brouwer 1948, p. 485)

These quotes encourage analytic philosophers to heap the usual verbal abuse, such as "solipsist," on Brouwer. This is a thorough misunderstanding of what Brouwer is writing *against.* What he writes against is a language that is viewed as possessing self-existence, as having content independently of the human mind, and as capable of transmitting that content. The rather mainstream Western view that language does have these miraculous powers is expressed by Franz Brentano, Gottlob Frege, Nicolai Hartmann, and Karl Popper.

In Hartmann (1964), Hartmann assigns to the spiritual (*das Geistige*) its own "real stratum" in the composition of the world, one which cannot be reduced to subjective consciousness. Subjective is only the carrying out of the act of thinking, the content of the thought itself is the spiritual content that is detachable from the subject and transferable, a fact without which communication between humans would not be possible. And Popper, whose engagement with Brouwer's thought is surveyed in (Naraniecki 2015), finds that

> we may distinguish the following three worlds or universes: first, the world of physical objects or physical states; secondly the world of states of consciousness or of mental states, or perhaps of behavioural dispositions to act; and thirdly the world of *objective contents of thought*, especially of scientific and poetic thoughts and of works of art. (Popper 1967, p. 106)

Popper finds that his "third world" has "more in common still with Bolzano's theory of a universe of propositions in themselves and of truths in themselves" and "resembles most closely the universe of Frege's objective contents of thought" (Popper 1967, p. 106). He argues for "the independent existence of the third world" (Popper 1967, p. 107). "Theories or propositions or statements are the most important third-world linguistic entities" (Popper 1968, p. 157). "The activity of understanding consists, essentially, in operating with third-world objects" (Popper 1968, p. 164).

The Buddha finds that such a separation of the contents of the second and third worlds is impossible:

> Feeling, perception, and consciousness, friend – these states are conjoined, not disjoined, and it is impossible to separate each of these states from the other to describe the difference between them. For what one feels, that one perceives, and what one perceives, that one cognizes.
>
> Wisdom and consciousness, friend – these states are conjoined, not disjoined, and it is impossible to separate each of these states from the other to describe the difference between them. For what one wisely understands, that one cognizes, and what one cognizes, that one wisely understands.
>
> [. . .] wisdom is to be developed, consciousness is to be fully understood. (Nanamoli and Bodhi 1995, Mahāvedalla Sutta, pp. 388–389 (PTS M i 292–293)]

While the Buddha mentions a "theory" that does not depend on human discovery, namely, the doctrine of *dependent arising* (or *dependent origination*) (see Kalupahana 1975), its content, when clothed in language, is subject to the vicissitudes that visit any language-composed doctrine practiced by humans. It is due to precisely the historical destiny of all such doctrines that he prophesized the demise of the *dharma* in India (see Lamotte (1976, p. 210f) for more details).

> And what, bhikkhus, is dependent origination? "With birth as condition, aging-and-death [comes to be]": whether there is an arising of Tathāgatas or no arising of Tathāgatas, that element still persists, the stableness of the Dhamma, the fixed course of the Dhamma, specific conditionality. A Tathāgata awakens to this and breaks through to it. (Boddhi 2000, II.25, Nidānasaṃyutta, p. 551)

As pointed out by David Kalupahana, language, as understood by the Buddha, does not work on its own, in the absence of what Brouwer calls "an already existing mutual understanding."

> Language cannot be a means of communication unless the language users agree upon the various elements of a language as being expressive of their experiences. Thus, agreement or concurrence *(sammuti)*, whether it be of a small group or of the world *(loka)* at large, is an

> important characteristic of language. The use of the term *sammuti*, which implies agreement in the sense of "thinking together," makes language not merely a behavioural phenomenon but a psychological one as well. (Kalupahana 1999, p. 52)

The "propositions in themselves," the "truths in themselves," the "objective contents of thought," and, in general, "third-world objects" claim a *svabhāva* existence (*self-nature* in Kalupahana's translation, *own being* in Robinson's translation), which is not only found to be contradictory in Chap. XV (Examination of Self-Nature) of Nāgārjuna's *Mūlamadhyamakakārikā* (for the extent to which mādhyamika can be seen as a critique of language (see Napper (1989, pp. 75–100)):

> *Svabhāva* is by definition the subject of contradictory ascriptions. If it exists, it must belong to an existent entity, which means that it must be conditioned, dependent on other entities, and possessed of causes. But a *svabhāva* is by definition unconditioned, not dependent on other entities, and not caused. Thus the existence of a *svabhāva* is impossible. (Robinson 1957, p. 299)

but is also considered by the Buddha and his followers to be the origin of all mental confusion:

> The root of all the troubles of cyclic existence and solitary peace is the ignorance conceiving true existence, as well as its predispositions. (Gyatso 1990, p. 78)

If I think in terms of "contents of thought," this objectifying process allows ownership of that "content." If thoughts are fleeting by their very nature, are inseparably bound up with the subject, and disappear with the subject, then they are of no value in the having mode of existence.

Similar thoughts on the inadequacy of language were expressed not just by Erich Fromm but also by a wide variety of twentieth-century thinkers. Here is what the founder of "general semantics" had to say on the matter:

> Words *are not* the things they represent. (7)
>
> The above [. . .] considerations lead to unexpectedly far-reaching consequences.
>
> From (7) – it follows that the objective levels which include the events, ordinary objects, objective actions, processes, immediate feelings, 'instincts', 'ideas', [. . .] represent un-speakable levels, *are not words*. (9)
>
> From (9) – that the use of the 'is' of *identity*, as applied to objective, un-speakable levels, appears invariably structurally false to facts and must be entirely abandoned. Whatever we might say a happening 'is', it *is not;* (10)
>
> From (10) – *structure* appears as the only possible link between the objective, unspeakable, and the verbal levels. (11)
>
> From (11) – the only possible 'content of knowledge' becomes exclusively *structural.* (12)
>
> From (12) – the only aim of 'knowledge' and science appears as the empirical search for, and verbal formulation of, structure.
>
> The only method for acquiring 'knowledge' is found in an empirical investigation of the potentially unknown structure of the world, ourselves included, only afterwards adjusting the structure of languages so that they would be similar, and so of maximum usefulness;

> instead of the delusional reversed order of ascribing to the world the structure of an inherited primitive language. (Korzybski 1931, p. 751f)

Although Krishnamurti does not explicitly refer to the will-transmission character of language, it is implicit when he admonishes his audiences repeatedly that the speaker, although on a podium, tries to figure out the answer to a question *with his audience*, that all following of someone else's advice on matters of wisdom, life, love, ethics, or meditation is counter-productive, for only oneself can discover for oneself the truth of those, that all else is "conditioning." "There is no right *guru*. There is only wrong *guru*, because nobody can teach you anything except for yourself. [. . .] nobody can teach you what you are" (Krishnamurti and Bohm 1983). He also sees the will-transmission component when language is not even used between two people but rather in a monologue, as in the traditional approaches to "meditation":

> Who is meditating? In most systems of meditation, Japanese, Indian, Tibetan, and so on, there is the controller and the controlled. The controller tries to control thought, quieten thought, shape it according to a purposeful direction.
>
> [. . .]
>
> The speaker has gone into this for the last sixty years or more. He has discussed this question with Zen pundits, with Hindus, Tibetans and all the rest of the gang, and he refutes that kind of meditation because their idea of meditation is to achieve an end. The end being complete control of the brain so that there is no movement of thought. Because when the brain is still, deliberately disciplined, deliberately sought after, it is not silent. It is like achieving something, which is the action of desire. (Krishnamurti 1984)

Krishnamurti is also very clear about the inadequacy and the limitations of language:

> Understanding is not verbal, nor is there such a thing as intellectual understanding. Intellectual understanding is only on the verbal level, and so no understanding at all. Understanding does not come as a result of thought, for thought after all is verbal. (Krishnamurti 1956, p. 194)
>
> Sir, love is not a word; the word is not the thing, is it? God is not the word "god," love is not the word "love." But you are satisfied with the word, because the word gives you a sensation. When somebody says "God," you are psychologically or nervously affected, and that response you call the understanding of God. So, the word affects you nervously and sensuously, and that produces certain action. But the word is not the thing, the word "god" is not God; you have merely been fed on words, on nervous, sensuous responses. Please see the significance of this. How can you act if you have been fed on empty words? For words are empty, are they not? They can only produce a nervous response, but that is not action. Action can take place only when there is no imitative response, which means the mind must enquire into the whole process of verbal life. (Krishnamurti 1991, Bangalore fourth public talk July 25, 1948)
>
> Can we say the word is not the thing? Whatever the description, it is not the real, not the truth, however much you embellish or diminish it. We recognize that the word is not that, then what is there beyond all this? Can my mind be so desireless that it won't create an illusion, something beyond? (Krishnamurti and Bohm 1999, p. 121)
>
> Naming only strengthens and gives continuity to the experiencer, to the desire for permanency, to the characteristic of particularizing memory. There must be silent awareness

> of naming, and so the understanding of it. We name not only to communicate, but also to give continuity and substance to an experience, to revive it and to repeat its sensations. This naming process must cease, not only on the superficial levels of the mind, but throughout its entire structure. This is an arduous task, not to be easily understood or lightly experienced; for our whole consciousness is a process of naming or terming experience, and then storing or recording it. It is this process that gives nourishment and strength to the illusory entity, the experiencer as distinct and separate from the experience. Without thoughts there is no thinker. Thoughts create the thinker, who isolates himself to give himself permanency; for thoughts are always impermanent. (Krishnamurti 1956, p. 69)

Here is what Albert Schweitzer wrote on the possibility of understanding one another:

> None of us can claim that we really know another person, even if we have lived together with that person every day for years. Of what makes up our inner experience, we cannot communicate even to our closest others more than fragments. We can neither give the entirety of that experience nor could the others grasp it. We walk in a half darkness, in which neither can recognize the other's features accurately. Only from time to time, through an experience we had with our companion, or through a word that falls between us, does the other stand next to us for a moment, as if illuminated by a lightning bolt. That's when we see him as he is. Afterwards we'll go again, perhaps for a long time, side by side in the dark and try in vain to imagine the other's features. (Trans. V. P.)
>
> [Keiner von uns darf behaupten, daß er einen andern wirklich kenne und wenn er seit Jahren täglich mit ihm zusammen lebt. Von dem, was unser inneres Erleben ausmacht, können wir auch unseren Vertrautesten nur Bruchstücke mitteilen. Das Ganze vermögen wir weder von uns zu geben, noch wären sie imstande, es zu fassen. Wir wandeln in einem Halbdunkel, in dem keiner die Züge des anderen genau erkennen kann. Nur von Zeit zu Zeit, durch ein Erlebnis, das wir mit dem Weggenossen haben, oder durch ein Wort, das zwischen uns fällt, steht er für einen Augenblick neben uns, wie von einem Blitze beleuchtet. Da sehen wir ihn, wie er ist. Nachher gehen wir wieder, vielleicht für lange, im Dunkel nebeneinander her und suchen vergeblich, uns die Züge des andern vorzustellen. (Schweitzer 1974, p. 385f)]

And here is what two neurobiologists wrote about communication by means of language (one of them, Francisco Varela, was a co-founder of the *Mind and Life Institute* to promote dialog between science and Buddhism, so guilty by association of accepting the validity of the *Eastern* approach):

> So long as language is considered to be denotative it will be necessary to look at it as a means for the transmission of information, as if something were transmitted from organism to organism, in a manner such that the domain of uncertainties of the 'receiver' should be reduced according to the specifications of the 'sender'. However, when it is recognized that language is connotative and not denotative, and that its function is to orient the orientee within his cognitive domain without regard for the cognitive domain of the orienter, it becomes apparent that there is no transmission of information through language. It behooves the orientee, as a result of an independent internal operation upon his own state, to choose where to orient his cognitive domain; the choice is caused by the 'message', but the orientation thus produced is independent of what the 'message' represents for the orienter. In a strict sense then, there is no transfer of thought from the speaker to his interlocutor; the listener creates information by reducing his uncertainty through his interactions in his cognitive domain. Consensus arises only through cooperative interactions in which the

> resulting behavior of each organism becomes subservient to the maintenance of both. (Maturana and Varela 1980, p. 32)

And here is a quote from Henri Poincaré about language, quoted at the end of Brouwer (1913):

> People do not understand each other because they do not speak the same language and because there are languages that cannot be learned. (Trans. V. P.)
>
> [Les hommes ne s'entendent pas, parce qu'ils ne parlent pas la même langue et qu'il y a des langues qui ne s'apprennent pas. (Poincaré 1913, p. 161)]

All of Brouwer's utterances on language are taken literally and absolutely by Brouwer's detractors, who deliberately refuse to take notice of the fact that the same person who wrote dismissively about the capabilities of language to provide *exact* communication by means of "objective contents of thought" and wrote about its inherent limitations, was involved in the significs project and was a master of a highly evocative language, as related in a recollection of Mannoury's daughter.

> Mrs. Vuysje, the daughter of Mannoury, described Brouwer's conversation as an almost artistic process: Brouwer could in the middle of a sentence pause to savour a particular expression, and to replace it after consideration by a more suitable one. She remembered him, standing in the garden stretching out his hand, tasting a particular word and contemplating fitting equivalents. The result was not a faltering flow of words; Brouwer had mastered the technique of refinement to such a degree that he managed to produce gentle, flowing sentences of incredible length without discernible interruptions. (Van Dalen 2013, p. 263)

Not even in this area is Brouwer given his due. Reviewing Van Stigt (1990), Smoryński mentions that he could not make any sense of Van Stigt's remark that "Brouwer lacked the ability to express his feelings artistically," for it "certainly runs counter to what every Dutchman I've spoken to has said of Brouwer's correspondence with Adama van Scheltema: Brouwer's prose is uniformly favourably compared with that of the poet" (Smoryński 1994, p. 802). There are, however, mathematicians and philosophers who did not fall into the trap of concluding "solipsism" or "bugaboo" from Brouwer's writings on language. In addition to the works already mentioned by Largeault and Detlefsen, Van Dalen (1999a), Placek (1999), and Kaneko (2002a) treat this aspect of Brouwer's philosophy in earnest, and none come to the negative conclusions mentioned in the Introduction. Placek (1999) disproves that Brouwer was a solipsist and shows that intersubjectivity is possible in Brouwer's philosophy.

There is one more restricted use Brouwer finds for language; it is that of a memory aide.

> Even if language in its origin and in the first place is a function of the activity of social man it plays a significant role also in the reflective thinking and mnemotechnical processes of the solitude of singular man. (Brouwer 1933; Van Stigt 1990, p. 422f)

We can say that, while Brouwer realizes that, unfortunately, language is not a means for mutual understanding, is endowed with an original sin that renders its use morally questionable, we have no choice but to try the impossible. As Verena Huber-Dyson put it:

> Formalization and Poetry are the two most direct means we have of externalizing our thoughts. (Huber-Dyson 1996, p. 67)

Brouwer chose poetry, for at least it has no pretension to convey anything *exactly*, and opts for hinting at a state of mind, a feeling, or an atmosphere. This he found, in his own experience as a student at the University of Amsterdam, listening to Gerrit Mannoury, more helpful than the precision of strings of symbols. Brouwer finds that one is, by the very nature of language, in the Sisyphean, absurd hero position of making, while being thrown upon the use of language, a desperate use of a tool ill-suited for the task, much like a character in Franz Kafka's world, as seen by Albert Camus:

> Kafka's world is in truth an indescribable universe in which man allows himself the tormenting luxury of fishing in a bathtub, knowing that nothing will come of it. (Camus 1955)
>
> [Le monde de Kafka est à la vérité un univers indicible où l'homme se donne le luxe torturant de pêcher dans une baignoire, sachant qu'il n'en sortira rien.]

5 The Eastern Origin of Subjective Idealism

Why is subjective idealism so scandalous in Western philosophy concerned with mathematics? After all, Schopenhauer made statements that put him squarely in the subjective idealist, decidedly *Eastern*, camp, such as

> On the other hand, the Kantian teaching, even without the antinomies, leads to the insight that things and their whole mode and manner of existence are inseparably associated with our consciousness of them. Therefore he who has clearly grasped this soon reaches the conviction that the assumption that things exist as such, even outside and independently of our consciousness, is really absurd. [Trans. E. F. J. Payne]
>
> [Hingegen leitet die Kantische Lehre, auch ohne die Antinomien, zu der Einsicht, daß die Dinge und die ganze Art und Weise ihres Daseyns mit unserm Bewußtseyn von ihnen unzertrennlich verknüpft sind; daher wer Dies deutlich begriffen hat, bald zu der Ueberzeugung gelangt, daß die Annahme, die Dinge existierten als solche auch außerhalb unseres Bewußtseyns und unabhängig davon, wirklich absurd ist. (Schopenhauer 1859, Erstes Buch, Kap. 1, p. 708)]

and this did not prevent him from being influential for a while, nor did Emerson's embrace of subjective idealism (Lyttle 1997) harm his position in American letters and philosophy.

That someone presenting general advice on life, ethics, or, in general, what usually goes for wisdom, embraces subjective idealism presents no threat to the

main pride of Western philosophy: mathematics and evolution. What is scandalous and asks for the entire arsenal of derision, belittling, and name-calling in Brouwer's case is the proposal as the only sound basis for mathematics, a jewel of the Western philosophical approach, of an unmistakably Eastern foundation.

As was observed by Aram Frenkian in 1946, there is not a hint of subjective idealism in any Greek philosophical work that precedes the contact with the East brought about by Alexander. He detected in Frenkian (1946) the first text suggestive of subjective idealism in the Memphite Theology, as inscribed on the Shabaka Stone (see Allen (1988), Hoffmeier (1983), and Finnestad (1976) for a detailed study of its contents), which dates from the 25th dynasty of Egypt. There we are told that "Great and important is Ptah,// who gave life to all the gods and their *kas* as well// through this heart and this tongue" (Allen 1988, p. 43). Similar utterances can be found in earlier previous Egyptian texts, such as the Coffin Texts (Allen 1988, p. 45) (late 18th or early 19th dynasty). The conclusions Allen draws in (Allen 1988, pp. 56–61) regarding the subjective idealist nature of Egyptian thought and cosmology, a "construct of opposites in balance" (Allen 1988, p. 57), without citing Frenkian (1946) or Haas (1956), can be taken to be an added, independent confirmation of Frenkian's thesis.

The appearance of something akin to subjective idealism, in various *mind-only* schools of Mahāyāna Buddhism, has been the subject of several studies, such as Guenther (1989), Suzuki (1998), and Lusthaus (2002). Perhaps the most telling line is one by Nāgārjuna, who states:

> The [material world], in the final analysis, cannot exist. (Inagaki 1998, Chap. 33, p. 124)

The first appearance of a "vacillation" between "the ontic-ontological aspect" and "its mentalist-idealist aspect" (McEvilley 1980, p. 181) in the world of Greek letters can be detected in the philosophy of Plotinus, the first Greek philosopher who is seen similar to, on the one hand, an Indian current of thought of the subjective idealism variety, Vijñānavāda Buddhism, and, on the other hand, to an Indian version of objective idealism, the Upanishadic-Vedāntic philosophy, in the opus magnum comparing Greek and Indian thought (McEvilley 2002, Chaps. 22 and 23) (cf. also Sabo 2017). The dearth of reports of Greek philosophers traveling East before Alexander's conquests, mentioned in Männlein-Robert (2009), indicates that Greek philosophers of pre-Hellenistic times were unaware of the very existence of subjective idealist thought.

Subjective idealism is very rare in the history of Western philosophy. Although Berkeley was labeled by Kant and Hegel as a subjective idealist, that designation is, given the role played by God in his philosophy, certainly not accurate, as pointed out in Callahan (2015).

The varieties of idealism favored in Western philosophy tend to leave the physical world in its place. Husserl emphasized in his *Die Krisis der europäischen Wissenschaften und die transzendentale Phänomenologie* the *European* roots of his transcendental phenomenology not just because the year in which the lectures were held was 1936 and he had been branded non-Aryan but, as pointed out in

(Majer 2010), because the roots of his philosophy are unmistakably Western. In fact, there is a version of Husserl minus idealism, developed by one of his students, Ingarden (1975), which is viable. In that sense, the philosophy favored for comparisons with Brouwer escapes the anathema of an Eastern origin.

6 Brouwer's View on Mathematics

As we have seen, the first act of intuitionism distinguishes mathematics from the language of mathematics; establishes the source of mathematics, which is an intuition, the intuition of time; and establishes the nature of the mathematical activity, which is a "languageless activity of the mind." This is Brouwer's version of Fromm's "Being refers to *experience*, and human experience is in principle not describable."

The second act of intuitionism defines the intuitionistic continuum in terms of choice sequences, which are freely chosen sequences of rational numbers.

We will first look at the wide-ranging consequences of the first act. The first part, the statement that mathematics is not to be confused with the language of mathematics, might seem the most shocking. Brouwer provides the following comparison to explain why the two are distinct: "the formal language which accompanies mathematics as the weather-map accompanies the atmospheric processes" (Brouwer 1937, p. 451). We have seen that René Thom expressed similar views on the inability of our *possibilités opératoires* of expressing the world of our ideas in Thom (1970, p. 697). Needless to say, the support comes from a counter-modern, who looked to Aristotle for guidance, followed none of the intellectual fashions of his time, and asked his daughter, then just a child, excited about the events of May 1968: "Mais où prends-tu qu'après une révolution les choses iront mieux?" (Papadopoulos 2018) ["But where did you get it that after a revolution things will get better?" (Trans. V. P.)]

Brouwer is very explicit on the difference between mathematics and the language of mathematics, both in the sense that there is language-specific rubbish that he does not count as mathematics and that there exists ineffable mathematics, making its communication impossible.

> [. . .] I do not recognize as true, hence as mathematics, everything that can be written down in symbols according to certain rules, and conversely I can conceive mathematical truth which can never be fixed down in any system of formulas. (Brouwer 1937, p. 452)
>
> Thus for a human mind equipped with an unlimited memory, pure mathematics, practised in solitude and without using linguistic signs, would be exact, but the exactness would be lost in mathematical communication between human beings with an unlimited memory, because they would still be thrown upon language as their means of understanding. (Brouwer 1933, p. 443)

Although we have seen that other thinkers deny language the ability to express certain processes, it is mostly our inner lives that are deemed ineffable by Fromm or Schweitzer. On the other hand, even something that has been clothed in language cannot be decoded by a naive reading, as pointed out by Dilthey, who asks for

special faculties, such as *Verstehen* (understanding) for the very comprehension of literary textual material, for which the reader needs the abilities of *Hineinversetzen*, *Nachbilden*, *Nacherleben* (Dilthey 1965, pp. 213–216) [putting oneself in somebody else's position, replicating, reliving]. In other words, texts do not communicate by means of a simple transmission of sequences of words. Yet one would perhaps think that mathematics is far removed from these texts belonging to the humanities, that comprehension is straightforward, requires no *Verstehen* in Dilthey's sense, because mathematics is not about human life. If, however, mathematics is a "languageless activity of the mind," then it *is* subject to the same communication difficulties a literary text encounters. Things are further complicated by the fact that

> Mutual understanding between two people is a matter of degree, but in mathematics their mutual understanding is either total or it does not exist, like being-asleep, one either is or is not. (Van Stigt 1990, p. 208, unpublished manuscript]

On an empirical level, anyone who has tried to teach mathematics has been confronted with this issue, as have university administrators who have thought that recording the teaching of a course by a luminary would enable tens of thousands to learn the content of that course. The same holds for the purported proof of the *abc*-conjecture or for the highly complex mathematics of our time, in which certain subjects are understood by no more than a dozen people, and it is practically impossible to learn those subjects from texts. One needs to be present in the centers where there are experts in them. This is a version of Polanyi's "we can know more than we can tell" (Polanyi 2009, p. 4).

When Brouwer refers to "everything that can be written down in symbols according to certain rules," he means what he called in Brouwer (1913) *formalism.* The name refers to Hilbert's understanding of the foundations of mathematics, although Hilbert never used the term. Hilbert understood, for the purposes of proof theory, a mathematical theory as consisting of a set of axioms expressed in a formal language, together with a set of rules of inference, which allow the deduction of new sentences from the axioms. All sentences are just strings of meaningless symbols, satisfying certain syntactic rules. The name "formalism" turned out to be a very popular one and has been in use by everyone except Hilbert and members of his inner circle up to the present day. Hilbert would say that he does not mean that mathematics is concerned with deriving meaningless strings of symbols from other meaningless strings of symbols, that this is just a tool for reaching certain meta-mathematical goals. However, formalism is, nowadays, the official foundation of mathematics. The other competing foundation, logicism, which claimed that mathematics is a part of logic, has faded away, as it was not able to account for modern algebra or even for geometry, as noticed by Bertrand Russell himself, a major proponent of logicism (Gandon 2012; Musgrave 1977).

Now, even this highly controlled and unambiguous language is, in Brouwer's view, fraught with the shortcomings of any language.

> There is neither exactness nor certainty for will-transmission, especially for one mediated through language. And this state of affairs remains undiminished if will-transmission refers to the construction of purely mathematical systems. *So even for pure mathematics there is no certain language*, i.e., no language that excludes misunderstandings in conversation and protects from mistakes in the act of memory support (i.e. from the confusion of different mathematical entities). This circumstance cannot be remedied, in the manner done by *the formalistic school*, that one subjects the mathematical language (i.e. the system of signs that is used to evoke purely mathematical constructions in other people) itself to a mathematical examination, confers it through reworking the accuracy and stability of a material instrument or a phenomenon of exact science and in so doing communicates in a second-order language or metalanguage about it. (Trans V. P.)
>
> [Nun gibt es aber für Willensübertragung, insbesondere für durch die Sprache vermittelte Willensübertragung, weder Exaktheit, noch Sicherheit. Und diese Sachlage bleibt ungeschmälert bestehen, wenn die Willensübertragung sich auf die Konstruktion reinmathematischer Systeme bezieht. *Es gibt also auch für die reine Mathematik keine sichere Sprache*, d. h. keine Sprache, welche in der Unterhaltung Mißverstandnisse ausschließt und bei der Gedächtnisunterstützung vor Fehlern (d. h. vor Verwechslungen verschiedener mathematischer Entitäten) schützt. Diesem Umstande ist nicht dadurch abzuhelfen, daß man, wie es die *formalistische Schule* macht, die mathematische Sprache (d. h. das zur Hervorrufung reinmathematischer Konstruktionen bei anderen Menschen dienende Zeichensystem) selber einer mathematischen Betrachtung unterzieht, ihr durch Umarbeitung die Genauigkeit und Stabilität eines materiellen Instrumentes oder eines Phänomens der exakten Wissenschaft verleiht und sich dabei in einer Sprache zweiter Ordnung oder Übersprache über sie verständigt. (Brouwer 1929, p. 421f)

Now, what could be the ineffable mathematical truths Brouwer referred to? I thought it was some truth belonging to geometric topology, given that I always felt that the idea that geometric topology could be formalized is a pious wish. The fact that Thom, another geometric topologist, stated the same belief in ineffable mathematical truths seems to provide additional support. Van Dalen (Van Dalen 1999a) thinks that choice sequences, which are unfinished objects, were what Brouwer had in mind.

Also part of the first act is the realization that mathematics originates in intuition, in particular in a *single* intuition, that of time, "a single aprioristic basic intuition, which may be called invariance in change as well as unity in multitude" (Brouwer 1907, p. 97). That arithmetic originates in [the intuition of] time was stated by Meister Eckhart as well.

> The one is eternity, which always holds itself alone and is without change. However, the two, that is time, which changes and multiplies itself. (Trans. V. P.)
>
